ON POISONS
IN RELATION TO MEDICINE AND MEDICAL JURISPRUDENCE.
MEDICAL JURISPRUDENCE.

BY

ALFRED SWAINE TAYLOR, M.D. F.R.S.

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS; HON. M.D. UNIV. ST. ANDREWS; MEMBER OF THE ROYAL COLLEGE OF SURGONS; PROFESSOR OF MEDICAL JURISPRUDENCE AND CHEMISTRY IN GUY'S HOSPITAL; AND EXAMINER IN CHEMISTRY TO THE UNIVERSITY OF LONDON AND THE ROYAL COLLEGE OF VETERINARY SURGONNS.

Nisi utile est quod facimus, stulta est gloria.

SIXTH EDITION.

LONDON:

JOHN CHURCHILL, NEW BURLINGTON STREET.

MDCCLXVIII.
PREFACE

to

THE SIXTH EDITION.

In the revision of the sixth edition of this work, I have made such additions as the advance of science and experience derived from recent cases, have rendered necessary. Since the publication of the fifth edition, there has been a large accumulation of materials in Medical Jurisprudence; but the limits of this work have rendered it necessary that I should confine myself to a selection of the more important facts and cases. Even with this limitation, the present volume extends to forty-four pages beyond the fifth edition, and to three hundred pages beyond the first edition published in November 1848. In fact, when compared with the early editions, this may be regarded as a new work. I do not mean that the principles or facts of the science are materially changed; but during the last fourteen years, improvements in medicine and jurisprudence have taken place to so great an extent, that a practitioner whether of the medical or legal profession would, in the earlier editions, meet with deficiencies which on the present occasion it has been my special object to supply.

In the section on Poisons, a modification of the definition of the term poison and of the act of poisoning has been rendered necessary by crimes of recent date. Additions have been made on poisoning by ammonia, — chronic poisoning by arsenic, — the absorption and detection of arsenic in the dead body, — poisoning by arsine-fretted hydrogen, — the detection of absorbed
mercury,—poisoning by Scheele’s green, tartar emetic, locust beans, prussic acid, nux vomica, and strychnia. The chapter on the two last-named poisons has been entirely rewritten. The reader will also find additional facts and cases in the sections on poisoning by cenanthe crocata, aconite, and lobelia. The details regarding poisons are, however, given throughout in a concise form, as constituting only a part of the general science of Medical Jurisprudence. A new edition of my work on Poisons is already far advanced, and to this I must refer the reader for that special information on facts, whether of a legal, medical, or medico-legal kind, which belong to the subject of Toxicology.

In the section on Wounds, the additions include the rules respecting dying declarations made to medical men,—the detection of blood on weapons and clothing,—the medico-legal examination of wounds,—the microscopical and chemical analysis of blood,—cicatrices,—locomotion after severe injuries,—and the effects of concussion of the brain and spinal marrow, illustrated by recent cases.

Additional facts have been introduced into the sections on PREGNANCY, DELIVERY, and ABORTION; and new cases are appended to the subjects of Tenancy by Courtesy, Protracted

MEDICAL JURISPRUDENCE.

POISONING.

CHAPTER I.

DEFINITION OF THE TERM POISON — LEGAL DEFINITION — MEANING OF THE WORDS DEADLY POISON—MECHANICAL IRRITANTS—INFLUENCE OF HABIT AND IDIOSYNCRASY ON POISONS —CLASSIFICATION OF POISONS — SPECIAL CHARACTERS OF IRRITANTS, AND NEUROTIC POISONS.

Definition.—A Poison is commonly defined to be a substance, which, when administered in small quantity, is capable of acting deleteriously on the body, and in popular language, it is applied to those substances only which destroy life in small doses. It is obvious that this definition is too restricted for the purposes of medical jurisprudence. It would, if admitted, exclude numerous substances, the poisonous properties of which cannot be disputed—as, for example, the salts of copper, tin, zinc, lead, and antimony; these, generally speaking, act only as poisons when administered in very large doses. Some substances, such as nitre, have not been known to act as poisons except when taken in large doses, while arsenic acts as poison in small doses; but in a medico-legal view, whether a man dies from the effects of half an ounce of nitre, or of two grains of arsenic, the responsibility of the person who criminally administers the substance is the same. Each must be regarded as a poison, differing from the other only in its degree of activity, and perhaps in its mode of operation. The result is the same; death is caused by the substance taken, and the quantity required to kill cannot therefore be made a ground for distinguishing a poisonous from a non-poisonous substance. If, then, a medical witness be asked “What is a poison?” he must beware of adopting this popular definition, or of confining the term poison to a substance which is capable of operating as such in a small dose given at once.

The fact that a poison has been commonly regarded as a sub-
stance which produces serious effects when taken in small quantity, has induced many who have adopted this arbitrary view to assert, that certain substances which have actually been known to cause death, are not poisons; and this doctrine is apparently supported by the inference, that were not some such distinction adopted, it would be difficult to separate the class of poisons from bodies which are reputed inert. In answer to this view, it is perhaps sufficient to show, that there is no good reason for assuming this as the distinguishing character of a poison; for it is impossible, even among substances universally admitted to be poisonous, to make any division among them according to the effects produced by the quantity taken. In relation to the quantity required to operate fatally, the difference is not so great between cream of tartar and oxalic acid as between oxalic acid and strychnia.

In legal medicine, it is difficult to give such a definition of a poison as shall be entirely free from objection. Perhaps the most comprehensive which can be suggested is this:—"A poison is a substance which, when taken internally, is capable of destroying life without acting mechanically on the system." But it is well known that some substances act as poisons by absorption when applied either to the skin or to a wounded surface; while others, again, as the poison of the viper, and of rabies, may have their fatal effects limited to those cases in which they are introduced by a wound: and a third class may destroy life merely by their chemical effects upon the parts with which they come in contact, without necessarily poisoning the blood by absorption; e.g. sulphuric acid. These facts show that it is very difficult to comprise in a few words an accurate description of what should be understood by the term "poison."

It is not easy to define the boundary between a medicine and a poison. It is usually considered that a medicine in a large dose is a poison, and a poison in a small dose is a medicine; but a substance may have a medicinal or poisonous action on the system not only according to the dose, but according to the frequency with which it is repeated. Thus, while a large dose of tartarized antimony (sixty grains) has been known to destroy life, a smaller quantity than this given in repeated doses at intervals, may prove equally destructive. Several cases have occurred since the former edition of this work which show that life may be thus destroyed by the criminal use of medicinal doses of tartarized antimony. (See Gay's Hospital Reports, Oct. 1857.) This remark applies to a great number of medicines which are not commonly included in a list of poisons.

Legal definition.—In reference to the medical definition of a poison, it is necessary to observe that the law never regards the manner in which the substance administered acts. If it be capable of destroying life or of injuring the health of an individual, it is
of little consequence, so far as the responsibility of a prisoner is concerned, whether its action on the body be of a mechanical or chemical nature. Thus a substance which simply acts mechanically on the stomach, may, if wilfully administered with intent to injure, involve a person in a criminal charge, as much as if he had administered arsenic or any of the ordinary poisons. It is, then, necessary that we should consider what the law strictly means by the act of poisoning. If the substance criminally administered destroy life, whatever may be its nature or mode of operation, the accused is tried on a charge of murder or manslaughter, and the duty of the medical witness consists in showing that the substance taken was the certain cause of death. If, however, death be not a consequence, then the accused is tried under a particular statute for the attempt to murder by poison (1 Vict. c. 85, sec. 2). The words of this statute are very general, and embrace all kinds of substances, whether they be popularly or professionally regarded as poisons or not. Thus it is laid down that—

"Whoever shall administer, or cause to be taken by any person, any poison, or other destructive thing, with intent to commit murder, shall be guilty of felony, and being convicted thereof, shall suffer death."

Although the administering be followed not by death but only by bodily injury dangerous to life, it is still a capital felony, provided the intent have been to commit murder. The attempt to administer to any person, any poison or other destructive thing, with the like intent, &c., although no bodily injury be effected, is felony, punishable by transportation for life, for fifteen years, or imprisonment for any term not exceeding three years. From the words of the statute it appears that the law requires, in order to constitute the crime of poisoning, that the substance should be administered to, or be taken by, an individual. Several deaths have been caused of late years by the external application of arsenic and corrosive sublimate to ulcerated and diseased surfaces. Supposing that a poison is thus applied intentionally, and great bodily injury is done to an individual, it might be a question whether the crime could be punished under these sections of the statute. Lord Campbell's act (14 and 15 Vict. c. 19) appears to provide for this description of offence, although the application or administration is herein limited to chloroform, laudanum, or other stupefying drug. The external application of arsenic in a way to produce personal injury would no doubt be considered an act of administration.

It will be perceived that the words of the statute leave the question "what is a poison" to depend upon the medical evidence adduced. In a trial which took place at the Chelmsford Assizes, a woman was charged with administering White precipitate to her husband with intent to kill. She was acquitted on
the ground that there was no evidence to show that white precipitate was either a poison or a destructive thing. It is, however, placed beyond doubt that this substance is not only capable of producing noxious effects, but of destroying human life; hence, this acquittal was based on a pure mistake. White precipitate is not by any means so poisonous as corrosive sublimate, but it is undoubtedly a mercurial poison. *White hellebore, Lobelia inflata, and Oil of turpentine* have been erroneously pronounced not to be poisons under similar circumstances; in fact, unless the medical evidence received by a Court when this question is raised, be very closely investigated, the greatest mistakes may arise, owing perhaps to want of experience or want of reflection on the part of those to whom the question is put.

The quantity of a poisonous substance found in an article of food, or in a dead body, does not affect the culpability of a person indicted for administering it. In the case of *Harley* (C.C.C. May 12, 1850), in which an attempt was made to administer sulphuric acid mixed with coffee, Mr. Justice Creswell stated —if poison be administered with intent to murder, it is not necessary there should be enough in the article administered to cause death. If any poison be there, and the intent be proved, the crime of attempting to administer poison is complete. Erle J. ruled to the same effect, in reference to the discovery of a small quantity of arsenic in a dead body, in the case of *Reg. v. Bacon* (Lincoln Summer Assizes, 1857). In the case of *Reg. v. Southgate* (Chelmsford Lent Assizes, 1849), Baron Parke said, in reply to an objection taken, it was quite immaterial to define or prove in what vehicle a poison was given, or whether it was administered in a solid or liquid form.

This question, "What is a poison?" may present itself under another aspect. In the *Queen v. Cluderay* (Exchequer Chamber, January 19, 1849), the prisoner was indicted for administering poison with intent to murder. He was proved to have administered to a child nine weeks old, two berries in the husk, of *Coccus Indicus*, and the berries passed through the body of the child without doing any injury. It was submitted for the prisoner, that being in the husk they could not be considered a poison. The point was reserved by Mr. Justice Williams, who tried the case at York. It was now contended for the prisoner, that although the kernel of this nut was poisonous, still having been given in the husk, which was hard of digestion, it could not be considered an administering of poison within the statute 1 Vict. c. 85. The Chief-Justice said the Court was of opinion that, where a man administered something that was poison with intent to murder, but in such a way that it did not act, he was guilty. Conviction affirmed. This is the only reasonable view to take of such an objection. The seed contains the poison, but the husk is inert: nevertheless the berry must be regarded as a poison.
DEADLY POISON. — MECHANICAL IRRITANTS.

Deadly poison.—There is another point of view in which this question may require to be considered — namely, What is to be understood by a deadly poison? In indictments for poisoning, it is customary to describe every poison as deadly,—a form of expression decidedly bad and calculated to give rise to technical objections. The substance administered might with equal propriety be described as poisonous, or of a destructive nature: but those who draw up indictments are but little informed on such matters, and they can rarely speak of a poison without describing it as deadly. This term can, however, be applied with propriety only to those poisons which may prove speedily fatal in small doses — e. g., prussic acid, arsenic, strychnia, aconitina, and nicotina; and although it has been used in indictments in reference to such substances as blue or green vitriol, and common sal volatile, this has arisen from an unnecessarily strict adherence to old legal forms. In a case (Reg. v. Hayden, Somerset Spring Assizes, 1845), in which "spirit of hartshorn" was thus described as a "deadly poison," and an objection was taken to the validity of the indictment, the learned judge (Erle J.) held that the word deadly was not essential: it was mere surplusage (Law Times, April 12, 1845). This decision is in accordance with common sense.

Mechanical irritants.—Such, then, is the present state of the law of England in respect to administering or attempting to administer poison with intent to murder, altogether irrespective of the act being followed by fatal consequences. While the words of the statute render it unnecessary for a medical witness, in these cases, to give judicially a very close definition of a "poison," they impose upon him a difficulty which he must be prepared to meet. The substance administered may not be a poison in the medical signification of the term, and it may not be popularly considered as such; yet, when taken, it may be destructive to life. We have examples of substances of this description in iron-filings, powdered glass, sponge, pins and needles, and such like bodies, all of which have been administered with the wilful design of injuring, and have on various occasions given rise to criminal charges. In cases of this kind, the legal guilt of a prisoner may often depend on the meaning assigned by a medical witness to the words destructive thing. Thus, to take an example, liquid mercury might be poured down the throat of an infant, with the deliberate attempt to destroy it. A question of a purely medical nature will then arise whether mercury be "a destructive thing" or not; and the conviction of a prisoner will probably depend on the answer returned by the witnesses. Should a difference of opinion exist,—an occurrence by no means unusual in medical evidence,—the prisoner will, according to the humane principle of our law, receive the benefit of the doubt.
Among the singular methods resorted to for the purpose of destroying the lives of infants and children, that of causing them to swallow pins or needles in their food is one which claims the attention of medical jurists. This mode of attempting murder has been brought to light by the evidence given on several criminal trials, which have taken place of late years in England and on the continent. In cases of this description, death is commonly to be referred to inflammation; and a practitioner can have no hesitation in designating these substances, when exhibited to infants, as "destructive things." They are at all times likely to lead to serious injury if not to death; and it is no answer to this view to assert, that they have been often swallowed with impunity. We know that active poisons are sometimes taken without causing death: but this does not alter our opinion, that they are substances destructive to life, and likely to give rise to the most serious consequences.

Influence of Habit on Poisons.—Habit, it is well known, diminishes the effect of certain poisons: thus it is that opium, when frequently taken by a person, loses its effect after a time, and requires to be administered in a much larger dose. Indeed, confirmed opium-eaters have been enabled to take at once, a quantity of the drug which would have infallibly killed them, had they commenced with it in the first instance. Even infants and young children, who are well known to be especially susceptible of the effects of opium, and are liable to be poisoned by very small doses, may, by the influence of habit, be brought to take the drug in very large quantities. This is well illustrated by a statement made by Mr. Grainger, in the Report of the Children's Employment Commission. It appears that the system of drugging children with opium in the Factory districts, commences as soon after birth as possible; and the dose is gradually increased until the child takes from fifteen to twenty drops of laudanum at once! This has the effect of throwing it into a lethargic stupor. Healthy children of the same age would be killed by a dose of five drops. The same influence of habit is manifested more or less in the use of tobacco, alcohol, ether, chloroform, strychnia, and other alkaloids. Dr. Christison has remarked that this influence is chiefly confined to poisons derived from the organic kingdom: and I quite agree with him, in thinking that the stories related of the arsenic-eaters of Styria, and the corrosive sublimate-eaters of Turkey are not to be credited. There is no satisfactory proof that any human being has ever accustomed himself, by habit, to take these substances in doses that would prove poisonous to the generality of adults. I have only met with one fact which appears adverse to this opinion. M. Flandin states that he gave to animals doses of arsenious acid in powder, commencing with 1/65th of a grain mixed with their food; and that in nine months, by progressive increase, they bore a dose of upwards of fifteen grains of arsenious acid in pow-
Influence of Idiosyncrasy.

Idiosyncrasy differs from habit:—it does not, like habit, diminish the effect of a poison; for it is not commonly found that any particular state of body is a safeguard against the effects of these powerful agents. Some constitutions are observed to be much more affected than others by certain poisons:—thus opium, arsenic, mercury and antimony are substances of this description, and this difference in their effects is ascribed to idiosyncrasy. Dr. Christison mentions a remarkable instance, in which a gentleman unaccustomed to the use of opium, took nearly an ounce of good landanum without any effect. (On Poisoning, 83.) This form of idiosyncrasy is very rare. Certain substances generally reputed harmless, and, indeed, used as articles of food, are observed to affect some persons like poisons. This is the case with pork, certain kinds of shell-fish, and mushrooms. There may be nothing poisonous in the food itself; but it acts as a poison in particular constitutions;—whether from its being in these cases a poison per se, or rendered so by changes during the process of digestion, it is difficult to say. The subject of idiosyncrasy is of great importance in a medico-legal view when symptoms resembling those of poisoning follow a meal consisting of a particular kind of food. In such a case, without a knowledge of this peculiar condition, we might hastily attribute to poison, effects which were really due to another cause. It would appear that in some instances idiosyncrasy may be acquired—i.e., a person who, at one period of his life, had been in the habit of partaking of a particular kind of food without injury, may find at another period that it will disagree with him. When pork has been disused as an article of diet for many years, it cannot always be resumed by individuals with impunity.
In cases in which the powers of life have become enfeebled by age, the susceptibility of the system to poisons is increased; thus aged persons may be killed by comparatively small doses of arsenic and opium. Cases of acquired idiosyncrasy are very rare; it appears to be, if we may so apply the term, a congenital condition. There are, however, certain diseases, which appear to confer a power of supporting large and even poisonous doses of some substances. Very large doses of opium have been taken without producing dangerous symptoms by persons labouring under tetanus and hydrophobia. This condition is called tolerance. It is witnessed in diseases of the lungs in reference to antimonial medicines. (See page 12, post.)

Classification of Poisons.—Poisons have been divided into three classes, according to their mode of action on the system; namely, Irritants, Narcotics, and Narcotic-Irritants. This classification is a modification of that originally proposed by Orfila.

The Narcotics and Narcotic-irritants may, however, be regarded as constituting one large class, the Neurotics, as their special action is to affect directly one or more parts of the nervous system. The narcotic poisons admit of a subdivision into Cerebral, Spinal, and Cerebro-spinal, according to whether the poisonous substance affects directly the brain, the spinal marrow, or both of these organs.

Irritants.—The irritants are possessed of these common characters. When taken in ordinary doses, they occasion speedily violent vomiting and purging. These symptoms are either accompanied or followed by intense pain in the abdomen. The peculiar effects of the poison are manifested chiefly on the stomach and intestines, which, as their name implies, they irritate and inflame. Many substances belonging to this class of poisons possess corrosive properties; such as the strong mineral acids, caustic alkalies, bromine, corrosive sublimate, and others. These, in the act of swallowing, are commonly accompanied by an acrid or burning taste, extending from the mouth down the esophagus to the stomach. Some irritants do not possess any corrosive action,—of which we have examples in arsenic, the poisonous salts of baryta, carbonate of lead, caustharides, &c., and these are often called pure irritants. They exert no destructive chemical actions on the tissues with which they come in contact; they simply irritate them.

Difference between Corrosive and Irritant Poisons.—There is this difference between Corrosive and Irritant poisons. Under the action of corrosive poisons the symptoms are commonly manifested immediately, because mere contact produces disorganisation of a part, usually indicated by some well-marked symptoms. In the action of the purely irritant poisons, the symptoms are generally more slowly manifested, rarely showing
CORROSIVE, IRRITANT, AND NEUROTIC POISONS.

themselves until at least half an hour has elapsed from the time of swallowing the substance. Of course, there are exceptions to this remark; for sometimes irritants act speedily, though seldom with the rapidity of corrosive poisons. It is important, in a practical view, to distinguish whether, in an unknown case, the poison which a person, requiring immediate treatment, may have swallowed, be irritant or corrosive. This may be commonly determined by the answer to the question, as to the time at which the symptoms appeared after the suspected poison was taken. In this way we may often easily distinguish between a case of poisoning from arsenic and one from corrosive sublimate. There is also another point which may be noticed. As the corrosive is due to a decided chemical action, so the examination of the mouth and fauces may enable us in some cases to determine the nature of the poison swallowed.

It has been already stated that there are many irritant poisons which have no corrosive properties, and therefore never act as corrosives; but it must be remembered that every corrosive may act as an irritant. Thus the action of corrosive sublimate is that of an irritant poison, as, while it destroys some parts of the coats of the stomach and intestines, it irritates and inflames others. So again most corrosive poisons may lose their corrosive properties by dilution with water, and then they act simply as irritants. This is the case with the mineral acids, and bromine. In some instances, it is not easy to say whether an irritant poison possesses corrosive properties or not. Thus oxalic acid acts immediately, and blanches and softens the mucous membrane of the mouth and fauces, but I have not met with any decided marks of what could be called chemical corrosion produced by it in the stomach or viscera. Irritant poisons, for the most part, belong to the mineral kingdom; and they may be divided into the Non-metallic and Metallic irritants. There are a few derived from the animal and vegetable kingdom; but these are not often employed criminally. Some of the gases likewise belong to the class of irritant poisons.

Neurotics.—Neurotic poisons have their operation confined chiefly to the brain and spinal marrow. Either immediately or some time after the poison has been swallowed, the patient suffers from headache, giddiness, paralysis, stupor, and in some instances convulsions. They have no acrid burning taste like the corrosive irritants; and they very rarely give rise to vomiting or purging. When these symptoms follow the ingestion of the poison into the stomach, the effect may be generally ascribed either to the form or quantity in which the poison has been taken, and the mechanical effect on the stomach thereby produced, or to the poison being combined with some irritating substance, such as alcohol. The pure narcotics, or Cerebral poisons, are not found to irritate or inflame the stomach and bowels.
Notwithstanding the well-defined boundary thus apparently existing between these two classes of poisons, it must not be supposed that each class of bodies always act in the manner indicated. Some irritants have been observed to affect the brain or the spinal marrow remotely, and either as a primary or secondary consequence of their action. This is the case with oxalic acid and arsenic. Both of these common poisons have in some instances given rise to symptoms closely resembling those of narcotic poisoning; namely, coma, paralysis, and tetanic convulsions. In a case of poisoning by arsenic, which occurred to Dr. Morehead, of Bombay, the symptoms of narcotism were so strongly marked, that it was believed at first that the man had taken a narcotic. (Med. Gaz. vol. xliii. p. 1055.) I have met with a case of poisoning by arsenic in which there was paralysis of the limbs, with an entire absence of purging, during the eight days that the deceased survived. On the other hand, in the chapter on opium, a case of poisoning by a large dose of this drug will be found related, in which there was an absence of the usual symptoms of cerebral disturbance, and the presence of others resembling those of irritant poisoning—namely, pain and vomiting. Thus, then, we must not allow ourselves to be misled by the idea that the symptoms are always clearly indicative of the kind of poison taken. The narcotic or cerebral poisons are few in number, and belong to the vegetable kingdom. Some of the poisonous gases possess a narcotic action.

Narcotic-Irritants. (Spinal and Cerebro-spinal Poisons.)—Poisons belonging to this class have, as the name implies, a compound action. They are chiefly derived from the vegetable kingdom. At variable periods after they have been swallowed they give rise to vomiting and purging, like irritants; and sooner or later produce stupor, coma, paralysis and convulsions, owing to their effects on the brain and spinal marrow. They possess the property, like irritants, of irritating and inflaming the alimentary canal. As familiar examples we may point to nux vomica, monkshood, and poisonous mushrooms. This class of poisons is very numerous, embracing a large variety of well-known vegetable substances; but they rarely form a subject of difficulty to a medical practitioner. The fact of the symptoms occurring after a meal at which some suspicious vegetables may have been eaten, coupled with the nature of the symptoms themselves, will commonly indicate the class to which the poison belongs. Some of these poisons have a hot acrid taste, such as theaconite or monkshood; others, an intensely bitter taste, as nux vomica and its alkaloid strychnia. Strychnia may be regarded as a pure spinal poison.
CHAPTER II.

EVIDENCE OF POISONING IN THE LIVING SUBJECT—SYMPTOMS OCCUR SUDDENLY—MODIFYING CONDITIONS—ACTION OF POISONS INCREASED OR DIMINISHED BY DISEASE—SYMPTOMS CONNECTED WITH FOOD OR MEDICINE—SUDDEN DEATH FROM NATURAL CAUSES MISTAKEN FOR POISONING—SEVERAL PERSONS ATTACKED SIMULTANEOUSLY—EVIDENCE FROM THE DETECTION OF POISON IN THE FOOD.

We now proceed to consider the evidence of poisoning in the living subject. To the practitioner the diagnosis of a case of poisoning is of great importance, as by mistaking the symptoms produced by a poison for those arising from natural disease, he may omit to employ the remedial measures which have been found efficacious in counteracting its effects, and thus lead to the certain death of the patient. To a medical jurist a correct knowledge of the symptoms furnishes the chief evidence of poisoning, in those cases in which persons are charged with the criminal administration of poison with intent to murder, but from the effects of which the patient ultimately recovers. The symptoms produced during life, constitute also an important part of the evidence in those instances in which the poison proves fatal. At present, however, we will suppose the case to have been, that poison has been taken and the patient survives. Most toxicological writers have laid down certain characters whereby it is said symptoms of poisoning may be distinguished from those of disease.

1. In poisoning, the symptoms appear suddenly, while the individual is in health.—It is the common character of most poisons, when taken in the large doses in which they are usually administered with criminal intent, to produce serious symptoms either immediately or within a very short period after they have been swallowed. Their operation, under such circumstances, cannot be suspended, and then manifest itself after an indefinite interval; although this was formerly a matter of universal belief, and gave rise to many absurd accounts of what was termed slow poisoning.

The symptoms of poisoning by prussic acid, oxalic acid, or the salts of strychnia, appear immediately, or generally within a very few minutes after the poison has been swallowed. In one case, in which the dose of prussic acid was small, and insufficient to produce death, the poison was supposed by the patient not to have begun to act until after the lapse of fifteen minutes. (Ed. Med. and Surg. Journ. lix. 72.) The symptoms caused by arsenic and other irritants, and, indeed, by all poisons
generally, are commonly manifested in from half an hour to an hour. It is rare that the appearance of the symptoms is protracted for two hours, except under certain peculiar states of the system. It is said, that some neurotic poisons, such as the poisonous mushrooms, may remain in the stomach twelve or twenty-four hours without giving rise to symptoms; and this is also affirmed to be the case with some animal irritants, such as decayed meat; but with regard to the first point, it has been shown by Dr. Peddie, that mushrooms have produced symptoms in half an hour; and a case has fallen under my own observation, in which the symptoms from noxious animal food came on within as short a time after the meal, as is commonly observed in irritant poisoning by mineral substances. In cases of poisoning by phosphorus, the symptoms do not commonly begin until after the lapse of some hours.

Modifying conditions. Influence of disease.—A diseased state of the body may render a person comparatively unsusceptible of the action of some poisons, while in other instances it may increase their action, and render them fatal in small doses. In dysentery and tetanus, a person will take, without being materially affected, a quantity of opium sufficient to kill an adult in average health. Mania, cholera, hysteria, and delirium tremens, are also diseases in which large doses of opium may be borne with comparative impunity. In a case of hemiplegia, a woman aged 29, took for six days, three grains of strychnia daily without injurious consequences—the dose having been gradually raised (Gaz. Med. Mâl 1845); while one grain of strychnia is commonly regarded as a fatal dose to a healthy person. In a case of tetanus, Dupuytren gave as much as two ounces of opium at a dose (60 grammes), without serious consequences. (Flandin, Traité des Poisons, i. 231.) It has also been remarked, that persons affected with tetanus are not easily salivated by mercury. The morbid state appears to create the power of resisting the ordinary effects of poisons. (Colles's Lectures, i. 77.) The effect of certain diseases of the nervous system as well as of habit, either in retarding the appearance of symptoms, or in blunting the operation of a poison, it is not difficult to appreciate; they are cases which can present no practical difficulty to a medical juris. On the other hand, in certain diseased states of the system, there is an increased susceptibility of the action of poison. Thus, in those persons who have a disposition to apoplexy, a small dose of opium may act more quickly and prove fatal. In a person labouring under inflammation of the stomach or bowels, there would be an increased susceptibility of the action of arsenic or other irritants. One of the most remarkable instances of the influence of disease in increasing the operation of poison, is perhaps seen in cases of diseased kidney (granular degeneration) in which very small doses of mercury have been observed to
produce severe salivation, leading to exhaustion and death. A knowledge of this fact is of importance in reference to charges of malappraxis, when death has arisen from ordinary doses of opium administered to persons labouring under this disease.

Symptoms appear during a state of Health.—Symptoms of poisoning often manifest themselves in a person while in a state of perfect health, without any apparent cause. This rule is of course open to numerous exceptions, because the person on whose life the attempt is made, may be actually labouring under disease; and under these circumstances, the symptoms of poisoning are so obscure as often to disarm all suspicion. When poison is exhibited in medicine, a practitioner is very liable to be deceived, especially if the disease under which the party is labouring be of an acute nature, and attended by symptoms of disorder in the alimentary canal. Several cases of poisoning have occurred within the last few years, in which arsenic was criminally substituted for medicine, and given to the parties while labouring under a disorder of the bowels. We are, however, justified in saying with respect to this character of poisoning, that when in a previously healthy person, violent vomiting and purging occur suddenly and without any assignable cause, such as disease, or indiscretion in diet, to account for them, there is strong reason to suspect that irritant poison has been taken. When the person is already labouring under disease, we must be especially watchful, on the occurrence of any sudden change in the character or violence of the symptoms, unless such change can be easily accounted for on common or well-known medical principles. In most cases of criminal poisoning, we meet with alarming symptoms without any obvious or sufficient natural causes to explain them. The practitioner will of course be aware that there are certain diseases which are liable to occur suddenly in healthy people, the exact cause of which may not at first sight be apparent; therefore this criterion is only one out of many on which a medical opinion should be founded.

2. In poisoning, the symptoms appear soon after a meal, or soon after some kind of food or medicine has been taken.—This is by far the most important character of poisoning in the living body. It has been already stated, that most poisons begin to act within about an hour after they have been swallowed; and although there are a few exceptions to this remark, yet they occur under circumstances easily to be appreciated by a practitioner. Thus, then, it follows, that, supposing the symptoms under which a person is labouring to depend on poison, the substance has most probably been swallowed either in food or medicine, from half an hour to an hour previously. It must be observed, however, that cases of poisoning may occur without the poison being introduced by the mouth. Oil of vitriol has been thrown up the rectum in the form of enema, and caused
death: the external application of arsenic, corrosive sublimate, and cantharides, has destroyed life. In one case arsenic was introduced into the vagina of a female, and she died in five days under all the symptoms of arsenical poisoning. (Schneider, Ann. der ges. Staatsarzneikunde, i. 229.) Such cases are rare, but nevertheless the certainty that they have occurred where their occurrence could hardly have been anticipated, shows that in a suspicious case, a practitioner should not deny the fact of poisoning, merely because it is proved that the patient could not have taken the poison in the usual way—by deglutition. Again, persons may be destroyed by the vapours of ether, chloroform, prussic acid, or other powerful volatile poisons, introduced into the system through the lungs. Such a mode of suicide, or murder, might disarm suspicion, from the fact of no noxious material being found in the stomach. An Act of Parliament has been passed, which makes it felony to administer, or even to attempt to administer, poisons in this manner (14 and 15 Vict. c. 19, sec. 111).

Let us suppose, however, the circumstances to have been such that these secret means of destruction could not have been resorted to, and that the poison is one of those most commonly selected by a murderer, such as arsenic, oxalic acid, or corrosive sublimate, then we may expect that this character of poisoning will be made evident to us, and that something must have been swallowed by the patient shortly before the alarming symptoms appeared. By observations attentively made, it may be in our power to connect the appearance of the symptoms with the use of a particular article of food, and thus indirectly lead to the detection of the criminal. Supposing that many hours have passed since food or medicine was taken by the patient, without any effect ensuing,—it is probable that the symptoms may be due to some other cause, and not to poison. The time of the occurrence of symptoms in relation to a particular meal, is then a fact of especial importance in forming an opinion when poisoning is suspected.

Among the numerous cases which might be adduced in support of this statement, the following may be selected: it was communicated by Mr. George, of Bath, to the Provincial Journal (January 24th, 1849):—The patient, a girl aged 16, was pregnant; she complained of a painful swelling of the leg. On the day of her death she made a hearty dinner of beef, vegetables, and porter, with the family at one o'clock, and remained in the same room where she had partaken of that meal until three o'clock. On quitting the apartment, she began to groan, complained of agony at the pit of the stomach, and became faint: there was vomiting, and in three-quarters of an hour she died. On inspection, there was an inflamed appearance both of the duodenum and stomach. A careful analysis of the visera, as well as of the matter vomited, revealed no poison; and the fact that no symptoms had occurred, during
a period of two hours after the meal, strongly corroborated the conclusion that the deceased had died from natural causes.

When symptoms resembling those of poisoning speedily follow the ingestion of food or medicine, there is, however, always great room for suspicion; but caution should be observed in drawing inferences, since the most extraordinary coincidences sometimes present themselves. In the celebrated case of Sir Theodosius Boughton, who was poisoned by his brother-in-law, Donellan, in 1781, the fact of alarming symptoms coming on in two minutes after the deceased had swallowed what was supposed to be a simple medicinal draught, was a most important fact in the evidence against the prisoner. There is no doubt that laurel-water had been substituted for the medicine by the prisoner. I may here remark, that the practice of substituting poisonous mixtures for medicinal draughts or powders is by no means unusual; although it might be supposed to indicate a degree of refinement and knowledge not commonly to be found among the lower class of criminals. Medical practitioners are thus apt to be imposed upon, and the following case, related by a lately deceased judge, will serve as a caution. An apothecary prepared a draught, into which another person put poison, intending thereby to destroy the life of the patient for whom the medicine was prescribed. The patient, not liking the taste of the draught, and thinking there was something suspicious about it, sent it back to the apothecary, who, knowing the ingredients of which he had composed it, and wishing to prove to his patient that he had done nothing wrong, drank it himself, and died. He was thus the unconscious agent of his own death; and although the draught was intended for another, the party who poisoned it was held guilty of murder. This case contains a serious warning to medical witnesses. It is not unusual, on trials for poisoning, when the poison is conveyed through medicine, to find a medical witness offering to swallow his own draught in a Court of Law, in order to furnish to the Court and jury a convincing practical illustration of the innocence of the medicine! It need hardly be observed that an exhibition of this kind is never required of a medical witness. The Court will receive his deposition, without compelling him to swallow his own medicine, even supposing that it has not been secretly poisoned. If any doubt be raised of the innocent properties of a draught or powder, a chemical analysis of its contents will be far more satisfactory, and attended with no kind of risk to the practitioner.

On the other hand, the occurrence of symptoms resembling those produced by poisoning, soon after food or medicine has been taken, may be a pure coincidence. In such a case, poison is always suspected by the vulgar; and it will be the duty of a medical jurist to guard against the encouragement of such a suspicion, until he has strong grounds to believe it to be well founded. No public retraction or apology can ever make amends for the injury which
may in this way be inflicted on the reputation of another; for they who hear the accusation, may never hear the defence. In all such cases, a practitioner may entertain a suspicion, but he should always avoid expressing it, or giving it publicity. When death is not a consequence, it is difficult to clear up such cases, except by the aid of a chemical analysis; but this, as we know, is not always applicable. If death ensue, the real cause is usually apparent, and a suspicion of poisoning is thus often removed by an examination of the body.

3. In poisoning, when several partake at the same time of the same food or medicine (mixed with poison) all suffer from similar symptoms.—This character of poisoning cannot always be procured; but it furnishes good evidence of the fact when it exists. Thus, supposing that after a meal made by several persons from the same dish, only one suffers, the suspicion of poisoning is considerably weakened. The poisoned article of food may be detected by observing whether they who suffer under any symptom of poisoning, have partaken of one particular solid or liquid in common. In a case of accidental poisoning at a dinner-party, a medical man who was present observed that those who suffered had taken port wine only: the contents of the bottle were examined, and found to be a saturated solution of arsenic in wine. In general considerable reliance may be placed upon this character, because it is very improbable that any common cause of disease should suddenly attack with violent and alarming symptoms many healthy persons at the same time, and within a short period after having partaken of food together. We must beware of supposing that, in those cases in which poison is really present, all will be attacked with precisely similar symptoms; because, as we have seen, there are many circumstances which may modify their nature and progress. In general that person who has partaken most freely of the poisoned dish will suffer most severely; but even this does not always follow. There is a well-known case, recorded by Bonnet, where, among several persons who partook of a dish poisoned with arsenic, they who had eaten little and did not vomit speedily died; while others who had partaken largely of the dish, and had in consequence vomited freely, recovered.

It was just now remarked, that there is no disease likely to attack several healthy persons at the same time, and in the same manner. This is undoubtedly true, as a general principle, but the following case will show that mistakes may occasionally arise even under these circumstances. It occurred in London, during the prevalence of the malignant cholera in the year 1832. Four of the members of a family, living in a state of great domestic unhappiness, sat down to dinner in apparently good health: some time after the meal, the father, mother, and daughter, were suddenly seized with violent vomiting and purging. The stools were tinged with blood, while the blueness of the skin, observed
in cases of malignant cholera, was wanting. Two of the parties died. The son, who was known to have borne ill-will against his father and mother, and who suffered no symptoms on this occasion, was accused of having poisoned them. A strict investigation took place before the coroner; but it was clearly shown by the medical attendant, that the deceased persons had really died of the malignant cholera, and there was no reason whatever to suspect that any poison had been administered to them. In this instance it will be perceived that symptoms resembling those of irritant poison appeared suddenly in several individuals in perfect health, and shortly after a meal. We hereby learn that the utility of any rules for investigating cases of poisoning depends entirely on the judgment and discretion with which they are applied to particular cases.

It is well to bear in mind, in conducting these inquiries, that symptoms resembling those produced by irritant poison may be sometimes due to the description of food which may have been taken at the meal. Besides flesh rendered unwholesome from disease and decay, there are certain kinds of shell-fish, as well as pork, bacon, sausages, cheese, and bread, which, under certain circumstances, may give rise to formidable symptoms, and even death. In such a case, all the foregoing characters of poisoning are brought out; and, indeed, the case may be regarded as one of poisoning by an animal or vegetable irritant. The diagnosis is difficult; and great ambiguity frequently arises from the fact that not more than one or two individuals may be affected, who have on previous occasions partaken of the same kind of food without any inconvenience.

4. The discovery of poison in the food taken, or in the matters vomited. — One of the best proofs of poisoning in the living subject, is the detection of poison by chemical analysis, or, if of a vegetable nature, by a microscopical examination, either in the food taken by the person labouring under its effects, or in the matters vomited. The evidence is of course more satisfactory when the poison is detected in the matters vomited, than in the food; because this will show that the poison has really been taken, and will readily account for the symptoms. If the vomited matters have been thrown away, we must then examine the food of which the patient may have partaken. Should the results in both cases be negative, and no trace of poison be found in the urine, the probability is, that the symptoms may have been due to disease.

In investigating a case of poisoning in the living subject, a medical jurispr launch must remember, that poisoning is sometimes feigned and at others, imputed. It is very easy for an artful person to put poison into food, as well as to introduce it into the matters vomited or discharged from the bowels, and to accuse another of having administered it. There are few of these accusers who go so far as to swallow poison under such circumstances, as there is a great
dread of poisonous substances among this class of criminals; and it will be at once apparent, that it would require a person well versed in toxicology, to feign a series of symptoms which would impose upon a practitioner at all acquainted with the subject. In short, the difficulty reduces itself to this:—What inference can we draw from the chemical detection of poison in food? All that a medical man can do, is to say whether poison be present or not in a particular article of food;—he must leave it to the authorities of the law to develop the alleged attempt at administration;—but if the poison have been actually administered or taken, then we should expect to find the usual symptoms. The absence of these symptoms would be a strong fact against the alleged administration. With regard to the detection of poison in the matters vomited from the stomach, this affords no decisive proof that it has been swallowed, except under two circumstances:—1. When the accuser has really laboured under the usual symptoms of poisoning, in which case there can be no feigning, and the question of imputation is a matter to be established by general evidence. 2. When the matters are actually vomited into a clean vessel in the presence of the medical attendant himself, or of some person on whose testimony perfect reliance can be placed.

CHAPTER III.

ON THE EVIDENCE OF POISONING IN THE DEAD BODY—PERIOD AT WHICH POISONS PROVE FATAL—CHRONIC POISONING—APPEARANCES PRODUCED BY THE DIFFERENT CLASSES OF POISONS—REDNESS OF THE MUCOUS MEMBRANE MISTAKEN FOR INFLAMMATION—ULCERATION AND CORROSION—SOFTENING—PERFORATIONS OF THE STOMACH FROM POISON AND DISEASE.

Supposing that the person is dead, and we are required to determine whether the case be one of poisoning or not, we must, in the first instance, endeavour to ascertain all the particulars which have been discussed in the last chapter, as indicating poisoning in the living subject. Should the deceased have died from poison, the circumstances of the attack, and the symptoms preceding death, ought to correspond with the characters already described; and in these investigations it is well to bear in mind the following rule;—There is no one symptom or pathological condition which is peculiar to poisoning; but at the same time there is no disease which presents all those characters which are met with in a special case of poisoning. The additional evidence to be derived from
the death of the person, may be considered under the following heads:—

1. The time at which death takes place after the first occurrence of symptoms.—This question it is necessary to examine, because the more common poisons, when taken in fatal doses, generally produce their fatal effects within certain periods of time. By an attention to this point, we may, in some instances, be enabled to negative a charge of poisoning, and in others to form an opinion of the kind of poison which has been taken. In a Court of law, a medical practitioner is often required to state the usual period of time within which poisons prove fatal. It is to be observed, that not only do poisons differ from each other in this respect, but the same substance, according to the form or quantity in which it has been taken, will differ in the rapidity of its action. A large dose of prussic acid, i.e. from half an ounce to an ounce, may destroy life in less than two minutes. In ordinary cases of poisoning by this substance, a person dies, i.e. all signs of life have commonly ceased, in from ten to twenty minutes:—if he survive half an hour, there is some hope of recovery. In the cases of the seven Parisian epileptics, accidentally poisoned by this acid, the first died in about twenty minutes, the seventh survived three quarters of an hour. Oxalite, one of the most energetic of the common poisons, when taken in a dose of from half an ounce to an ounce, may destroy life in from ten minutes to an hour: if the poison be not perfectly dissolved when swallowed, it is a longer time in proving fatal. The strong mineral acids, in poisonous doses, destroy life in about eighteen or twenty-four hours. Arsenic, under the form of arsenious acid (white arsenic), operates fatally in from eighteen hours to three or four days. It has, however, in more than one instance killed a person in two hours; although this is by no means common. Opium, either as a solid or under the form of laudanum, commonly proves fatal in from six to twelve hours; but it has been known, in several instances, to destroy life in less than three hours: they who survive the effects of this poison for twelve hours, are considered to have a fair chance of recovery. This must be understood to be merely a statement of the average results, as nearly, perhaps, as we are warranted in giving an opinion; but the medical jurisprudent will of course be aware, that the fatal period may be protracted or shortened, according to all those circumstances which have been elsewhere stated to affect the action of poisons.

There are various forms which this question may assume in a Court of law:—the death of a party, alleged to have taken poison, may have occurred too rapidly or too slowly to justify a suspicion of poisoning. The following case may serve as an illustration:—A woman of the name of Russell was tried and convicted at the Lewes Summer Assizes, in 1826, for the murder of her husband, by poisoning him with arsenic. The poison was
detected in the stomach; but the fact of poisoning was disputed by some medical witnesses, for this among other reasons—that the deceased had died three hours after the only meal at which the poison could have been administered to him. The authority of Sir A. Cooper and others, was cited to show, that, according to their experience, they had never known a case to prove fatal in less than seven hours. This may have been; but, at the same time, there was sufficient authority on the other side, to establish that some cases of arsenical poisoning had actually proved fatal in three or four hours. So far as this objection was concerned, the prisoner was very properly convicted. In reference to the medical question raised at this trial, I may observe, that within the last few years, two distinct cases have occurred in which the individuals died certainly within two hours after taking arsenic; and several instances have been reported since the trial, in which death took place in from three to four hours after the administration of this poison. It seems extraordinary in the present day, that any attempt should have been made by a professional man to negative a charge of criminal poisoning upon so weak a ground as this; but we must remember, that this opinion was expressed many years ago, when the subject of toxicology was but little understood. It is quite obvious, that there is nothing, so far as we know, to prevent arsenic from destroying life in an hour. A case will be hereafter related, in which death took place from arsenic most probably in half an hour. These matters can be settled only by a careful observation of numerous cases, and not by any a priori reasoning, or reference to individual experience.

In all instances of sudden death, there is generally a strong tendency on the part of the vulgar to suspect poisoning. They never can be brought to consider, that persons may die a natural death suddenly, as well as slowly; or, as we shall presently see, that death may really take place slowly, as in cases of disease, and yet be due to poison. This prejudice continually gives rise to the most unfounded suspicions of poisoning. One of the means recommended for distinguishing narcotic poisoning from apoplexy or disease of the heart, is the difference in the rapidity with which death takes place. Thus, apoplexy or disease of the heart may prove fatal either instantly, or within an hour. The only common poison likely to operate with such rapidity is prussic acid. Poisoning by opium is commonly protracted for five or six hours. This poison has never been known to destroy life instantaneously, or in a few minutes. Thus, then, it may happen, that death will occur with such rapidity, as to render it impossible under the circumstances to attribute it to narcotic poison.

Chronic poisoning.—When a poison destroys life rapidly, it is called a case of acute poisoning, to distinguish it from the chronic form, i.e. in which death takes place slowly. Chronic poisoning
is not a subject which often requires medico-legal investigation. Most poisons, when their effects are not rapidly manifested, owing either to the smallness of the dose or to timely treatment, are capable of slowly undermining the powers of life, and killing the patient by producing emaciation and exhaustion. This is sometimes observed in the action of arsenic, corrosive sublimate, and tartarized antimony, but it has been remarked also in cases of poisoning by the mineral acids and caustic alkalies. Death is here an indirect consequence;—in poisoning by the acids or alkalies, either stricture of the oesophagus is induced, or the lining membrane of the stomach is destroyed, and the process of digestion impaited,—a condition which leads to emaciation and death. The time at which these indirect efforts may prove fatal, is of course liable to vary. A person has been known to die from a stricture of the oesophagus brought on by sulphuric acid, eleven months after the poison was swallowed; and there is no reason to doubt that instances may occur of a still more protracted nature. In these cases of chronic poisoning, there is considerable difficulty in assigning death exclusively to the original action of the poison, since the habits of life of the party,—a tendency to disease, and other circumstances, may have concurred either to accelerate, or produce a fatal result. To connect a stricture of the oesophagus with the act of poisoning by a mineral acid, it is necessary to show that there was no tendency to this disease before the acid was administered:—that the symptoms appeared soon after the first effects of the poison went off:—that these symptoms continued to become aggravated until the time of death—and that there was no other cause, to which death could with any probability be referred. These remarks apply equally to the indirectly fatal effects of any poison,—such, for instance, as the salivation occasionally induced by corrosive sublimate, and the exhaustion and depression produced by tartarized antimony, when the acute symptoms of poisoning by these substances have passed away. It has been stated, that chronic poisoning is not a subject commonly requiring a criminal investigation. Several cases have, however, come before our tribunals, in which the facts connected with this form of poisoning were of some importance. I allude to those of Miss Blandy, tried at Oxford, in 1752, for the murder of her father by arsenic; and of a woman named Butterfield, tried at Croydon, in 1775, for the murder of a Mr. Scawen, by administering corrosive sublimate. Among cases of recent occurrence may be mentioned that of Mrs. Wooler (Reg. v. Wooler, Durham Winter Assizes, 1855), in which it was proved that the deceased had been under the influence of arsenic, administered at intervals in repeated doses, for a period of about seven weeks before her death. She died from exhaustion and the secondary effects of the poison. In three other cases tartarized antimony was the poison selected. It was given in repeated doses, over
different periods, and caused death, by the specific effects of poisoning in a chronic form. 1. The case of Ann Palmer (Guy’s Hospital Reports, October, 1857). 2. The case of McMullen (Liverpool Summer Assizes, 1856), in which a woman was tried and convicted for causing the death of her husband; and 3rd, the case of Reg. v. Hardman (Lancaster Summer Assizes, 1857), in which a man was convicted of the murder of his wife. In most cases, murderers destroy life by administering poison in very large doses; but in the instances referred to, small doses were given at intervals,—a fact which, in some of them, led to a medical doubt of the real cause of the symptoms.

2. Evidence from appearances in the body.—One of the chief means of determining whether a person has died from poison, is an examination of the body after death. In relation to external appearances, there are none indicative of poisoning upon which we can safely rely. It was formerly supposed that the bodies of persons who were poisoned, putrefied more rapidly than those of others who had died from natural disease; and evidence for or against poisoning was at one time derived from the external appearance of the body. This is now known to be an error: the bodies of persons poisoned are not more rapidly decomposed, ceteris paribus, than those of others who have died a sudden and violent death from any other cause whatever.

Irritant poisons act chiefly upon the stomach and intestines, which they irritate, inflame, and corrode. We may likewise meet with all the consequences of inflammation, such as ulceration, perforation, and gangrene. Sometimes the coats of the viscera are thickened, at other times thinned and softened, by the action of an irritant.

Neurotic (Cerebral and Spinal) poisons do not commonly leave any well-marked appearances in the body. The stomach and intestines present no unnatural changes. There is greater or less fulness of the cerebral vessels; but even this is often so slight as to escape notice, unless attention be particularly directed to the brain. Effusion of blood is rarely found.

The Narcotic-irritants or Cerebro-spinal poisons affect either the brain or the alimentary canal, and commonly both, according to their peculiar mode of action.

It is important to bear in mind, that both Irritants and Neurotics may destroy life without leaving any appreciable changes in the body. To such cases as these, the remarks about to be made do not apply. The proofs of poisoning must, then, be procured entirely from other sources. Any evidence derivable from the appearances in the body of a person poisoned, will be imperfect unless we are able to distinguish them from those analogous changes often met with as the results of ordinary disease. These are confined to the mucous membrane of the stomach and bowels.
They are redness, ulceration, softening, and perforation. Each of these conditions may depend upon disease, as well as upon the action of irritant poisons.

Redness. — It is a main character of the irritants to produce redness of the mucous or lining membrane of the stomach and small intestines. This redness, when first seen, is usually of a deep crimson colour, becoming brighter by exposure to air. It may be diffused over the whole mucous membrane; at other times it is seen in patches, dots, or lines (striae), spread irregularly over the surface of the stomach. It is sometimes met with at the smaller, but more commonly at the larger end of this organ, and again we occasionally find that the folds or prominences only of the mucous membrane present this red or inflamed appearance. Redness of the mucous membrane may, however, be due to gastritis or gastro-enteritis; and in order to assign the true cause of the inflammation, it will be necessary to have an account of the symptoms preceding death, or some chemical proof of the existence of irritant poison in the contents of the stomach or the tissues of the body.

In the healthy state, the mucous membrane of the stomach is pale and white, or nearly so, except during digestion, when it becomes slightly reddened; and some observers have remarked that a slight redness has often remained in the stomachs of those who have died during the performance of the digestive process. When in contact with the spleen or liver, after death, the stomach is apt to acquire a deep livid colour from the transudation of blood; and it is well known that the bowels acquire a somewhat similar colour from the gravitation of blood which always takes place after death. None of these appearances are likely to be mistaken for the action of an irritant poison.

There is an important class of cases in which redness of the mucous membrane of the stomach is found after death, not dependent on the action of poison or on any assignable cause. These cases, owing to their being so little known, and involved in much obscurity, deserve much attention from the medical jurist, since the appearances closely resemble those produced by irritant poison. A person may die without suffering from any symptoms of disordered stomach; but on an inspection of the body, a general redness of the mucous membrane of this organ will be found, not distinguishable from the redness which is so commonly seen in arsenical poisoning. Several cases of this kind have occurred at Guy's Hospital; and drawings have been made of the appearance presented by the stomach, and are now preserved in the Museum collection.

The redness of the stomach, in cases of poisoning, is so speedily altered by putrefaction, when circumstances are favourable to this process, as frequently to render it impossible for a witness to speak with any certainty upon its cause. Putrefactive infiltrat-
tion from the blood contained in the adjacent viscera and muscles, will give a reddish-coloured appearance to a stomach otherwise in a healthy condition. Great dispute has arisen respecting the length of time during which redness of the stomach produced by an irritant will be recognisable and easily distinguishable from putrefactive changes. It is sufficient to say, that no certain rule can be laid down on the subject: it must be left to the knowledge and discretion of the witness. I have distinctly seen the well-marked appearances of inflammation produced by arsenic in the stomach and duodenum in an exhumed body twenty-eight days after interment (Reg. V. Jennings, Berks Lent Ass. 1845); and in another instance, referred to me by Mr. Lewis, the coroner for Essex, in August 1846, the reddened state of the mucous membrane, in the case of arsenical poisoning, was plainly perceptible on removing a layer of arsenic, nineteen months after interment. (See on this question, a case of suspected poisoning by Orfila, Annales d’Hyg. 1839, i. 127.) If, however, there be the least doubt respecting the origin of the discoloration, it would be unsafe to rely upon the appearance as evidence of poisoning, unless poison were detected.

Ulceration.—In irritant poisoning, the stomach is occasionally found ulcerated; but this is, comparatively speaking, a rare occurrence. In such cases the mucous membrane is removed in small distinct circular patches, under the edges of which the poison (arsenic) is often found lodged. Ulceration of the stomach is a more common result of disease, than of the action of poison. As a consequence of disease, it is very insidious, going on often for weeks together, without giving any indications of its existence, except perhaps slight gastric disturbance, with occasional nausea, vomiting, and loss of appetite. In this case the ulceration is commonly seen in small circumscribed patches. It is worthy of remark, as one means of diagnosis, that ulceration has never been known to take place from arsenic or any irritant poison, until symptoms indicative of irritant poisoning have occurred. In ulceration from disease, the mucous membrane is commonly only reddened in the neighbourhood of the ulcer. In ulceration from poison, the redness is generally diffused over other parts of the stomach, as well as over the duodenum and small intestines.

A case, however, occurred in Guy’s Hospital, some years ago, in which, with a small circular patch of ulceration near the cardiac opening, the whole mucous membrane was red and injected: but this singular condition of the stomach, so closely resembling the effects of an irritant poison, was unaccompanied by any marked symptoms of irritation during life. The history of a case previous to death will thus commonly enable us to determine, to what cause the ulceration found, may be due. Care must be taken to distinguish ulceration from corrosion. Ulceration is a vital process: the substance of a part is removed by the absorb-
SOFTENING. PERFORATION FROM POISONING.

ents as a simple result of inflammation. Corrosion, on the other hand, is a chemical action;—the parts are removed by the immediate contact of the poison: they are decomposed: their vitality is destroyed, and they combine with the corrosive matter itself. Ulceration requires time for its establishment, while corrosion is either an instantaneous or a very rapid effect.

Softening.—The coats of the stomach are not unfrequently found so soft, as to yield and break down under very slight pressure; and this may be the result either of poisoning, of some spontaneous morbid change in its structure during life, or of the solvent action of the gastric juice after death. As this condition in the stomach, when caused by poison, is commonly produced by those substances only which possess corrosive properties, it follows that in such cases, traces of their action will be perceived in the mouth, fauces, and oesophagus. In softening from disease, the change will be confined to the stomach alone, and it is commonly found only at the cardiac or greater end of the organ. When softening is really caused by an irritant poison, it is generally attended by other striking and unambiguous marks of its operation. Softening is not to be regarded as a common character of poisoning: it is only an occasional appearance. I have met with a case, in which the coats of the stomach were considerably hardened by sulphuric acid. Softening can never be inferred to have proceeded from poison, unless other well-marked changes are present, or unless the poison be discovered in the softened parts. The stomachs of infants have been frequently found softened from natural causes:—such cases could not be mistaken for poisoning, since the history during life, the want of other appearances indicative of poisoning, and the total absence of poison from the viscera, would prevent such a suspicion from being entertained.

Perforation.—The stomach may become perforated either as a result of poisoning or disease.

Perforation from poisoning.—This may occur in two ways:—1. By corrosion; 2. By ulceration. The perforation by corrosion is by far the most common variety of perforation from poisoning. It is occasionally witnessed where the strong mineral acids have been taken, especially sulphuric acid:—the stomach, in such cases, is blackened and extensively destroyed, —the aperture is large, the edges are rough and irregular, and the coats are easily lacerated. The poison escapes into the abdomen, and may be readily detected there by chemical analysis. The perforation from ulceration, caused by irritant poison (arsenic), is but little known. There are, so far as I know, only three instances on record. In a great number of poisoned subjects examined during many years past at Guy's Hospital, not a single case has occurred. It must, then, be looked upon as a very rare appearance in cases of irritant poisoning.
Perforation from disease.—This is by no means an unusual occurrence. Many cases of this description will be found reported elsewhere. (Guy's Hosp. Rep. No. 8.) It is invariably fatal when it proceeds so far that the contents of the stomach escape into the abdomen; but sometimes the stomach becomes glued to the pancreas during the ulcerative process, and then the individual may recover. Several specimens of this kind of adhesion have been met with in inspections. The symptoms from perforation commonly attack the individual suddenly, apparently while enjoying perfect health. Hence these cases may be easily mistaken for those of irritant poisoning. The principal facts observed with regard to this formidable disease are the following:—1. It often attacks young females from eighteen to twenty-three years of age. 2. The preceding illness is extremely slight; sometimes there is merely loss of appetite or capricious appetite, with uneasiness after eating. 3. The attack commences with a sudden and most severe pain in the abdomen, generally soon after a meal. In irritant poisoning, the pain usually comes on gradually, and slowly increases in severity. 4. Vomiting, if it exist at all, is commonly slight, and is chiefly confined to what is swallowed. There is no purging:—the bowels are generally constipated. In irritant poisoning, the vomiting is usually severe, and purging seldom absent. 5. The person dies commonly in from eighteen to thirty-six hours:—this is also the average period of death in the most common form of irritant poisoning, i.e. by arsenic;—but in no case yet recorded, has arsenic caused perforation of the stomach, within twenty-four hours; and it appears probable that a considerable time must elapse before such an effect could be produced by this or any irritant. 6. In perforation from disease, the symptoms and death are clearly referable to peritonitis. 7. In the perforation from disease, the aperture is commonly of an oval or rounded form, about half an inch in diameter, situated in or near the lesser curvature of the stomach, and the edges are smooth. The outer margin of the aperture is often blackened, and the aperture itself is funnel-shaped from within outwards, i.e. the mucous coat is the most removed, and the outer or peritoneal coat, the least. The coats of the stomach, round the edge of the aperture, are usually thickened for some distance; and when cut, they have almost a cartilaginous hardness. These characters of the aperture will not alone indicate whether it be the result of poisoning or disease; but the absence of poison from the stomach, with the want of other characteristic marks of irritant poisoning, would enable us to say, that disease was the cause. Besides, the history of the case during life would materially assist us in our diagnosis. The great risk in all these cases is, that the effects of disease may be mistaken for those of poisoning; for we are not likely to mistake a perforation caused by
irritant poison for the result of disease. Notwithstanding the well-marked differences above described, it is very common to meet with cases of imputed poisoning where death has really occurred from peritonitis following perforation. Within a recent period I have been required to examine several cases of this kind: one of them will be found elsewhere recorded (Guy’s Hosp. Reports, Oct. 1850, page 226). In another the body was exhumed after several months’ burial, and the stomach was found perforated from disease in the usual situation.

Spontaneous or Gelatinized Perforation.—The stomach is occasionally subject to a spontaneous change, by which its coats become softened and give way generally at the cardiac or greater end. As the effusion of the contents of the organ in such a case never gives rise to peritoneal inflammation, and no symptoms occur prior to death to indicate the existence of so extensive a destruction of parts, it is presumed to be a change in the dead body, and the stomach is supposed to undergo a process of solution or digestion. It is commonly attributed to the solvent action of the gastric juice,—the spleen, diaphragm, and other viscera being sometimes softened. (For some remarks on this subject, by Dr. Budd, see Med. Gaz. Vol. xxxix. p. 895.) In January, 1845, I met with an instance of this perforation in a child between two and three years of age. It was seized with convulsions, became insensible, and died twenty-three hours afterwards. After death, the greater end of the stomach was found destroyed to the extent of three inches; and the edges were softened and blackened. There was no food in the stomach, nor had anything passed into the organ for thirty-two hours before death! It was therefore impossible to ascribe death to the perforation, or the perforation to poison. (For a full account of this case, see Med. Gaz. Vol. xxxvi. p. 32.) An inspection of the body, with a general history of the case, will commonly suffice to remove any doubt in forming an opinion whether the extensive destruction so commonly met with, has or has not arisen from poison. Thus, in a cadaveric perforation, the aperture is always situated in that part of the stomach which lies to the left of the cardia, is very large, of an irregular form, and ragged and pulpy at the edges, which have the appearance of being scraped. The mucous membrane of the stomach is not found inflamed. There is occasionally slight redness, with dark brown or almost black lines (striae) in and near the dissolved coats, which have an acid reaction. It can only be confounded with perforation by the action of corrosives; but the well-marked symptoms during life, and the detection of the poison after death, together with the changes in the fauces and esophagus, will at once indicate the perforation produced by corrosive poison. A case of extensive perforation in the stomach, as the result of the action of the gastric fluids, has been reported by Dr. Barnes. (See Med. Gaz. Vol. xii. p. 298.)
CHAPTER IV.

RULES TO BE OBSERVED IN INVESTIGATING A CASE OF POISONING—WITH RESPECT TO THE PATIENT WHILE LIVING—THE INSPECTION OF THE BODY—THE EXHUMATION OF BODIES—DISPOSAL OF THE VISCERA. IDENTITY OF SUBSTANCES. PRESERVATION OF ARTICLES FOR ANALYSIS. ON THE USE OF NOTES—WHEN ALLOWED TO BE USED IN EVIDENCE—MEDICO-LEGAL REPORTS.

When a practitioner is called to a case of poisoning, it is above all things necessary that he should know to what points he ought to give his attention. It is very proper that every effort should be made by him to save life when the individual is living: but while engaged in one duty, it is also in his power to perform another, supposing the case to be one of suspected criminal poisoning,—namely, to note down many circumstances which may tend to detect the perpetrator of the crime. There is no person so well fitted to observe these points as a medical man; but it unfortunately happens, that many facts important as evidence are often overlooked. The necessity for observing and recording them is not perhaps generally known. A medical man need not make himself officious on such occasions, but he would be sadly unmindful of his duty as a member of society, if he did not aid the course of justice by extending his scientific knowledge to the detection of crime. It is much to the credit of the medical profession, that the crime of murder by poisoning—a form of death from which no caution or foresight can protect an individual, is so frequently brought to light, by the announcement of suspicious facts of a medical nature to magistrates and coroners; and on several occasions the highest compliments have been passed by judges, on medical practitioners who have been thus indirectly the means of bringing an atrocious criminal to the bar of justice.

The following appear to me to be the principal points which demand the attention of a medical jurist in all cases of suspected poisoning:—1. With respect to

SYMPTOMS.

1. The time of their occurrence,—their nature. 2. The exact period at which they were observed to take place after a meal, or after food or medicine had been taken. 3. The order of their occurrence. 4. Whether there was any remission or intermission in their progress, or, whether they continued to become more and more aggravated until death. 5. Whether the patient had laboured under any previous illness. 6. Whether the symptoms were observed to recur more violently after a particular meal, or
after any particular kind of food or medicine. 7. Whether the patient has vomited:—the vomited matters, if any (especially those first ejected), to be procured:—their odour, colour, and acid or alkaline reaction noted,—as well as their quantity. 8. If none be procurable, and the vomiting have taken place on the dress, furniture, or floor of a room,—then a portion of the clothing, sheet, or carpet, may be cut out and reserved for analysis;—if the vomiting have occurred on a deal floor, a portion of the wood may be scraped or cut out:—or if on a stone pavement, then a clean piece of rag or sponge soaked in distilled water, may be used to remove any traces of the substance. [Some years since, an animal was poisoned by arsenic. None of the poison could be detected in the stomach, but it was easily found in a portion of deal floor, rendered humid by the liquid matters which the animal had vomited during the night.] The vessel in which vomited matters have been contained will often furnish valuable evidence, since heavy mineral poisons fall to the bottom, or adhere to the sides of the vessel. 9. Endeavour to ascertain the probable nature of the food or medicine last taken, and the exact time at which it was taken. 10. Ascertain the nature of all the different articles of food used at a meal. 11. Any suspected articles of food, as well as the vomited matters, to be as soon as possible sealed up in a clean glass vessel, labelled, and reserved for analysis. 12. Note down, in their own words, all explanations voluntarily made by parties present, or who are supposed to be concerned in the suspected poisoning. 13. Whether more than one person partook of the food or medicine:—if so, whether all these persons were affected, and how? 14. Whether the same kind of food or medicine had been taken before by the patient or other persons without ill effects following. In the event of the death of the patient it will be necessary for the practitioner to note down—15. The exact time of death, and thus determine how long a period the person has survived after having been first attacked with the suspicious symptoms. 16. Observe the attitude and position of the body. 17. Observe the state of the dress. 18. Observe all surrounding objects. Any bottles, paper-packets, weapons, or spilled liquids lying about, should be collected and preserved. 19. Collect any vomited matters near the deceased. Observe whether vomiting has taken place in the recumbent position or not. If the person has vomited in the erect or sitting posture, the front of the dress will commonly be found covered with the vomited matters.

Inspection of the Body.

20. Note the external appearance of the body, whether the surface be livid or pallid. 21. Note the state of the countenance. 22. Note all marks of violence on the person, or discomposure of the dress,—marks of blood, &c. 23. Observe the presence or
absence of warmth or coldness in the legs, arms, abdomen, mouth or armpits. 24. The presence of rigidity or cadaverous spasm in the body. To give any value to the two last-mentioned characters, it is necessary for the practitioner to observe the nature of the floor on which the body is lying,—whether the body be clothed or naked, young or old, fat or emaciated. All these conditions create a difference, in respect to the cooling of the body and the access of rigidity. 25. If found dead—When was the deceased last seen living, or known to have been alive? 26. Note all circumstances leading to a suspicion of suicide or murder. 27. The time after death at which the inspection is made. 28. Observe the state of the abdominal viscera. If the stomach and intestines be found inflamed, the seat of inflammation should be exactly specified; also all marks of softening, ulceration, effusion of blood, corrosion, or perforation. The stomach should be removed and placed in a separate vessel, a ligature being applied at the cardiac and pyloric ends. If cut open for examination at this period, this should be performed in a clean dish and with such care, that none of the contents are lost or are allowed to mix with the contents of the intestines. 29. The contents of the stomach, if this organ be opened during the inspection, should be collected in a clean graduated vessel:—notice a the quantity, b the odour tried by several persons, c the colour, d acid or alkaline reaction; e presence of blood, mucus, or bile; f presence of undigested food: and here it may be as well to observe, that the presence of farinaceous matters (bread) would be indicated by the addition of iodine water, if the contents were not alkaline—of fat, by heat; g other special characters. 30. The contents of the duodenum should be separately collected, ligatures being applied to it. 31. Observe the state of the large intestines, especially the rectum, and note the condition of their contents. The discovery of hardened feces in the rectum would prove that purging had not existed recently before death. In one case which I was required to examine, this became a question of considerable importance. 32. The state of the larynx, fauces, and esophagus,—whether there be in these parts any foreign substances, or marks of inflammation and corrosion. This is of essential importance, as it throws light upon the question, whether the poison swallowed was irritant or corrosive, and whether it had or had not a local chemical action. 33. The state of the thoracic viscera; all morbid changes noted. 34. The state of the brain. 35. The condition of the uterus, ovaries, and genital organs should be examined, as, in the female, poison has been sometimes introduced into the system by the vagina. 36. The liver with the gall bladder should be removed for a chemical examination. 37. The urinary bladder, with any fluid contained in it, should be removed and placed in a separate jar.

Such are the points to which, in the greater number of cases
of suspected poisoning, a medical jurist should attend. By means of these data, noted according to the particular case to which they are adapted, he will in general be enabled, without difficulty, to determine the probable time of death, and the actual means by which death was brought about. He may thereby have it in his power also to point out the dish or article of food which had contained the poison, if the case be one of poisoning; and to throw light upon any disputed question of suicide or murder in relation to the deceased. Many cases of poisoning are rendered obscure, owing to these points not having been attended to in the first instance.

I have not considered it necessary to enter into any details respecting the mode of performing an inspection. This the practitioner will have acquired during his study of anatomy; and the only essential points in addition to those mentioned, are—1. To examine all the important organs for marks of natural disease; and 2. To note down any unusual pathological appearances, or abnormal deviations; although they may at the time appear to have no bearing on the question of poisoning. It is useful to bear in mind on these occasions, that the body is inspected, not merely to show that the individual has died from poison, but to prove that he has not died from any natural cause of disease. Medical practitioners commonly give their attention exclusively to the first point; while lawyers, who defend accused parties, very properly direct a most searching examination to the last-mentioned point, i.e. the healthy or unhealthy state of those organs which are essential to life, and with which the poison has not probably come in contact. The usual causes of sudden death have their seat commonly in the brain, the heart, and its great vessels, or in the lungs. Marks of effusion of blood, congestion, inflammation, suppuration, or a diseased condition of the valves of the heart, should be sought for and accurately noted, whatever may be the condition of the abdominal viscera. It has also been recommended that an examination of the spinal marrow should be made. If the cause of death be obscure after the general examination of the body, there may be some reason for inspecting the condition of this organ.

Exhumation of bodies. — Sometimes the inspection of a body is required to be made long after interment. So long as the coffin remains entire, there may be the expectation of discovering certain kinds of mineral poison in the organs; but decomposition may have advanced so far as to destroy all pathological evidence. The inspection is in such cases commonly confined to the abdominal viscera. The stomach is often found so thinned and collapsed, that the anterior and posterior walls appear to form only one coat. This organ should be removed, with the duodenum, and ligatures applied to each. The liver and the spleen should also be removed in order that they may, if necessary, be sep
rately analysed. If poison be not found in one or more of these viscera, it is not likely that it will be discovered in the body. It has been recommended that a portion of earth immediately above and below the coffin should be removed for analysis, as it may contain arsenic; but this appears to me to be an unnecessary piece of refinement, in those cases where the coffin is entire, or where the abdominal paries still cover the viscera. When decomposition has so far advanced as to have led to a mixture of earth with the viscera, and the poison is found in very minute quantity in the tissues only, the case may be regarded as doubtful. In giving a positive opinion upon such hyperchemical views, it might be fairly objected that traces of arsenic always exist in the iron and brass nails and ornaments which are used in a coffin; and this arsenic is just as likely to furnish a valid objection to medico-legal researches as that which is said to be a constituent of all soils in which oxide of iron abounds! The body of a deceased person, when exhumed, should be identified by some friend or relative, in the presence of the medical examiner. In one case of murder by poison the evidence almost failed, owing to this precaution not having been taken.

It is important that the viscera taken from a body which has been long in the grave should be sealed up immediately. They should not be allowed to come in contact with any metal, nor with any surface except that of clean glass, porcelain, or wood. It has been recommended that they should be washed with chloride of lime, or placed in alcohol; but this is decidedly improper: the use of any preservative chemical liquid would not only embarrass the future analysis, but would render a special examination of an unused portion of the liquid necessary—the identity of which would have to be unequivocally established. Preservation from air in clean glass vessels, with well-fitted corks, covered with skin, or, what is still better, sheet-caoutchouc, is all that is required in practice.

**Identity of Substances.**

It is necessary to observe, that all legal authorities rigorously insist upon proof being adduced of the identity of the vomited matters or other liquids taken from the body of a deceased person, when poisoning is suspected. Supposing that during the examination, the stomach and viscera are removed from the body, they should never be placed on any surface, or in any vessel, until we have first ascertained that the surface or vessel is perfectly clean. If this point be not attended to, it will be in the power of counsel to raise a doubt in the minds of the jury, whether the poisonous substance might not have been accidentally present in the vessel used. This may be regarded as a very remote presumption; but, nevertheless, it is upon technical objections of this kind, that acquittals follow, in spite
of the strongest presumptions of guilt. This is a question for which every medical witness should be prepared, whether he be giving his evidence at a coroner's inquest, or in a Court of law. Many might feel disposed to regard matters of this kind as involving unnecessary nicety and care, but if they be neglected it is possible that a case may be at once stopped: so that any care subsequently bestowed upon the chemical analysis by the practitioner, will have been labour thrown away. Evidence of the presence of poison in the contents of a stomach was once rejected at a trial for murder, because they had been hastily thrown into a jar borrowed from a neighbouring grocer's shop; and it could not be satisfactorily proved that the jar was clean and entirely free from traces of poison (in which the grocer dealt) when used for this purpose. When the life of a human being is at stake, as in a charge of murder by poisoning, the slightest doubt is always very properly interpreted in favour of the accused.

Not only must clean vessels be used for receiving any liquid destined for subsequent chemical analysis, but care must be taken by the practitioner that the identity of a substance is preserved, or the most correct analysis, afterwards made, will be inadmissible as evidence. The suspected substance, when once placed in his hands, should never be let out of his sight or custody. It should be kept sealed under his private seal, and locked up while in his possession, in a closet to which no other person has a key. If he has once let it out of his hands, and allowed it to pass through the hands of several other persons, then he complicates the evidence for the prosecution, by rendering it indispensable for these parties to state under what circumstances it was placed while in their possession. The exposure of a suspected substance on a table, or in a closet or room, to which many have access, may be fatal to its identity; for the chemical evidence, so important in a criminal investigation, will probably be altogether rejected by the Court. A case was tried on the Norfolk circuit, in which the analysis of the matters vomited by a person poisoned by arsenic, was not admitted as evidence against the prisoner, because the practitioner had let them in the keeping of two ignorant women; and these women had allowed the vessel containing the suspected liquid (which was proved to contain arsenic) to be exposed in a room open to the access of many persons. In another case, tried at the Old Bailey Sessions in 1835, the analysis of some suspected liquids was not allowed in evidence, because the practitioner, who lived in the country and was unwilling to take the responsibility of analysing them, had sent them up to town by a carrier, to be examined by a London chemist. If closely sealed by a private seal, and this be observed by the receiver to be unbroken, before he proceeds to the analysis, this mode of transmission will not
probably be objected to. When any article (e. g. a stomach or other organ) is reserved for analysis, care should be taken to attach immediately to it, or the vessel containing it, a parchment or wooden label upon which is plainly written in ink, the name of the deceased and the date of removal, including the day of the week and month. This is especially necessary when there are two or more articles for analysis. I have known the greatest inconvenience to result from the neglect of this simple precaution.

Preserving articles for analysis.—In removing viscera or liquids from the body, and reserving them for analysis, it is necessary to observe certain precautions. A clean vessel with a wide mouth should be selected; it should be only sufficiently large to hold the viscera or liquid (the less air remaining in it the better); it should be secured by a closely fitting cork, covered with fine skin or bladder. Another piece of skin should then be tied over the mouth, or, for this, sheet-coutchone may be substituted with advantage. It should lastly be covered with tin-foil, and a layer of white leather. In this way any loss by evaporation or decomposition is prevented, and the viscera may be preserved (in a cool place) for some time. If the mouth of the vessel be too wide for a cork, the other articles cannot be dispersed with; Paper only should not be used: I have known the appearances after death of the viscera of an infant, suspected to have died from poison, entirely destroyed by drying, from the evaporation which took place through the layers of paper with which the vessel in which they were contained, was covered. The practitioner should bear in mind that all these matters are likely to come out in evidence; and whatever is worth doing at all, is worth doing well. For reasons already stated, no antiseptic should be used. The addition of alum or alcohol to the viscera may seriously embarrass the analysis.

On the use of Notes.—It has already been recommended as a rule in these criminal investigations, that a practitioner should make notes of what he observes in regard to symptoms, appearances after death, and the results of a chemical analysis. His own observations should be kept distinct from observations made by others and reported to him. He may base his conclusions on the former, but not on the latter. From the common forms of law in this country, an individual charged with the crime of poisoning may remain imprisoned, if at a distance from the metropolis, for some months before he is brought to trial. It is obvious, however clear the circumstances may at the time appear to a practitioner, that it will require more than ordinary powers of memory to retain for so long a period, a distinct recollection of all the facts of the case. If he be unprovided with notes, and his memory be defective, then the case will turn in favour of the prisoner, for he will be the party to
benefit by the neglect of the witness. In adopting the plan here recommended such a result may be easily prevented. It may be remarked, that the law relative to the admissibility of notes or memoranda in evidence is very strict, and is rigorously enforced by the judges. In order to render such notes or memoranda admissible, it is indispensably necessary that they should be taken on the spot at the time the observations are made, or as soon afterwards as practicable; and further, it must be remembered that a witness can refer to them only for the purpose of refreshing his memory.

Medico-legal Reports.—One of the duties of a medical jurist is to draw up a report of the results of his examination: 1, in regard to symptoms; 2, in regard to the appearances after death; and, 3, in regard to the results of an analysis. With respect to the two first divisions of the report, I must refer the reader to the rules for investigating cases of poisoning. It need hardly be observed that the time at which the person was first seen, and the circumstances under which the attendance of the practitioner was required, as well as the period of death, should be particularly stated. The hour, the day of the week, and the day of the month, should be invariably mentioned. Some medical witnesses merely state the day of the week, without that of the month, or vice versa. At a trial this creates great confusion, by rendering a reference to almanacks necessary. The words yesterday, next day, &c. should never be used. The facts which it will be necessary to enter in the report are specially stated under the heads of investigation (see p. 28-30). If these facts be not observed in the order there set down, their value as evidence of the cause of death, or of the criminality of particular parties, will be entirely lost. In drawing up a report of symptoms and appearances after death, the facts should be in the first instance plainly and concisely stated seriatim, in language easily intelligible to non-professional persons. A reporter is not called upon to display his erudition, but to make himself understood. If technical terms are employed, their meaning should be stated in parentheses. When a subject is thoroughly understood, there can be no difficulty in rendering it in simple language; and when it is not well understood, the practitioner is not in a position to make a report. Magistrates, coroners, and barristers, are very acute, and easily detect ignorance, even when it appears under the mask of erudition.

In recording facts a reporter should not encumber his statements with opinions and inferences. His conclusions should be reserved until the end of the report. The language in which conclusions are expressed, should be precise and clear. It must be remembered that these are to form a concise summary of the whole report, upon which the judgment of a magistrate, or the decision of a coroner's jury, will be ultimately based. They
should be most strictly confined to the matters which are the subject of inquiry, and which have fallen under the observation of the witness. Thus, they commonly refer to the following questions. What was the cause of death? What are the medical circumstances which lead you to suppose that death was caused by poison? What are the circumstances which lead you to suppose that death was not caused by natural disease? Answers to one or all of these questions comprise, in general, all that the reporter is required to introduce into the conclusions of his report.

The reporter must remember, that his conclusions are to be based only upon medical facts,—not upon moral circumstances, unless he be specially required to express his opinion with regard to them, when they are of a medico-moral nature. Further, they must be founded only on what he has himself seen or observed. Any information derived from others, should not be made the basis of an opinion in a medico-legal report. It is scarcely necessary to remark, that a conclusion based upon mere probabilities is of no value as evidence.

In drawing up a report on the results of a chemical analysis, the following rules may be borne in mind. A liquid or solid is received for analysis. 1. When, and of whom, or how received? 2. In what state was it received—secured in any way, or exposed? 3. If more than one substance received, each to be separately and distinctly labelled; appearance of the vessel, its capacity, and the quantity of liquid (by measure) or solid (by weight) contained therein. 4. Where and when did you proceed to make the analysis, and where was the substance kept during the intermediate period? 5. Did any one assist you, or did you make the analysis yourself? 6. Physical characters of the substance. 7. Processes and tests employed for determining whether it contained poison. All the steps of these processes need not be described;—a general outline of the analysis will suffice. The magistrate may thus satisfy himself by an appeal to others (if necessary) whether the analysis has or has not been properly made. 8. Supposing the substance to contain poison,—is this in a pure state or mixed with any other body? 9. The strength of the poison, if an acid, or if it be in solution: in all cases, the quantity of poison present. 10. Supposing no poison to be contained in it, what was the nature of the substance? Did it contain anything likely to injure health or destroy life? 11. Could the supposed poisonous substance exist naturally or be produced within the body? 12. What quantity of the poison discovered would suffice to destroy life, and how far is the dose likely to be modified by age or disease?

There are few reports in which answers to most of these questions, although not formally put, will not be required: and unless the whole of them be borne in mind by the operator at
the time an analysis is undertaken, those which are omitted can never receive an answer, however important to the ends of justice that answer may ultimately become.

The results of analysis in the shape of sublimates or precipitates should be preserved as evidence distinctly labelled to correspond with the report in small glass tubes hermetically sealed. In this way they may be produced for examination at the inquest or trial.
IRRITANT POISONS.

CHAPTER V.

DIVISION OF IRRITANT POISONS. SULPHURIC ACID, OR OIL OF VITRIOL. SYMPTOMS CAUSED BY THIS POISON IN THE CONCENTRATED AND DILUTED STATE—APPEARANCES AFTER DEATH. QUANTITY OF ACID REQUIRED TO DESTROY LIFE—FATAL DOSES—PERIOD AT WHICH DEATH TAKES PLACE—TREATMENT—CHEMICAL ANALYSIS—MODE OF DETECTING THE POISON IN PURE AND MIXED LIQUIDS—ITS DETECTION IN ARTICLES OF CLOTHING—POISONING BY SULPHATE OF INDIGO.

General Remarks. — Irritant poisons may be divided into four groups—the non-metallic—the metalloids—the metallic—and those of an organic nature, i.e. derived from the vegetable and animal kingdoms. The non-metallic irritants comprise the mineral acids, oxalic acid, the alkalies, and their salts. According to strict chemical views, the alkalies and their salts should be placed among the metallic irritants; but it will be, in many respects, convenient to consider them in the same group with the acids. Besides, although they certainly have metallic bases, the demonstration of the existence of the metal is never required at the hands of a medical jurist, as in the case of the true metallic irritants. Among the mineral acids we shall first speak of poisoning by sulphuric acid.

SULPHURIC ACID, OR OIL OF VITRIOL.

Symptoms.—When this poison is swallowed in a concentrated form, the symptoms produced come on immediately, or during the act of swallowing. There is violent burning pain, extending through the fauces and oesophagus to the stomach—the pain is often so severe, that the body is bent. There is an escape of gaseous and frothy matter, followed by retching and vomiting, the latter accompanied by the discharge of shreds of tough mucus and of a liquid of a dark coffee-ground colour, mixed with blood. The mouth is excoriated, the lining membrane and surface of the tongue white, or resembling soaked parchment—in one instance the appearance of the mouth was as if it had
been smeared with white paint: after a time, the membrane acquires a grey or brownish colour; the cavity is filled with a thick viscid substance consisting of saliva, mucus, and the membrane of the mouth:—this renders speaking and swallowing difficult. If the poison has been administered by a spoon, or the phial containing it has been passed to the back of the fauces, the mouth may escape the chemical action of the acid. A medical witness must bear this circumstance in mind, when he is called to examine an infant suspected to have been poisoned by sulphuric acid. Around the lips and on the neck may be found spots of a brown colour from the action of the acid on the skin. There is extreme difficulty of breathing, owing to the swelling and excoriating of the fauces and larynx, and the countenance has from this cause a bluish or livid appearance;—the least motion of the abdominal muscles is attended with increase of pain. These symptoms have been sometimes mistaken for those of disease. (Henke, Zeitschrift der S. A. 1843, ii. 284.) The stomach is so irritable, that whatever is swallowed is immediately ejected, and the vomiting is commonly violent and incessant. In an interesting case communicated to the Medical Gazette by my friend Dr. Geoghegan, of Dublin, the patient (a female) vomited for three or four hours. This symptom then ceased, and did not recur, although she did not die until thirty-four hours after the poison had been swallowed. (Med. Gaz., Vol. xlviii. p. 328.) The matters first vomited generally contain the poison: they are acid, and if they fall on a limestone pavement there is effervescence, if on coloured articles of dress, the colour is sometimes altered to a red or yellow (if logwood), or the colour is discharged and the texture of the stuff destroyed:—on a black cloth dress, the spots produced by the concentrated acid are brown, and remain moist for a considerable time. An attention to these circumstances may often lead to a suspicion of the real cause of the symptoms, when the facts are concealed. After a time there is great exhaustion, accompanied by general weakness:—the pulse becomes quick, small, and feeble: the skin cold, mottled, and covered with a clammy sweat. There is generally great thirst, with obstinate constipation of the bowels;—should any evacuations take place, they are commonly either of a dark brown or leaden colour,—in some instances almost black, arising from the admixture of altered blood. There are sometimes convulsive motions of the muscles, especially those of the face and lips. The countenance, if not livid from obstructed respiration, is pale, expressive of great anxiety, and of the most dreadful suffering. The intellectual faculties are quite clear, and death usually takes place very suddenly, in from eighteen to twenty-four hours after the poison has been taken.

Appearances after death.—It has been remarked, that these are
not always to be found in the stomach; they may be confined to the region of the fauces and larynx. In an inspection of the body, the whole course of the alimentary canal, from the mouth downwards, ought to be examined; since in recent or acute cases it is in the oesophagus and fauces that we generally obtain strong evidence of the action of a corrosive poison. The discovery of the usual marks of corrosion in these parts is always highly corroborative of the signs of poisoning found in the stomach. During the inspection, the examiner must not omit to notice any spots on the skin produced by the action of the acid:—these are commonly of a dark brown colour, and are situated about the mouth, lips, and neck. The appearances met with in the body will vary, according to whether death has taken place rapidly or slowly. Supposing the case to have proved fatal very rapidly, the membrane lining the mouth will be found white, softened, and corroded; but this appearance may be absent. The mucous membrane of the fauces and oesophagus will commonly be found corroded, having sometimes a brownish or ash-grey colour. The corroded membrane of the oesophagus is occasionally disposed in longitudinal folds, portions of it being partly detached. The stomach, if not perforated, is collapsed and contracted. On laying it open, the contents are commonly found of a dark brown or black colour and of a tarry consistency, being formed in great part of mucus and altered blood. The contents may or may not be acid, according to the time the patient has survived, and the treatment which has been adopted. On removing them, the stomach may be seen traversed by black lines, or the whole of the mucous membrane may be corrugated, and stained black or of a dark brown colour. This blackness is not entirely removed by washing. On stretching the stomach, traces of inflammation may be found between the folds, indicated by a deep crimson red colour. On forcibly removing the blackened membrane, the red colour indicative of inflammation may be seen in the parts beneath. Both the dark colour and marks of inflammation are sometimes partial, being confined to insulated portions of the mucous membrane. When the stomach is perforated, the coats are softened, and the edge of the aperture is commonly black and irregular. In removing the stomach, the aperture is liable to be made larger by the mere weight of the organ. The contents do not always escape; but when this happens, the surrounding viscera are attacked by the poison. In a case which occurred at Guy's Hospital, the spleen, the liver, and the coats of the aorta, were found blackened and corroded by the acid, which had escaped through the perforation. When the person has survived for eighteen or twenty hours, traces of corrosive and inflammatory action may be found in the small intestines. In one case the mucous membrane of the ileum was corroded. The interior of the larynx as well as of the bronchial tubes, has also presented marks of the local
action of the acid. The acid has thus destroyed life without reaching the stomach. A remarkable instance in which the poison penetrated into and destroyed both lungs has been reported by Dr. Gull. (See Med. Gaz., Vol. xlv. p. 1102.) It is important for the medical witness to bear in mind, that the condition of the fauces and oesophagus above described is not constantly met with. Strange as it may appear, cases are recorded in which, notwithstanding the introduction of the poison into the stomach, the gullet has escaped its chemical action. Mr. Dickinson has reported a case of poisoning by sulphuric acid in which there was no corrosion of the mouth or fauces. The patient, a female, aged 52, recovered in about five months. The stomach had probably sustained injury, as the most urgent symptoms were constant vomiting after taking food, and obstinate constipation. The quantity of acid swallowed was half an ounce, mixed with half an ounce of water. The patient immediately felt a burning sensation at the pit of the stomach (Lancet, Nov. 26, 1853, p. 502). The acid had here evidently lost its corrosive power by dilution. (See Poisons—Sulphuric Acid.) When the acid has been taken in a still more diluted state, the marks of inflammation on the mucous membrane are more decided, and the blackening is not so considerable. Nevertheless, the acid, unless too much diluted, acts upon and darkens the blood in the vessels, as well as that contained in the stomach, although it may not blacken the mucous membrane or the contents.

Dr. Walker, of Inverness, gives a very full and instructive report of a case in which a man, aged 30, swallowed fifteen drachms and a half of sulphuric acid (sp. gr. 1.842), and died twenty-five hours afterwards. Half an hour after taking the poison he resembled a patient in the collapsed stage of cholera. The inside of the lips, tongue, and fauces were swollen, and had the appearance of being smeared with thin arrow-root. He suffered severe pain, but did not vomit until three-quarters of an hour had elapsed from the time of taking the poison: the vomiting appeared to be then excited by the liquid given to him. The vomited matters were dark, bloody and viscid. The patient was sensible up to the time of his death. An inspection revealed the usual appearances. The mucous membrane of the stomach was destroyed, and the whole surface darkened. The greatest amount of injury was at the pyloric end, where three small perforations were found. The orifice of the pylorus was swollen, constricted and hardened; it was so small as to admit only a silver probe. The duodenum had also suffered. The first two inches of the arch of the aorta were very much inflamed. There were no traces of the acid in the stomach; a slight trace in the duodenum: a trace in the serous fluid at the base of the brain; but the largest quantity was found in the blood contained in the heart. (Edin. Mon. Jour. June 1850, p. 538.) This case is
remarkable in the fact, that vomiting was not immediate; that there were no spots on the outside of the face; that the poison was swallowed in large quantity on an empty stomach; and there was free voluntary exertion, as, twenty hours after he had taken the poison, the man got out of bed and sat on a nightstool. Dr. Geoghegan, of Dublin, has published in the London Medical Gazette (vol. xlviii. p. 328), a full account of the symptoms and appearances after death in a well-marked case of poisoning by sulphuric acid, as well as of a process for detecting this poison when absorbed.

Quantity required to destroy life.—The dangerous effects of this poison appear to arise rather from its degree of concentration, than from the absolute quantity taken. The quantity actually required to prove fatal must depend on many circumstances. If the stomach be full when it is swallowed, the action of the acid may be spent on the food and not on the stomach; and a larger quantity might thus be taken than would suffice to destroy life if the organ were empty. The smallest quantity which is described as having proved fatal was in the following case. Half a tea-spoonful of concentrated sulphuric acid was given to a child about a year old by mistake for castor oil. The usual symptoms came on, with great disturbance of the respiratory functions; and the child died in twenty-four hours. The quantity here taken could not have exceeded forty drops. (Med. Gaz., Vol. xxxix. p. 147.) It is, however, doubtful whether this small quantity would have proved fatal to an adult. The smallest fatal dose which Dr. Christison states he has found recorded, was one drachm; it was taken, by mistake, by a stout young man, and killed him in seven days. (Op. cit. 162.)

Period at which death takes place.—It has been already stated, that the average period at which death takes place in cases of acute poisoning by sulphuric acid is from eighteen to twenty-four hours. When the stomach is perforated by the acid, it commonly proves more speedily fatal. In one instance, reported by Dr. Sinclair, a child about four years old died in four hours—the stomach was perforated. When the poison acts upon the larynx, death may be a still more speedy consequence from suffocation; and owing to this, it appears to be more rapidly fatal to children than adults. Dr. Craigie mentions a case in which three ounces of concentrated sulphuric acid destroyed life in three hours and a half; but the shortest case on record is, perhaps, that mentioned by Remer in Hufeland's Journal. In this instance death took place in two hours. A case is reported by Mr. Watson, in which a woman swallowed two ounces of the strong acid. She died in half an hour, but it appears that a quarter of an hour before death she had made a deep wound in her throat, which gave rise to great hemorrhage. The stomach was found extensively perforated:—but it is highly probable that the wound
PERIOD OF DEATH. CHEMICAL ANALYSIS.

accelerated death in this case. On the other hand, there are numerous instances reported, in which the poison proved fatal from secondary causes, at periods varying from one week to several months.

Chemical analysis.—This acid may be met with either concentrated or diluted; and a medical jurist may have to examine it under three conditions:—1. In its simple state.—2. When mixed with organic matters, as with liquid articles of food or in the contents of the stomach.—3. On solid organic substances, as where the acid has been thrown or spilled on articles of dress or clothing.

In the simple state.—If concentrated, it possesses these properties:—1. A piece of wood or other organic matter plunged into it, is immediately carbonised or charred.—2. When boiled with wood, copper-cuttings, or mercury, it evolves fumes of sulphurous acid; this is immediately known by the odour, as well as by the acid vapour first rendering blue, and then bleaching, starch-paper dipped in a solution of iodic acid.—3. When mixed with an equal bulk of water, great heat is evolved (nearly 300° F. in a cold vessel).

The diluted acid.—For the acid in a diluted state, but one test need be applied:—a solution of a salt of baryta,—the Nitrate of baryta, or the Chloride of barium. Having ascertained by test-paper, that the liquid is acid, we add to a portion of it a few drops of nitric acid, and then a solution of nitrate of baryta. If sulphuric acid be present, a dense white precipitate of sulphate of baryta will fall down—which is insoluble in all acids and alkalies. If this precipitate be collected, dried and heated to redness in a small platina crucible with five or six parts of charcoal powder, it will, if a sulphate, be converted to sulphuret of barium. To prove this, we add to the calcined residue, diluted muriatic acid, at the same time suspending over it a slip of filtering paper moistened with a solution of acetate of lead, or, what is more convenient, we place the residue on a slip of glazed card (coated with carbonate of lead,) scraped and wetted on the surface. (The card should be first tested for lead; because some kinds of glazed cards are made without lead.) If the original precipitate was sulphate, the gas now evolved will be sulphuretted hydrogen, known by its odour, and by its turning the salt of lead or staining the card of a brown colour. Instead of charcoal, we may use an equal bulk of cyanide of potassium as the reducing agent, and the experiment may then be performed in a small reduction-tube over a spirit lamp. On breaking the tube and placing the powder on a glazed card (containing lead) previously wetted, the stain of sulphuret of lead will be perceived; or the calcined residue may be dissolved in water
and tested. The smallest visible quantity of sulphate of baryta thus admits of easy detection.

In liquids containing organic matter.—If the sulphuric acid be mixed with such liquids as porter, coffee, or tea, the process for its detection is substantially the same, the liquid being rendered clear by filtration previously to adding the test. The sulphate of baryta, if mixed with organic matter, may be purified by boiling it in strong nitric acid; but this is not commonly necessary, as the reduction of the precipitate may be equally well performed with the impure, as with the pure sulphate. Some liquids generally contain sulphuric acid or a sulphate, such as vinegar and porter, but the acid is in very minute proportion; therefore, if there be an abundant precipitate, there can be no doubt, ceteris paribus, that free sulphuric acid has been added to them. Should the liquid be thick and viscid like gruel, it may be diluted with water, and then boiled with the addition of a little acetic acid. For the action of the test, it is not necessary that the liquid should be absolutely clear, provided it be not so thick as to interfere mechanically with the precipitation of the sulphate of baryta. So far with regard to articles administered, or of which the administration has been attempted. The same rules apply to the examination of matters vomited and of the contents of the stomach,—care being taken to separate the insoluble parts by filtration, before adding the test.

On solid organic substances. — It sometimes happens in cases of poisoning by sulphuric acid that it is spilled upon articles of clothing, such as cloth or linen, and here a medical jurist may succeed in detecting it, when every other source of chemical evidence fails. Again, sulphuric acid is often used for the purpose of seriously injuring a party, as by throwing it on the person,—an offence which, when accompanied with bodily injury, renders the offender liable to a severe punishment. On such occasions, proof of the nature of the corrosive liquid is required; and this is easily obtained by a chemical examination of a part of the dress. The process of analysis is very simple. The piece of cloth should be digested in a small quantity of distilled water at a gentle heat, whereby a brownish coloured liquid is commonly obtained on filtration. If sulphuric acid be present, the liquid will have a strong acid reaction, and produce the usual effects with the barytic test.

Sulphate of Indigo.

Several cases of accidental poisoning by this substance have occurred. As the compound is nothing more than a solution of indigo in strong sulphuric acid, the symptoms and appearances after death are the same as those which have been described for the latter substance. This kind of poisoning may be suspected when, with these symptoms the membrane of the mouth has a
blue or blue-black colour. The vomited matters, as well as the
faeces, are at first of a deep blue-black tint; afterwards green;
and it was observed in two instances that the urine voided by the
patients had a blue tinge.

It is proper to notice, that as Indigo is one of the substances
now directed by the statute to be mixed with arsenic when sold
in small quantities, the detection of this colouring principle in
the mouth and vomited matters will not necessarily show that it
has been taken in the form of sulphate.

CHAPTER VI

POISONING BY NITRIC ACID OR AQUA FORTIS. ACTION OF THE
CONCENTRATED ACID—APPEARANCES AFTER DEATH—QUANTITY
REQUIRED TO DESTROY LIFE—PERIOD AT WHICH DEATH TAKES
PLACE. PROCESSES FOR DETECTING THE POISON IN PURE AND
ORGANIC LIQUIDS.—POISONING BY HYDROCHLORIC ACID.

General Remarks.—Nitric acid is popularly known under
the name of Aqua fortis, or Red spirit of nitre. According to
Tartra, it seems to have been first used as a poison about the
middle of the fifteenth century. Although it is perhaps much
more used in the arts than oil of vitriol, cases of poisoning by it
are by no means common.

Symptoms.—When the acid is in a concentrated state, the
symptoms, on the whole, bear a close analogy to those produced
by sulphuric acid. They come on immediately, and the swal-
lowing of the acid is accompanied by the most intense burning
pain in the fauces and oesophagus, extending downwards to the
stomach:—there are gaseous eructations, from the chemical
action of the poison,—swelling of the abdomen, violent vomiting
of liquid or solid matters, mixed with altered blood of a dark
brown colour, and shreds of mucus, having a strong acid reaction.
The abdomen is generally exquisitely tender: but, in one well-
marked case of poisoning by this acid, the pain was chiefly con-
fined to the fauces: probably the poison had not reached the
stomach. The mucous membrane of the mouth is commonly
soft and white, after a time becoming yellow, or even brown; the
teeth are also white, and the enamel is partially destroyed by the
chemical action of the acid. There is great difficulty of speaking,
as well as of deglutition, the mouth being filled with viscid
mucus; the power of swallowing is sometimes entirely lost. On
opening the mouth, the tongue may be found swollen, and of a
citron colour; the tonsils are also swollen and enlarged. The
difficulty of respiration is occasionally such, as to render tracheo-
tomy indispensable, especially in young persons. (See case by Mr. Arnott, Med. Gaz. xii. 220.) As the symptoms progress, the pulse becomes small, frequent, and irregular; the surface of the body extremely cold, and there are frequent rigors. The administration of remedies,—even the deglutition of the smallest quantity of liquid, increases the severity of the pain, occasions vomiting, and gives rise to a feeling of laceration or corrosion. (Tarura, 144.) There is obstinate constipation. Death takes place in from eighteen to twenty-four hours, and is sometimes preceded by a kind of stupor, from which the patient is easily roused. The intellectual faculties commonly remain clear until the last. In one instance the patient was insensible, but she ultimately recovered. Death may be occasioned by this acid, in consequence of its action on the larynx, as in the case of sulphuric acid. Should the patient survive the first effects of the poison, the mucous membrane of the fauces and œsophagus may be discharged, either in irregular masses, or in the form of a complete cylinder of the œsophageal lining. There is great irritability of the stomach, with frequent vomiting and ultimate destruction of the powers of digestion: the patient becomes slowly emaciated, and dies from starvation or exhaustion.

The Vapour of this acid may destroy life. In March, 1854, Mr. Haywood, a chemist of Sheffield, lost his life under the following circumstances:—He was pouring a mixture of nitric and sulphuric acids from a carboy containing about sixty pounds, when by some accident the vessel was broken. For a few minutes he inhaled the fumes of the mixed acids, but it does not appear that any of the liquid fell over him. Three hours after the accident, he was sitting up and appeared to be in moderately good health. He was then seen by a medical man, and complained merely of some cuts about his hands. He coughed violently. In three hours more there was difficulty of breathing, with increase of the cough. There was a sense of tightness at the lower part of the throat, and the pulse was hard. At times he said he could scarcely breathe. He died eleven hours after the accident. On inspection, there was congestion of the trachea and bronchial tubes, with effusion of blood into the latter. The heart was flaccid, and contained but little blood; and the lining membrane of the heart and aorta was slightly inflamed. The blood gave a slightly acid reaction with test paper. The larynx was not examined. It is very probable that the seat of mischief was in this organ, and that the deceased died from inflammatory effusion and enlargement of the parts about the opening of the windpipe. (Lancet, April 15, 1854, p. 430.) The vapours produced by a mixture of strong nitric and sulphuric acids are of a most noxious and irritating kind. On one occasion, in preparing gun-cotton, I accidentally inhaled the vapour, and suffered from
severe constriction of the throat, tightness in the chest, and cough, for more than a week.

Appearances after death.—Supposing death to have taken place rapidly, the following appearances will be met with. The skin of the mouth and lips will present various shades of colour, from an orange yellow to a brown; it appears like the skin after a blister or burn, and is easily detached from the subjacent parts. Yellow spots produced by the spilling of the acid may be found about the hands and neck. A yellow frothy liquid escapes from the nose and mouth, and the abdomen is often much distended. The membrane lining the mouth is sometimes white, at others of a citron colour; the teeth are white, but present a yellowish colour about the corona. The pharynx and larynx are much inflamed; the latter sometimes oedematous. The lining membrane of the oesophagus is softened, and of a yellow or brown colour, easily detached, often in long folds. The trachea is more vascular than usual, and the lungs are congested. The most strongly marked changes are, however, seen in the stomach. When not perforated, this organ may be found distended with gas—its mucous membrane partially inflamed, and covered by patches of a yellow, brown, or green colour, or it may be even black. This green colour is due to the action of the acid on the colouring matter of the bile; but it must be remembered that a morbid state of the bile itself may give this appearance to the mucous membrane in many cases of death from natural disease. There is occasionally inflammation of the peritoneum, and the stomach is glued to the surrounding organs. Its coats are often so much softened, as to break down under the slightest pressure. In the duodenum similar changes are found; but in some cases the small intestines have presented no other appearance than that of slight vascularity. It might be supposed that the stomach would be in general perforated by this very corrosive substance; but this has not been often observed. Tartra only met with two instances, and in one of these the individual survived twenty, and in the other thirty hours. In giving this poison to rabbits, I have not found the stomach perforated, although the acid had evidently reached that organ, from its coats being stained of a deep yellow colour. In these experiments the non-perforation appeared to be due to the protective influence of the food with which the stomach was distended. In the very few cases that are reported in English journals, it would appear that the stomach has not been perforated: the poison had been swallowed soon after a meal, and its coats had thus escaped the corrosive action of the acid.

Quantity required to destroy life.—The smallest quantity of this acid which I find reported to have destroyed life, is about two drachms. It was in the case of a boy, aged thirteen; he died in about thirty-six hours. But less than this, even one drachm,
would doubtless suffice to kill a child; and, under certain circumstances, an adult; for the fatal result depends on the extent of the mischief produced by this corrosive poison in the larynx, oesophagus, and stomach. What is the largest dose of concentrated acid from the effects of which a person has recovered, it is difficult to say; since in most of the cases of recovery mentioned by authors, the quantity of the poison taken was unknown.

**Period at which death takes place.**—Sobernheim relates a case of poisoning by nitric acid, which proved fatal in one hour and three quarters. (Op. cit. 402.) This I believe to be the most rapidly fatal case on record, where the acid acted as a poison. The usual well-marked effects were found in the oesophagus, stomach, and duodenum. In infants, however, life may be destroyed by this poison in a few minutes, should it happen to affect the larynx. The longest case is, perhaps, that recorded by Tartra, where a woman perished from exhaustion, produced by the secondary effects of the poison, eight months after having swallowed it.

**Chemical analysis.**—*In the simple state.*—This acid may be met with either concentrated or diluted. The concentrated acid varies in colour from a deep orange red to a light straw yellow. It may be recognised,—1. By evolving acid fumes when exposed.—2. By its staining organic matter yellow or brown, the colour being heightened and turned to a reddish tint by contact with caustic alkalies.—3. When mixed with a few copper cuttings, it is rapidly decomposed—a deep red acid vapour is given off, and a greenish coloured solution of nitrate of copper is formed. Tin or mercury may be substituted for copper in this experiment.—4. The addition of gold-leaf and a few drops of hydrochloric acid. On warming the mixture if nitric acid be present the gold is dissolved. Common aqua fortis (nitric acid) frequently contains as impurity a sufficiency of hydrochloric acid to dissolve gold-leaf by heat.

*In the diluted state.*—This acid is not precipitated like the sulphuric by any common reagent, since all its alkaline combinations are soluble in water.—1. The liquid has a highly acid reaction, and on boiling it with some copper-turnings, red fumes of nitrous acid vapour are given off, unless the proportion of water be very great. At the same time, the liquid acquires a blue colour.—2. A streak made on white paper with the diluted acid does not carbonise it when heated; but a scarcely visible yellow stain is left.—3. The liquid is neither precipitated by nitrate of baryta nor by nitrate of silver. These two last experiments give merely negative results—they serve to show that the sulphuric and muriatic acids are absent.

In order to detect nitric acid, the liquid should be carefully neutralised by potash, and then evaporated slowly to obtain crystals. If the liquid contain nitric acid, these crystals will possess the following characters: —1. They appear in the form of
lengthened fluted prisms, which neither effloresce nor deliquesce on exposure. One drop of the solution evaporated spontaneously on glass will suffice to yield distinct and well-formed prismatic crystals. This character distinguishes the nitrate of potash from a large number of salts. — 2. When moistened with strong sulphuric acid, the powdered crystals slowly evolve a colourless acid vapour. By this test, the nitrate is known from every other degrading salt. — 3. A portion of the powdered crystals should be placed in a small tube and mixed with their bulk of fine copper filings. The mass is then to be moistened with water, and a few drops of strong sulphuric acid added. Either with or without the application of a gentle heat, a decomposition immediately ensues, by which red fumes of nitrous acid are evolved, recognisable by their colour, odour, and acid reaction. — 4. We add to the crystals a small piece of gold-leaf and muriatic acid; then boil for a few minutes. The gold will either wholly or entirely disappear if nitric acid or a nitrate be present. Its partial solution will be indicated by the addition of chloride of tin to the liquid after boiling.

In liquids containing organic matter. — Nitric acid may be administered in such liquids as tea, vinegar, or porter. In this case, besides the acid reaction, there will be a peculiar smell produced by the acid, when mixed with substances of an organic nature. The application of the usual tests is here counteracted: — thus, unless the quantity of nitric acid in the liquid be very considerable, the orange-red fumes of nitrous acid are not evolved on boiling the liquid with copper cuttings. If the liquid be viscid, this viscidity must be destroyed by dilution with water; — and in all cases, if any solid or insoluble substances be present, as in the matters vomited or contents of the stomach, it must be filtered, in order to separate the insoluble portions. This operation is commonly very slow. If we succeed in procuring a clear acid liquor, the colour may be disregarded. We should then carefully neutralise it with a weak solution of carbonate of potash. (Should the liquid thus procured not be acid, we may boil the organic substance itself with carbonate of potash.) The liquid may then be concentrated to a small bulk by evaporation, and a few drops crystallised on a piece of glass. The resulting crystals may be examined for those properties which have been described as characteristic of the compound of potash with nitric acid. The crystals so obtained may be coloured and impure. This circumstance does not at all interfere with the action of the most important test for nitric acid, namely the mixture of copper filings and sulphuric acid. The crystals may, however, if necessary, be purified by washing them with ether or alcohol. These liquids do not dissolve the nitrate of potash, but will often serve to remove from it the organic matters by which it is coloured. When either the nitric acid, or the nitrate to which it has
been converted, is mixed with common salt, the copper test cannot be employed. The gold test will in such a case furnish the best evidence. Muriatic acid may be added to the dried residue, with a small portion of gold-leaf, and the mixture boiled. If nitric acid or a nitrate be present, even in minute proportion, some portion of the gold will be dissolved—a fact demonstrable by the addition of chloride of tin.

Nitric acid may be detected in stains on clothing, if recent, by simply boiling the stained portion in water, with or without the addition of a small quantity of carbonate of potash. The carbonate must be used when an acid liquor is not obtained by boiling the stained cloth in distilled water.

HYDROCHLORIC ACID.

This acid, which is also called Muriatic acid, and is popularly known under the name of spirit of salt, is but seldom taken as a poison. In the few cases which have been hitherto observed, the symptoms and appearances have been similar to those caused by nitric acid. I have elsewhere related a case of poisoning by this acid (Guy’s Hosp. Rep. Oct. 1850, p. 211); and for another, in which a man recovered after swallowing one ounce, see Lancet, July 27, 1850, p. 113; also for a case of recovery from a similar dose, see Medical Gazette, Dec. 28, 1849. For a case of poisoning by the concentrated acid, and a well-marked record of the progress of the symptoms to a fatal termination, nearly eight weeks after the poison was taken, I must refer the reader to a paper by M. Alph. Guérard (Ann. d’Hyg. 1852, ii. 415).

CHAPTER VII.

POISONING BY THE VEGETABLE ACIDS. OXALIC ACID—SYMPTOMS AND EFFECTS—APPEARANCES AFTER DEATH—FATAL DOSES—RECOVERY FROM LARGE DOSES—PERIOD AT WHICH DEATH TAKES PLACE—TREATMENT—CHEMICAL ANALYSIS—TESTS FOR OXALIC ACID IN PURE AND MIXED LIQUIDS—BINOXALATE OF POTASH. TARTARIC ACID. ACETIC ACID. VINEGAR.

OXALIC ACID.

Symptoms.—In many instances of poisoning by oxalic acid, death has taken place so rapidly, that the individual has not been seen alive by a medical practitioner. If the poison be taken in a large dose, i. e., from half an ounce to an ounce of the crystals dissolved in water, a hot burning acid taste is experienced in the act of swallowing, with a sense of constriction or
OXALIC ACID. SYMPTOMS.

suffocation, and vomiting occurs either immediately, or within a few minutes. Should the poison be diluted, there is merely a sensation of strong acidity, and vomiting may not occur until after a quarter of an hour or twenty minutes. In some cases there has been little or no vomiting; while in others, this symptom has been incessant until death. In a case in which the poison was much diluted, vomiting did not occur for seven hours. (Christison, 221.) The vomited matters are highly acid, and have a greenish-brown or almost black colour; they consist chiefly of mucus and altered blood. In one instance, reported by Dr. Groghegan, they were colourless. (Medical Gazette, xxxvii. 792.) In another case, reported by Mr. Deane in the Provincial Journal, fluid blood of a bright arterial colour was vomited after some hours. (June 25th, 1851, p. 344.) There is great pain and tenderness in the epigastrium, with a burning sensation in the stomach, followed by cold clammy perspirations and convulsions. In a case which occurred at Guy's Hospital, in May, 1842, in which about two ounces of the poison had been swallowed, there was no pain. Urgent vomiting and collapse were the chief symptoms. There is in general an entire prostration of strength, so that if the individual be in the erect position, he falls; there is likewise unconscious loss of surrounding objects, and a kind of stupor, from which, however, the patient may be without difficulty roused. Owing to the severity of the pain, the legs are sometimes drawn up towards the abdomen. The pulse is small, irregular, and scarcely perceptible; there is a sensation of numbness in the extremities, and the respiration, shortly before death, becomes spasmodic. The inspirations are deep, and a long interval elapses between them. Such are the symptoms commonly observed in a rapidly fatal case.

Should the patient survive the first effects of the poison, the following symptoms appear: there is soreness of the mouth, constriction and burning pain in the throat, with painful deglutition.—tenderness in the abdomen, with irritability of the stomach, so that there is frequent vomiting, accompanied by diarrhea. The tongue becomes swollen, and there is great thirst. The patient may slowly recover from these symptoms. In a case related by Mr. Edwards to the Westminster Medical Society, the patient, a female, lost her voice for eight days. In the early editions of this work, I have treated it as doubtful whether the loss of voice in this case depended on the action of the poison. A case has, however, been reported by Mr. T. W. Bradley, from which it may be inferred that loss of voice may result from the direct effect of oxalic acid on the nervous system. A man swallowed a quarter of an ounce of the acid, and suffered from the usual symptoms in a severe form. In about nine hours, his voice, although naturally deep, had become low and feeble.
This weakness of voice remained for more than a month, and its natural strength had not returned even after the lapse of nine weeks. During the first month there was numbness, with tingling of the legs. (Med. Times, Sept. 14, 1859, p. 292.) The occurrence of this sensation of numbness, and its persistence for so long a period after recovery from the symptoms of irritation, clearly point to a remote effect on the nervous system. Spasmodic twitchings of the muscles of the face and extremities have also been observed in some instances. (See Lancet, March 22, 1851, page 329.)

**Appearances after death.**—The mucous membrane of the tongue, mouth, fauces, and oesophagus, is commonly white, as if bleached, but it is sometimes coated with a portion of the brown mucous matter discharged from the stomach. This latter organ contains a dark-brown mucous liquid, often acid, and having almost a gelatinous consistency. On removing the contents, the mucous membrane will be seen pale and softened, without always presenting marks of inflammation or abrasion, if death have taken place rapidly. This membrane is soft and brittle, easily raised by the scalpel, and presents much the appearance, which we might suppose it would assume, after having been for some time boiled in water. The small vessels are seen ramifying over the surface, filled with dark-coloured blood, apparently solidified within them. The lining membrane of the oesophagus (gullet) presents the same characters. It is pale, and appears as if it had been boiled in water, or digested in alcohol; it has been found strongly raised in longitudinal folds, interrupted by patches where the membrane has become abraded. In a case which was fatal in eight hours, the tongue was clotted with white specks; the oesophagus was not inflamed, but the stomach was extensively disorganised, and had a gangrenous appearance. Portions of the mucous membrane were detached, exposing the muscular coat. With respect to the intestines, the upper portion of the canal may be found inflamed; but unless the case be protracted, the appearances in the bowels are not very strongly marked. In a well-marked case of poisoning by this acid, however, which is recorded by Dr. Hildebrand, the mucous or lining membrane of the stomach and duodenum was much reddened, although the patient, a girl of 18, died in three-quarters of an hour after taking one ounce of the acid, by mistake for Epsom salts. (Casper's Vierteljahrschrift, 1853, 3 B. 2 H. page 256.) In a case of poisoning by this acid, in which two ounces had been taken, and death was rapid, the coats of the stomach presented almost the blackened appearance produced by sulphuric acid, owing to the colour of the altered blood spread over them. In protracted cases, the gullet, stomach, and intestines, have been found more or less inflamed.

Mr. Welch has communicated to me the particulars of a case
of poisoning by oxalic acid which occurred in April, 1853. A woman aged 28, swallowed three drachms of the crystallised acid. She was found quite dead in one hour afterwards. On examining the body, both lungs were observed to be extensively congested, and the heart and large vessels were full of dark-coloured blood. The stomach contained about three-quarters of a pint of dark-brown fluid, and its lining membrane was generally reddened. The other organs, excepting the brain, were healthy, and this presented appearances indicative of long-standing disease. This case is remarkable from the smallness of the dose, the rapidity of death, and the well-marked redness of the mucous membrane of the stomach. The diseased state of the body may have tended to accelerate death from the poison in this case. In one case the larynx was found filled with frothy mucus, and the left side of the heart and the lungs gorged with dark-coloured fluid blood. In a few cases there have been scarcely any perceptible morbid appearances produced.

It is worthy of remark that the glairy contents of the stomach do not always indicate strong acidity until after they have been boiled in water. Oxalic acid does not appear to have a strongly corrosive action on the stomach, like that possessed by the mineral acids. It is therefore rare to hear of the coats of the organ being perforated by it. In many experiments on animals, and in some few observations on the human subject, I have found nothing to bear out the view that perforation is a common effect of the action of this poison. The acid undoubtedly renders the mucous coat soft and brittle, and perforation may occur either during life or after death as a result of this chemical action. Dr. Wood has recorded the case of a female, s. t. 27, found dead, whose death had been obviously caused by oxalic acid, but the quantity taken, and the duration of the case, were unknown. The stomach presented, at its upper and fore part near the cardiac opening, an irregular aperture of a size to admit the point of the finger. From this a dark gelatinous-looking matter, resembling coffee-grounds, was escaping in abundance. The perforation was enlarged by removal, and presented the appearance of two large apertures separated by a narrow band. The stomach contained a bloody fluid in which oxalic acid was detected, and the mucous membrane presented an eroded appearance. The jejunum and ileum were similarly affected.

Quantity required to destroy life.—The smallest quantity of this poison which has been known to destroy life was one drachm (sixty grains). The boy, s. t. 16, was a patient of Dr. Barker’s, of Bedford. He took the poison in a solid form, and was found in an hour insensible, pulseless, and his jaws spasmodically closed. He had vomited some bloody matter: his tongue and lips were unusually pale, but there was no excoriation. He died in eight hours. (Lancet, Dec. 1, 1855.) In Mr. Welch’s
case (suprâ) three drachms destroyed life in an hour. Two cases occurred at Guy’s Hospital, in each of which half an ounce of oxalic acid had been swallowed. Active treatment was adopted, and both patients recovered. When the dose is upwards of half an ounce, death is commonly the result; but one of my pupils informed me of a case in which a man recovered, after having taken one ounce of crystallised oxalic acid. Dr. Brush, of Dublin, has communicated to the Lancet, a case in which recovery took place perfectly after a similar dose of the poison had been taken. (See also a case by Mr. Allison in the same journal, Nov. 2, 1850, p. 502.) The acid was in this instance taken by mistake for Epsom salts.

Period at which death takes place.—Equal quantities of this poison do not destroy life within the same period of time. In two cases, in which about two ounces of the acid were respectively taken, one man died in twenty minutes,—the other in three-quarters of an hour. Dr. Christison mentions an instance in which an ounce killed a girl in thirty minutes; and another in which the same quantity destroyed life in ten minutes. Dr. Ogilvy, of Coventry, has reported a case of poisoning by oxalic acid, in which it is probable that death took place within three minutes after the poison had been swallowed. The sister of the deceased had been absent from the room about that period, and on her return found her dying. The quantity of poison taken could not be determined. When the dose of oxalic acid is half an ounce and upwards, death commonly takes place in an hour. There are, it must be admitted, numerous exceptions to this rapidity of action. Dr. Christison reports two cases, which did not prove fatal for thirteen hours; and in an instance that occurred to Mr. Fraser, in which only half an ounce was taken, the individual died from the secondary effects in a state of perfect exhaustion, twenty-three days after taking the poison.

Chemical analysis. In the simple state.—This acid may be met with, either as a solid, or in solution in water. Solid oxalic acid: It is seen more or less perfectly crystallised in four-sided prisms, in which respect it differs from all other common acids, mineral and vegetable. The crystals are unchangeable in air. They are soluble in water and alcohol, forming a strongly acid solution.

Tests.—1. Nitrate of silver. When added to a solution of oxalic acid, it produces an abundant white precipitate of oxalate of silver. A solution containing so small a quantity of oxalic acid as not to redder litmus-paper, is affected by this test; but when the quantity of poison is small, it would be always advisable to concentrate the liquid by evaporation before applying it. The oxalate of silver is identified by the following properties: 1. It is completely dissolved by cold nitric acid. If collected on a filter, thoroughly dried, and heated on thin platina.
It is simply assumed that we have a plane for which the angles 90° and 90° are the only ones that make sense. In this case, the plane is a right triangle and the angles are 90° and 90°. The plane is divided into four quadrants, each with a 90° angle. The plane can be moved to any position, as long as the angles remain 90° and 90°.

As the plane is moved, it will be noticed that the angles change, but the plane remains a right triangle. The plane is then moved to another position, and it is noticed that the angles remain 90° and 90°. The plane is then moved to another position, and it is noticed that the angles remain 90° and 90°. The plane is then moved to another position, and it is noticed that the angles remain 90° and 90°. The plane is then moved to another position, and it is noticed that the angles remain 90° and 90°. The plane is then moved to another position, and it is noticed that the angles remain 90° and 90°. The plane is then moved to another position, and it is noticed that the angles remain 90° and 90°. The plane is then moved to another position, and it is noticed that the angles remain 90° and 90°. The plane is then moved to another position, and it is noticed that the angles remain 90° and 90°. The plane is then moved to another position, and it is noticed that the angles remain 90° and 90°. The plane is then moved to another position, and it is noticed that the angles remain 90° and 90°. The plane is then moved to another position, and it is noticed that the angles remain 90° and 90°. The plane is then moved to another position, and it is noticed that the angles remain 90° and 90°. The plane is then moved to another position, and it is noticed that the angles remain 90° and 90°. The plane is then moved to another position, and it is noticed that the angles remain 90° and 90°. The plane is then moved to another position, and it is noticed that the angles remain 90° and 90°. The plane is then moved to another position, and it is noticed that the angles remain 90° and 90°. The plane is then moved to another position, and it is noticed that the angles remain 90° and 90°. The plane is then moved to another position, and it is noticed that the angles remain 90° and 90°. The plane is then moved to another position, and it is noticed that the angles remain 90° and 90°.
they must be dissolved in water, and tested in the manner above directed.

The quantity of this poison found in the stomach is generally small. In one case, in which about an ounce and a half had been taken, and the person died in two hours, I found only thirteen grains. This is owing to the ejection of the greater portion by vomiting. In the case of Reg. v. Cochrane, (Liverpool Summer Assizes, 1857,) in which it was charged that two children, aged six and four years respectively, had been wilfully poisoned by their mother, it was stated by the medical witness, Dr. Edwards, that he found forty-two grains of oxalic acid in the stomach of the elder, and twenty grains in that of the younger child. It was not clearly established when or how this large quantity of poison could have been administered to the children, and the prisoner was acquitted.

Binoxalate of Potash, or Salt of Sorrel.

Symptoms and effects.—The poisonous effects of this salt entirely depend on the oxalic acid which it contains. It is said to be much used for the purpose of bleaching straw and removing inksprints—being sold under the name of essential salt of lemons. Its poisonous properties are not commonly known, or no doubt it would be frequently substituted for oxalic acid. Three cases of poisoning by this substance have occurred within a recent period:—two of these proved fatal, while in the other, the patient recovered.

In the case of recovery, a young lady, aged twenty, swallowed an ounce of the salt dissolved in warm water. She was not seen by any one for an hour and a half; she was then found on the floor, faint and exhausted, having previously vomited considerably. There was great depression, the skin cold and clammy, the pulse feeble, and there was a scalding sensation in the throat and stomach. There was also continued shivering. Proper medical treatment was adopted, and she recovered in two days, still suffering from debility and great irritation of the stomach. During the state of depression, it was remarked that the conjunctivae (membranes of the eyes) were much injected, and the pupils dilated. There was also great dimness of vision. (Med. Gaz., Vol. xxvii. p. 480.)

This salt destroys life almost as rapidly as oxalic acid itself: and in the symptoms which it produces, it closely resembles that poison. In one case, half an ounce killed an adult in so short a time as eight minutes; but probably the fatal effects were in this instance accelerated by the debilitated state of the person who took it. In another case, reported by M. Chevallier, death took place in ten minutes. (Ann. d’Hyg., 1850, Vol. i. p. 162.)

Chemical analysis.—Its solution might be readily mistaken for oxalic acid: for, 1st, it has an acid reaction; and 2nd, it is pre-
TARTARIC ACID. ACETIC ACID.

57

crystallized by nitrate of silver and sulphate of lime, like oxalic acid: but with respect to the latter test, the precipitation, although more slowly produced, is much more copious. It is distinguished from oxalic acid — 1. By its crystalline form, which, as seen in a few drops evaporated on glass, is plumose; and 2. By heating a portion on platina foil. While oxalic acid is volatile, the binoxalate leaves an ash, which, when sufficiently calcined, is alkaline; and it may be proved to contain potash by its dissolving in diluted nitric acid, with effervescence, and forming nitrate of potash.

TARTARIC ACID.

Symptoms and appearances. — Tartaric acid has not been considered to possess any poisonous properties; but one case has occurred, in which there was no doubt that it acted as an irritant, and destroyed life. The case referred to was the subject of a trial for manslaughter at the Central Criminal Court (Reg. v. Watkins) in January, 1845. The accused gave the deceased, a man aged twenty-four, by mistake, one ounce of tartaric acid instead of aperient salts. The deceased swallowed the whole dissolved in half a pint of warm water at a dose; he immediately exclaimed that he was poisoned; he complained of a burning sensation in his throat and stomach, as though he had drunk oil of vitriol, and that he could compare it to nothing but being all on fire. Soda and magnesia were administered with diluent drinks. Vomiting set in, and continued until death, which took place nine days afterwards. On inspection, nearly the whole of the alimentary canal was found highly inflamed. The accused admitted that he had made a mistake, and tartaric acid was found in the dregs of the cup. The jury acquitted the prisoner. Another case of poisoning by this acid, with a report of the results of analysis, has been recently published by M. Devergie. (Ann. d’Hyg., 1851, ii. 432.) This case gave rise to a controversy between the late M. Orfila and M. Devergie, the points in dispute relating chiefly to the processes for the detection of the acid in the stomach and tissues. (See Ann. d’Hyg., 1852, i. 199, 382, and ii. 230.)

ACETIC ACID.

This acid has been generally excluded from the class of poisons. Common vinegar, which contains only five per cent. of acetic acid, has often been taken in large doses without injurious consequences. From the experiments performed by Orfila on dogs, and from one case which he reports as having occurred in the human subject, acetic acid, when concentrated, appears to exert an irritant action on the body. (Annales d’Hygiène, 1831, ii. 159: also Toxiciologie, ii. 198.) This is not more than we might have expected, seeing that the concentrated acid is highly corrosive. In the case referred to, the deceased, a young female aged nineteen, was found dying on the highway. She suffered from
convulsions, and complained of pain in the stomach, and died in a very short time. On inspection, the stomach was found neither softened nor corroded, but its mucous membrane near the pylorus was almost black. The mucous glands were prominent, and the vessels were filled with black coagulated blood.

Vinegar, which may be regarded as an organic mixture containing but a very small proportion of acetic acid (five per cent.), may be examined by distilling a portion, and testing the distilled liquid for the acid. Vinegar, as it exists in commerce, always contains traces of sulphuric acid. In general it is easily recognised by its odour. Pelletan observed in the case of a child that the abuse of vinegar led to a thinning of the mucous membranes of the stomach; and Landerer remarked that the milk of a wet-nurse who had been in the habit of taking large quantities of the Vinegar of Roses, became thin, very acid, and deficient in casein and oil. The infant which she was suckling gradually wasted and died, and the woman herself suffered severely. (Heller’s Archiv, 1847, 2 H. S. 185.)

CHAPTER VIII.

POISONING BY THE ALKALIES. — POTASH, SODA, AND THEIR CARBONATES—SYMPTOMS—FATAL EFFECTS OF THE CARBONATE OF POTASH—APPEARANCES AFTER DEATH—TREATMENT—AMMONIA AND SESQUICARBONATE OF AMMONIA (SAL VOLATILE)—CHEMICAL ANALYSIS—TESTS FOR POTASH AND SODA—TESTS FOR AMMONIA.

POTASH AND SODA.

Symptoms.—The symptoms produced by potash and soda, when taken in a large dose, are so similar that one description will serve for both. It must be observed that cases of alkaline poisoning are extremely rare, and have been, I believe, hitherto the result of accident. The most common form in which these poisons are met with, is in the state of pearlash (carbonate of potash) and soap-lees (carbonate of soda). The patient experiences during the act of swallowing an acid caustic taste, owing to the alkaline liquid, if sufficiently concentrated, excoriating the mucous membrane. There is a sensation of burning heat in the throat, extending down the gullet to the stomach. Vomiting is not always observed; but when it does occur, the vomited matters are sometimes mixed with blood of a dark brown colour, and with detached portions of mucous membrane;—this effect depending on the degree of causticity in the liquid swallowed. The surface is cold and clammy;—there is purging, with severe pain in the abdomen, resembling colic. The pulse is quick and feeble. In the
course of a short time, the lips, tongue, and throat, become swollen, soft, and red.

Appearances after death. — In recent cases there are strong marks of the local action of the poison on the mucous membrane of the mouth, throat, and gullet. This membrane has been found softened, detached, and inflamed in patches of a deep chocolate colour, — sometimes almost black. The same appearance has been met with in the mucous membrane of the larynx and trachea. The stomach has had its mucous surface eroded in patches, and there has been partial inflammation.

Period of death. — The most rapidly fatal case which I have found reported is that of a boy, who died in three hours after swallowing three ounces of a strong solution of carbonate of potash. In another case, which occurred in 1835, a child, aged three years, took a small quantity of pearlash, which had deliquesced, and died in twenty-four hours. Death was caused in this instance by the inflammation induced in the larynx, causing an obstruction to the process of respiration. In this respect, the caustic alkalies may destroy life like the mineral acids. But death may be a slow result of these poisons. Thus in an instance which was communicated to me, a lady swallowed, by mistake, one ounce and a half of the common solution of potash of the shops, which contains about five per cent. of caustic alkali. She recovered from the first symptoms of irritation, but died seven weeks afterwards, from pure exhaustion, becoming greatly emaciated before her death.

Dr. Barclay has reported a case of chronic poisoning by potash, which furnishes a good illustration of the after-effects and appearances caused by this poison. A woman, aged forty-four, was admitted into St. George's Hospital, May 2, 1853, about six hours and a half after she had swallowed a quantity of American potash,—probably a saturated solution of carbonate of potash (American pearlash). She had vomited immediately after taking it. The mouth and fauces were much corroded. There was burning pain in the throat and gullet, extending downwards to the stomach; but there was no tenderness on pressure. Two days after her admission there was a little vomiting. The mucous membrane, as far as could be seen, was abraded; there was difficulty of swallowing, and occasionally pain after food had entered the stomach. In about a month there was frequent vomiting, with pain on pressure, and constipation; when food or medicine was taken, there was much pain in the stomach, and in a short time the food was ejected. As the case progressed nothing could be retained on the stomach, and shortly before death the patient was supported only by nutritive injections. She died from starvation on the 8th July, about two months after taking the alkali. On inspection the lower part of the gullet was found much contracted, the lining membrane entirely destroyed, and the muscular coat exposed.
The external coats were much thickened. The cardiac orifice of the stomach, where the ulceration ceased, was considerably contracted. At the pyloric end, the mucous lining presented a large and dense cicatrix, obstructing all communication with the duodenum except by an orifice no larger than a probe. The intervening portion of the stomach was healthy, as were also the large and small intestines. (Med. Times and Gazette, Nov. 26, 1853, p. 554.)

Orfila refers to two cases of poisoning by carbonate of potash, in each of which half an ounce of this substance was taken by mistake for aperient salts. The patients, two young men, recovered from the first effects, but ultimately died; the one three months, and the other four months, after the poison had been taken. The secondary fatal effects appear to be due to constant purging, great irritability of the stomach leading to incessant vomiting, or loss of the functions of this organ from the destruction of the lining membrane, and stricture either of the gullet or of the apertures of the stomach,—any of which causes may prove fatal at almost any period. A fatal case of stricture, produced by soap-lees after the lapse of two years and three months, is reported by Dr. Basham (Lancet, March 2, 1850). The constant use of the alkalies or their carbonates appears to be productive of latent mischief; yet the quantity which may be sometimes taken in divided doses without destroying life is enormous. Dr. Tunstall, of Bath, relates the case of a man who, for eighteen years had been in the habit of taking bicarbonate of soda to remove dyspepsia. It is stated that for sixteen years he took two ounces of the bicarbonate daily! The man died suddenly, and on examining the stomach it was found to be greatly distended and extensively diseased,—conditions which were referred by Dr. Tunstall to the action of the carbonate of soda (Med. Times, Nov. 30, 1850, p. 564).

Quantity required to destroy life.—The quantity of any of these alkaline poisons required to destroy life is unknown.

Chemical analysis.—Caustic Potash and Soda are known from their respective carbonates by giving a brown precipitate with a solution of nitrate of silver. The Carbonates, on the other hand, yield a whitish-yellow precipitate. Caustic potash is known from caustic soda by the following characters:—1. Its solution, when not too much diluted with water, is precipitated of a canary-yellow colour by perchloride of platina. 2. It is precipitated in granular white crystals, on adding the alkaline liquid gradually to a strong solution of tartaric acid, and occasionally stirring the mixture, or by dissolving in it a large crystal of tartaric acid. Caustic soda is not precipitated by either of these tests, which will serve equally to distinguish the salts of potash from those of soda, if we except the binoxalate and bitartrate of potash, which, from being but little soluble in water, are not pre-
POISONING BY AMMONIA.

3. If we neutralise the two alkalies by diluted nitric acid, and crystallise the liquid on a slip of glass, should the alkali be potash, the crystals will have the form of long slender fluted prisms; if soda, of rhombic plates.

In liquids containing organic matter.—Such liquids are frothy; they possess an alkaline reaction, a peculiar alkaline odour, and are unctuous to the feel. The organic liquid may be evaporated to dryness, then heated to char the animal and vegetable matter, and the alkali will be recovered from it in a state of carbonate, by digesting the residuary ash in distilled water.

AMMONIA. SPIRIT OF HARTSHORN.

The vapour of strong ammonia is poisonous. It may destroy life by producing violent inflammation of the larynx, or by causing pneumonia. It is often most injudiciously employed to rouse persons from a fit. A case is on record of an epileptic having died under all the symptoms of croup, two days after the application of strong ammonia, in this way, to the nostrils. A very singular case of recovery from the poisonous effects of this vapour, by Dr. Sanchard, will be found reported in the Annales d'Hygiène (Janvier 1841).

The strong solution of ammonia produces symptoms similar to those described in speaking of potash. The only difference observed is, that the sense of heat and burning pain in the throat, fauces, and stomach, is much greater. Cases of this form of poisoning are rare. Dr. Sanchard relates an instance that occurred in France, in which a boy, only six years old, poisoned his younger sister by pouring several teaspoonfuls of a strong solution of ammonia down her throat. A case is likewise reported in which a strong dose of the solution killed a man in four minutes. (Christison, 167.) Another case is referred to in the Journal de Pharmacie (Oct. 1846, p. 285), in which from one to two drachms of ammonia, unknowingly administered, caused death. There was violent vomiting, with bloody stools; and, on inspection, blood was found effused in the intestines. There was also a remarkably fluid state of the blood in the body. In another instance, a man walked into a druggist's shop, and asked for a small quantity of ammonia to take spots out of his clothes. The druggist poured about a teaspoonful and a half into a glass. The man suddenly swallowed it, and fell instantly to the ground. He soon afterwards died, complaining of the most excruciating pain. (Journal de Chimie Médicale, 1845, 531.) A similar case occurred at Halifax in April 1857. A man swallowed a large dose of ammonia and died in a quarter of an hour.

Serious injury to the organs of respiration is sometimes the result of the action of this poison, as in the following case, which was referred to me for examination by my colleague, Mr. Hilton, in May 1857. A gentleman liable to attacks of fainting died in
three days, after swallowing a quantity of a liquid administered to him by his son. This liquid, which was at the time believed to be sal volatile, was, in fact, a strong solution of ammonia. The deceased complained immediately of a sensation of choking and strangling in the act of vomiting. Symptoms of difficulty of breathing set in, with other signs of irritation in the throat and stomach. The mucous membrane of the mouth and fauces was corroded and dissolved; and it was evident that the liquid had caused great local irritation. The difficulty of breathing was such as to threaten suffocation, and at one time it was thought that an operation must be resorted to. The state of the patient, however, precluded its performance, and he died on the third day. On inspection, the visceræ presented strong marks of corrosion. The covering of the tongue was softened and had peeled off; the lining membrane of the trachea and bronchi was softened and covered with layers of false membrane, the result of inflammation,—the larger bronchial tubes were completely obstructed by casts or cylinders of this membrane. The lining membrane of the gullet was softened, and at the lower part near its junction with the stomach, the tube was completely dissolved and destroyed. There was an aperture in the stomach in its anterior wall, about one inch and a half in diameter; the edges soft, ragged, and blackened, presenting an appearance of solution. The contents of the stomach had escaped. On the inside, the vessels were injected with dark-coloured blood, and there were numerous small effusions of blood in various parts of the mucous membrane. The coats were thinned and softened at the seat of the aperture. The blackened and congested appearance somewhat resembled that which is seen in poisoning by sulphuric or oxalic acid. The mucous matter on the coats of the stomach was feebly acid. No poison of any kind was found in the layer of mucus or in the coats. There was not in any part the slightest trace of ammonia, the poison which had caused the mischief. The deceased had lived three days: remedies had been used, and every trace of ammonia had disappeared. The immediate cause of death was an obstruction of the air tubes, as a result of inflammation, caused by the irritant action of the poison. It was quite obvious that a quantity of the liquid had entered the wind-pipe. The perforation of the stomach had probably taken place shortly before death, or there would have been marks of peritonitis. The injury to the stomach and oesophagus would have been sufficient to cause death, even supposing that the liquid had not penetrated to the lungs.

Sesquicarbonate of ammonia.—The solution of this salt (sal volatile) is probably more active as a poison than is commonly supposed. The following case occurred to my knowledge in 1832. A man, in a fit of passion, swallowed about five fluid-drachms of a solution of sal volatile. In ten minutes, he was
seized with stupor and insensibility; but upon the application of stimulant remedies he recovered. He suffered for some time afterwards, from severe irritation about the fauces and oesophagus. Mr. Iliff, jun., reports the case of a little boy, aged two years, who swallowed about half an ounce of strong solution of spirits of hartshorn, and in spite of rather severe symptoms recovered in a few days. (Lancet, Dec. 1, 1849.)

In a paper above referred to, Dr. Barclay relates the case of a female, aged 19, who, while in a state of unconsciousness, was made to swallow a quantity of hartshorn. She felt a severe pain in the stomach immediately afterwards, and in about an hour she vomited some blood. This vomiting of blood continued for several days. These symptoms were followed by great irritability of the stomach, and the constant rejection of food. There was obstinate constipation of the bowels, with great emaciation and loss of strength. She died in about three months from the time at which she had swallowed the alkaline poison. On inspection, the gullet was found healthy; the orifice, at its junction with the stomach, was slightly contracted. The pyloric orifice was contracted to the size of a crowquill, and the coats were thickened. On the posterior wall of the stomach, there was a dense cicatrix of the size of half a crown, and from this point fibrous bands ramified in various directions. The duodenum and other parts of the intestinal canal were healthy. (Med. Times and Gazette, Nov. 26, 1858, p. 554.) A case occurred to Mr. Procter, in May, 1852, in which a woman gave to her infant, four weeks old, a teaspoonful of hartshorn of the strength of about nine per cent. The child became more and more depressed, and died thirty-six hours after taking the hartshorn. There was no vomiting or purging, and the mouth and fauces presented no excoriation; there was, however, slightly increased redness of the lining membrane. An examination after death was not made.

The salts of ammonia are not often used by persons who are intent upon suicide or murder, but there is one instance on record in which a man was tried for the murder of a child by administering to its spirits of hartshorn. (Regina v. Haydon, Somerset Spring Assizes, 1845.) Of the action of the other compounds of ammonia on man, nothing is known.

Chemical analysis.—The three caustic alkalies, potash, soda, and ammonia, are known from the solutions of the alkaline earths by the fact that they are not precipitated by a solution of carbonate of potash. They all three possess a powerful alkaline reaction on test paper, which, in the case of ammonia, is easily dissipated by heat. Ammonia is immediately known from potash and soda by its odour and volatility. The Sesquicarbonate of Ammonia may be known from other salts by its alkaline reaction, its odour, and its entire volatility as a solid:
from pure ammonia—1, by its effervescing on being added to an acid; 2, by its yielding an abundant white precipitate with a solution of chloride of calcium; — from the carbonates of potash and soda, among other properties,—1, by its giving no precipitate with a solution of the sulphate of magnesia; 2, from the rich violet blue solution which it forms when added in excess to the sulphate of copper; 3, by its odour and volatility.

CHAPTER IX
METALLIC IRRITANT POISONS. ARSENIC—ARSENIous ACID— TASTE—SOLubILITY IN VARIOUS LIQUIDS—SYMPTOMS— CHRONIC POISONING—ANOMALOUS CASES—APPEARANCES AFTER DEATH—QUANTITY REQUIRED TO DESTROY LIFE— PERIOD AT WHICH DEATH TAKES PLACE—TREATMENT. Arsenic. Arsenious Acid.

General remarks.—The term White Arsenic is commonly applied to the arsenuous acid of chemists. Arsenic acid is another compound which is highly poisonous, but has never, so far as I know, been used for the purposes of suicide or murder. Yellow Arsenic, or orpiment, is the sulphuret of chemists. This is also poisonous, apparently because it contains a large portion of arsenuous acid uncombined with sulphur. This often amounts to from fifteen to twenty per cent. of its weight. Orpiment has been, on several occasions, criminally used as a poison. White arsenic, or arsenuous acid, is, however, that preparation which chiefly requires the attention of a medical jurist. In the years 1837–8, there were one hundred and eighty-five cases of poisoning by this substance, the greater number of which were the result of suicide and murder.

Taste of arsenuous acid.—White arsenic is commonly seen under the form of a white powder, or in opaque masses resembling enamel. It is called an acid from its power of combining with alkalies, but it possesses a very feeble acid reaction when dissolved in water. It is often described as having an acid taste, but this does not appear to be correct; a small quantity of it has certainly no appreciable taste, a fact which may be established by direct experiment, and might be inferred from its very sparing solubility. It would appear from numerous cases on record, that it has been unconsciously taken in fatal quantities, in all descriptions of food, without exciting the least sensation on the tongue.
Most of those persons who have been criminally or accidentally destroyed by arsenic, have not been aware of any taste in taking the poisoned substance. In other cases, where the powder has been taken in large quantity, it is described as having had a roughish taste.

Solubility of arsenic.—The solubility of this substance in liquids is a frequent question on trials. The action of water is materially influenced by circumstances. I have found by numerous experiments (Guy’s Hospital Reports, No. 4, p. 81), that hot water in cooling from 210° to 212° on the poison in fine powder, dissolves about the 400th part of its weight. This is in the proportion of nearly one grain and a quarter of white arsenic to about one fluid-ounce of water. Water boiled for an hour on the poison and allowed to cool, holds dissolved the 40th part of its weight, or about twelve grains in one ounce. Cold water allowed to stand for many hours on the poison does not dissolve more than from the 1000th to the 500th part of its weight; i.e. one half grain to one grain of arsenic to nearly one fluid-ounce of water. The presence of organic matter in a liquid renders the poison much less soluble.

Weight of arsenic.—A medical witness is often asked the weight of common or familiar measures of arsenic in powder. I have found a teaspoonful of powdered arsenic to weigh 150 grains,—a tablespoonful to weigh 330 grains,—and a pinch, or the quantity taken up between the finger and thumb of an adult, to weigh 17 grains. These weights are here given as the results of actual experiment: but they are of course liable to some variation.

Symptoms.—These will vary according to the form and dose in which the poison has been administered. The time at which they come on is generally in from half an hour to an hour after the poison has been swallowed. This is the average period. I have known them to appear in a quarter of an hour. Dr. Christison mentions one instance in which the symptoms began in eight minutes; but in the case of Lofthouse, tried at the York Lent Assizes, 1835, the symptoms were proved to have attacked the deceased while he was in the act of eating the cake in which the poison was administered. On the other hand, in an instance communicated to me by Mr. Todd, where one drachm had been taken on an empty stomach, no symptoms appeared for two hours; in one reported by Orfila, the symptoms did not show themselves for five hours; and in another that occurred to Dr. Lachèse, in which a large dose was taken, the symptoms did not come on for seven hours. (Ann. d’Ilyg. 1837, i. 344.) Dr. Thompson, of Liverpool, states that he met with a case in which from thirty to forty grains of arsenious acid, and the same quantity of chrome yellow, were taken. Symptoms of poisoning did not appear until five or six hours afterwards. Recovery was com-
complete in three weeks. Arsenic was detected in the urine. (Med. Chir. Rev., Jan. 1854, p. 294.) There may be every variety between these extremes. In one case their appearance was protracted for ten hours—the maximum period yet known. A very remarkable instance occurred to M. Tonnelier, in which the poison was taken by a young female at eleven o'clock in the morning, and no well-marked symptoms occurred for eight hours: there was then violent vomiting. After death, a cyst, formed of mucous membrane and containing arsenic, was found in the stomach: the poison having thus become sheathed over! (Flandin, i. 535. See on this question the case of Reg. v. Foster, Bury Lent Assizes, 1847.) In an interesting case communicated by Mr. Clegg to the Medical Times (Oct. 21, 1848) symptoms of violent irritation did not show themselves until twenty-three hours after the poison had been taken, and within about half an hour of the death of the patient. The girl was once sick shortly after having taken the poison, but the first symptoms were those of narcotism. The girl was a confirmed opium-ester, and this habit may in some measure have influenced the operation of the poison. From a case communicated to the Medical Gazette by Dr. W. Burke Ryan (lxvii. p. 722), it appears that the active symptoms of irritation which commonly attend arsenical poisoning, may not appear until after the lapse of nine hours from the time at which the poison has been swallowed. With the exception of one case recorded in my work On Poisons (Arsenic), in which the interval was ten hours, this is the longest period of protraction on record. In other instances there have been long intermissions. In all cases in which arsenic enters the system from without, as by its application to the skin, or to ulcerated or diseased surfaces, the symptoms are rarely manifested until after the lapse of several hours.

Their nature.—The individual first experiences faintness, depression, nausea, and sickness, with an intense burning pain in the region of the stomach, increased by pressure. The pain in the abdomen becomes more and more severe; and there is violent vomiting of a brown turbid matter, mixed with mucus, and sometimes streaked with blood. These symptoms are followed by purging, which is more or less violent; and this is accompanied by severe cramps in the calves of the legs. The matters discharged from the stomach and bowels have had in some instances a yellowish colour, as it was supposed, from a partial conversion of the poison to sulphuret, but more probably from an admixture of bile. The vomited matters are in some cases coloured by blood,—and the mixture of blood with bile has often given to them an olive green or brown colour. In other cases, they may consist of a large quantity of mucus ejected in a flaky state and having a milky-white appearance, as if from the admixture of white arsenic. The colour of the vomited
matters has been hitherto much relied on as an aid to diagnosis; but it is necessary to direct the attention of practitioners to the probable effect of the law on the sale of arsenic (14 Vic. cap. 13. sec. 3) in completely changing the appearance of the matters vomited by a person labouring under the effects of this poison. The sale of white arsenic in any quantity less than ten pounds is prohibited, unless it be mixed with 1-16th part of its weight of soot, or 1-32d part of its weight of indigo. The vomited matters may therefore be blue or black,—or the admixture of bile may render them of a deep green colour. In a case of arsenical poisoning communicated to me by Dr. Maclagan, the blue vomiting at first completely misled those who were called to render assistance. As soot and indigo are both insoluble in water, these substances will be slowly deposited from the vomited matters by subsidence, and the colour given by blood or bile may then become perceptible.

The vomiting is in general violent and incessant, and is excited by any liquid or solid taken into the stomach. There is tenesmus (straining), and the discharges by the bowels are frequently tinged with blood. There is a sense of constriction, with a feeling of burning heat in the throat, commonly accompanied by the most intense thirst. The pulse is small, very frequent, and irregular; sometimes wholly imperceptible. The skin is cold and clammy in the stage of collapse; at other times it is very hot. The respiration is painful from the tender state of the abdomen. Before death, stupor sometimes supervenes, with paralysis, tetanic convulsions, or spasms in the muscles of the extremities. In one instance trismus (lock-jaw) appeared in three quarters of an hour. (Orfila, i. 449.) Such is the ordinary character of the symptoms in an acute case of arsenical poisoning, i.e. where from half an ounce to an ounce of the poison has been taken.

Chronic poisoning. — Should the person recover from the first effects, and the case be protracted, or should the dose have been small and frequently administered, there will be inflammation of the conjunctiva, with suffusion of the eyes, and intolerance of light; — a condition which is, however, often present with the early symptoms above described. In a case reported by Mr. Jeffreys, an adult female died in three hours after taking arsenic in a pudding served at dinner. There was no vomiting or purging. In two hours she was in a state of complete collapse, and at this time it was noticed that the conjunctiva (the membranes of the eyes) were red. (Med. Times, Aug. 30, 1851, p. 229.) There is also irritation of the skin, accompanied by a vesicular eruption, which has been called eczema arsenicale. Sometimes this has assumed the form of nettle-rash or of the eruption attending scarlet fever, for which disease arsenical poisoning has been mistaken. Local paralysis, preceded by numbness or tingling in the fingers and toes, and other symptoms
of nervous disorder, are also very common consequences. Exfoliation of the cuticle and skin of the tongue, with the falling off of the hair, has likewise been witnessed. (Case of the *Turners*, 1815, Marshall, 119.) Salivation has been observed to follow, especially when small doses of the poison have been given for a length of time. (Med. Gaz., xvi. 790.) Strangury and jaundice have been noticed among the secondary symptoms. (Marshall on Arsenic, 44, 111.) A well-marked case of slow poisoning by arsenic is recorded by Flandin. (Traité des Poisons, ou Toxico-logie, Tom. i. p. 510.) It illustrates a not unfrequent form of secret murder, and it is well calculated to inspire caution in making a diagnosis from symptoms. A woman put daily into the soup of her fellow-servant, a very small quantity of arsenious acid in powder. Shortly after dinner this person was seized with vomiting, which led to the rejection of the food and poison before the latter had caused any serious mischief. As this practice was continued for about six weeks, the stomach became exceedingly irritable; there was pain in the bowels, and the woman became much emaciated. There was also spitting of blood, with such a degree of nervous irritability, that a current of air falling upon her, caused an attack of spasms and convulsions. When the patient found that she could not bear any thing on her stomach, she left the place and passed two months in the country. Her health became gradually re-established there, and she returned to resume her usual occupations. The prisoner, however, renewed her attempts; and to make sure of destroying life, gave her one morning in coffee, a strong dose of arsenious acid in powder; violent vomiting ensued, and the poison was expelled with the food taken at breakfast. Arsenic was detected in the vomited matter, and the explanation of the cause of the long previous illness then became clear. Under proper treatment the patient recovered. I believe this mode of poisoning to be more frequent in this country than is commonly supposed; and it behoves practitioners to be exceedingly guarded in their opinions, for the usual characters of arsenical poisoning are completely masked. The case of Mrs. Wooler (Durham Winter Assizes, 1855) conveys an important lesson in this respect. The suspicions of the medical attendants were confirmed, but at too late a period to save the life of the lady. The symptoms may be easily referred to chronic inflammation, or ulceration of the stomach from natural causes, leading to perforation. Some years since I was required to examine a case like that of Wooler, in which the death of a person had been caused by his housekeeper under somewhat similar circumstances. The crime was not discovered until after the lapse of two years; and from the small dose given, and repeated vomiting during life, no arsenic could be detected in the body. There are many anomalous cases on record, in which the symptoms have diverged so much from the ordinary course as to
embarrass medical practitioners. For some of these, I must refer to a paper by Dr. Ogston, Med. Gaz., Vol. xlvii. p. 181; also to my work On Poisons, p. 320.

There is one form of chronic poisoning by arsenic on which it will be proper to make a few remarks, as the real cause may remain wholly unsuspected. Arsenic is largely employed in this country, under the form of Scheele's green or arsenite of copper, in the manufacture of decorative papers with which the walls of sitting, and bedrooms are covered. Some persons have suffered from symptoms of chronic poisoning by arsenic, in which no other cause was apparent than the continued respiration of the air of their rooms, charged probably at times with a fine arsenical dust. During the present year several cases of this kind have come to my knowledge. On examining the papers, I have found them in some instances loaded with arsenic, laid on in a rough and coarse manner, so as to be easily removable by friction. Arsenic is thus used in imparting a green tint to some of the most costly as well as the cheapest decorative papers. It is a practice fraught with danger in more respects than one, and under a proper system of medical police, it would not be permitted. In the kingdom of Prussia, the use of these papers is strictly prohibited. If there has not hitherto been much complaint on the subject, it may be attributed to the fact that the cause has not been suspected. Many obscure cases of illness referred at the time to constitutional or other causes, may probably have been due to the effects of arsenical dust thus inhaled day and night by those who inhabited the rooms. Dr. Hinds has described two cases in which the prominent symptoms were prostration of strength, headache, thirst, loss of appetite — an inflammatory state of the conjunctivae with heat and dryness of the fauces. (Med. Times and Gazette, May 23, 1857, p. 521.) A portion of the paper of the room in which these persons lived was sent to me, and on examination I found in the green pigment spread over it, a large quantity of arsenic. These facts should be borne in mind in cases in which it is suspected that poison is being secretly administered to another.

Appearances after death. — The striking changes produced by arsenic are generally confined to the stomach and bowels. They are commonly well marked in proportion to the largeness of the dose and the length of time which the individual has survived after taking the poison. Our attention must be first directed to the stomach. Arsenic seems to have a specific effect on this organ: for, however the poison may have entered into the system — whether through a wounded or ulcerated surface, or by the act of deglutition — the stomach has been found inflamed. Inflammation of this organ cannot, then, be always considered to depend on the local irritant action of the poison on the stomach.

The mucous membrane of the stomach, which is often covered with a layer of mucus, mixed with blood, and with scattered...
white pasty-looking patches of arsenious acid, is commonly found red and inflamed: the colour, which is sometimes of a dull or brownish red, becomes brighter on exposure to the air: at other times it is of a deep crimson hue, interspersed with black-looking lines or patches of altered blood. The redness is usually most strongly marked at the greater extremity; in one case it may be found spread over the whole mucous surface, giving to it the appearance of red velvet, in another it will be chiefly seen on the prominences of the rugae. Blood of a dark colour is effused in various parts within the folds, or beneath the lining membrane, — an appearance which has been mistaken for gangrene. [On this point see the case of the Queen against Durand Spry, C.C.C., August 28, 1848: also Med. Gaz., Nov. 24, 1848.] The stomach often contains a mucous liquid of a dark colour tinged with blood. The coats are sometimes thickened in patches, being raised up into a sort of fungous-like tumour, with arsenic imbedded in them: at other times they have been found thinned. The mucous membrane is rarely ulcerated, and still more rarely gangrenous. Perforation of the coats is so uncommon a result of arsenical poisoning, that there are only three clear instances on record. In a case recently examined by M. Chevalier, the stomach of a person who had died from the effects of arsenic was found perforated at the larger end. The aperture is described to have been of the size of a franc piece, round, soft, and somewhat thickened in its margin. There was no vascularity or sign of erosion about it, nor was there any appearance of ulceration on the other parts of the mucous membrane. Externally the stomach was covered with false membranes arising from inflammation of the peritoneum. (Ann. d’Hyg. 1852, i. 448.) This case is so imperfectly reported that it is impossible to say whether the perforation was caused by arsenic, or whether it was the result of other morbid changes. The mucous glands of the stomach have been found enlarged; but this is by no means an unusual morbid appearance from any cause of local irritation, without reference to poisoning. Various morbid appearances are said to have been met with in the lungs, heart, brain, and urinary organs; but they do not appear to be characteristic of arsenical poisoning. It is undoubtedly to the stomach and intestines that a medical jurist must look for the basis of medical evidence in regard to appearances after death.

Period required for inflammation.—A witness is often asked in a Court of law how long a time is required after the taking of arsenic, for the production of these well-marked appearances in the stomach, especially of inflammation of the mucous membrane. In three cases communicated to me by Mr. Foster, of Huntingdon, death occurred in one, a child, at the end of two hours; in the second, an adult, at the end of three hours and a half; and in the third, after the lapse of about six hours. In each of these the
stomach was found highly inflamed, and, in the one that proved fatal in two hours, the mucus membrane had a vermilion hue. This last I believe to be the shortest period at which inflammation of the stomach from the effects of arsenic has been met with.

_Period required for ulceration._—Another question put to a witness may be this,—What period of time is required for ulceration of the mucus membrane to take place, as an effect of this poison? If arsenic has destroyed life with unusual rapidity and the stomach is found ulcerated, an attempt may be made to refer this ulceration to some other cause. Such an attempt was made in the case of Rhymes, which was the subject of a criminal trial in 1841. (Guy’s Hospital Reports, Oct. 1841, p. 283.) I found ulceration of the mucus membrane, which had been completely removed in patches, although the deceased had survived the effects of the poison only ten hours. The deposition of the arsenic in and around the ulcers, as well as the appearance of recent inflammation about them, left no doubt that they had been produced by the poison, and were not owing to previous disease, as urged in the defence. Dr. Christison mentions a case observed by Mr. Hewson, in which many eroded spots were found on the stomach, although the person died from the effects of arsenic in five hours. (On Poisons, p. 340.)

Absence of inflammation._—Are the stomach and intestines always found inflamed in cases of poisoning by arsenic? The answer must be decidedly in the negative. At the trial of M’Crachen, at the Derby Autumn Assizes, in 1832, for killing his wife with arsenic, the fact of poisoning was clearly established, and a large quantity of arsenic was found in the stomach of the deceased, but there was no appearance of inflammation, either in that organ or in the intestines. The two following cases are recorded in Rust’s Magazine:—A servant girl had some arsenic administered to her in chocolate. She was seized with nausea and violent pain in the stomach, and died the same evening. On inspection, there was no remarkable vascularity or inflammation of the stomach;—but arsenic was found in the duodenum. A man was taken ill with vomiting and violent pains in the abdomen after partaking of some soup, and he died from symptoms of poisoning. On inspection the mucus surface of the stomach presented no morbid change, with the exception of a slight redness about the entrance of the gullet. Arsenic was found in the contents of the intestines. In two cases of poisoning by arsenic which I have had an opportunity of examining, the mucus membrane was pale, and in one of these the coats were much thickened, presenting almost a gelatinous condition.

In a few instances the mouth, pharynx, and oesophagus have been found inflamed, but in general there are no changes in these parts to attract particular attention. The mucus membrane of the small intestines may be found inflamed throughout, but
commonly the inflammatory redness is confined to the duodenum, especially to that part which joins the pylorus. Of the large intestines the rectum appears to be the most prone to inflammation. The heart, brain, and lungs present no appearances which can be considered characteristic of arsenical poisoning. The same remark applies to the liver, spleen, and kidneys, although these, like the other soft organs, may become receptacles of the absorbed poison. It is worthy of observation in relation to the known antiseptic properties of arsenic, that the parts especially affected by the poison (the stomach and intestines) occasionally present the well-marked characters of irritant poisoning for a long time after death. In two cases (Chesham) referred to me by Mr. Lewis, coroner for Essex, a deep red inflammatory appearance of the mucous membrane immediately below a layer of sulphuret of arsenic was well marked, although the bodies had been buried nineteen months. In a case which occurred in March 1848, the stomach was also well preserved: and it retained an inflammatory redness after the lapse of twelve months. Absorbed arsenic does not, however, appear to prevent the decomposition of the soft organs in which it is deposited. For a summary of the appearances caused by arsenic, and its influence in modifying putrefactive changes, I must refer the reader to a paper by Dr. Geoghegan (see Medical Gazette, Vol. xlvii. pages 171 and 218, and Observations on Arsenical Poisoning, Dublin Quarterly Journal, Feb. 1851).

Quantity required to destroy life.—This is an important medico-legal question. According to a case quoted by Dr. Christison, the smallest fatal case on record, in an adult, is stated to have been thirty grains of the powdered white arsenic: the man died in six days. But undoubtedly a much smaller quantity than this will destroy life. Dr. Lachèse states that a dose of from one to two grains may act fatally in a few days:—this, however, is a speculative statement. (Ann. d’Hyg. 1837, i. 334.) It is highly probable that this dose would prove fatal to a child, or to weak and debilitated persons. The smallest fatal dose hitherto recorded was observed in a case communicated by Dr. Castle, of Leeds, to the Provincial Journal (June 28, 1848, page 347). A woman took half an ounce of Fowler’s solution (Arsenite of Potash) in unknown doses, during a period of five days. She then died: and on examination, the stomach and intestines were found inflamed. Death took place by syncope (mortal fainting), and there was an absence of vomiting and purging. The quantity of arsenic which here destroyed life could not have been more than two grains. In another case, two grains and a half of arsenic, contained in two ounces of Fly-water, killed a robust healthy girl, aged nineteen, in thirty-six hours. (See Med. Gaz., Vol. xxxix. p. 116.) Hence a medical witness will be justified in stating that under circumstances favourable to its
operation, the fatal dose of this poison in an adult is from two to three grains.

Period at which death takes place.—Some remarks on the important bearing, which an answer to this question may have in a case of arsenical poisoning, have been elsewhere made (ante, p. 19). From the numerous well-observed cases, which are now on record, it would appear that large doses of arsenic commonly prove fatal in from eighteen hours to three days. Probably, the average time at which death takes place is twenty-four hours; but the poison may destroy life within a much shorter period than this. There are now many authentic cases reported, in which death has occurred in from three to six hours. In 1845 I met with a well-marked case of death from arsenic in five hours, and in another, which occurred in April, 1849, death took place in two and a half hours. (Guy's Hospital Reports, Oct. 1850, 183. See also Ann. d'Hyg. 1837, i. 839.) It is singular that a few years since observations were so limited that it was thought to be impossible that arsenic could destroy life in a shorter period of time than seven hours (see ante, p. 19, Russell's case); and this rapidity of death was actually considered as a medical fact, which in some measure tended to negative the allegation of death from arsenic! One of the most rapidly fatal cases on record I believe to be that which occurred to Mr. Foster of Huntington. This gentleman satisfactorily ascertained that the subject, a child under three years of age, died within two hours from the effects of arsenic. The quantity taken could not be determined; but the time at which death takes place is by no means dependent on the quantity of poison taken. Dr. Borland, who formerly attended my lectures, communicated to me a case in which death probably occurred in less than two hours. An interesting case has been published by Dr. Dymock. A girl, aged twenty, took two ounces of powdered arsenic, and died in less than two hours and a half. There were no comatose symptoms:—the girl was sensible to the last, and she had vomited violently. The mucous membrane of the stomach was covered with bright patches of a scarlet colour. (Ed. Med. and Surg. Journ., April, 1843.) In some instances death does not occur until long after the average period. In one case in which an adult swallowed about half an ounce, death did not take place for fifty hours, and it is remarkable that there was an entire absence of pain (Med. Gaz., Vol. xlvi. page 446). In the case of the Duke de Praslin, one large dose was taken, but death did not occur until the sixth day. (Ann. d'Hyg. 1847, ii. 367.) In October 1847, a man who had swallowed 220 grains of arsenic was admitted into Guy's Hospital. He died on the seventh day. It is obvious that a patient who recovers from the first effects of this poison may still die from exhaustion or other secondary causes many days or weeks after having taken it.
In the case of *Reg. v. M'Cormick*, Liverpool Winter Assizes, the child died, as it appeared, from one dose of arsenic, after the lapse of twelve days. (Med. Gaz., xxxiii. 434.) The child partially recovered from the first effects. In the case of *Dr. Alexander* death took place on the sixteenth day. (Med. Times and Gazette, April 18, 1857, p. 389.)

In one instance arsenic was applied externally to the head, and the person did not die until the twentieth day. The longest duration of a case of poisoning by arsenic which I have met with is reported by Belloc. A woman, aged 56, employed a solution of arsenic in water to cure the itch, which had resisted the usual remedies. The skin became covered with an erysipelatous eruption, and the itch was cured, but she experienced severe suffering. Her health gradually failed, and she died after the lapse of two years, having suffered during the whole of this period from a general tremor of the limbs. (Cours de Méd. Lég., 121.)

**Chemical analysis.** — *Arsenic as a solid.* — In the simple state, *white arsenic* may be identified by the following properties: —

1. A small quantity of the powder, placed on platina foil, is entirely volatilised at a gentle heat (370°) in a white vapour. Should there be any residue, it is impurity; sometimes plaster of Paris or chalk is found mixed with it. The quantity of fixed impurity present may in this way be easily determined. If a small portion of the white powder be very gently heated in a glass tube of narrow bore, it will be sublimed without melting, and form a ring of minute octahedral crystals, remarkable for their lustre and brilliancy. Under a microscope of high magnifying power (250 diameters) the appearance of these crystals is remarkably beautiful and characteristic: one not exceeding the 4,000th of an inch in size may be easily recognised by the aid of this instrument. It will be observed in these experiments, that white arsenic in vapour possesses no odour.

2. On boiling a small quantity of the powder in distilled water, it is not dissolved, but it partly floats in a sort of film, while a part becomes aggregated in small lumps at the bottom of the vessel. It requires long boiling, in order that it should become dissolved and equally diffused through water.

3. When the powder is treated with a solution of hydro-sulphuret of ammonia in a watch-glass, there is no change of colour, as there is with most metallic poisons: on heating the mixture, the white powder is dissolved; and on continuing the heat until the ammonia is expelled, a rich yellow or orange-red film is left (sesqui-sulphuret of arsenic), which is soluble in all alkalis, and insoluble in muriatic acid.

**Reduction-process.** — When a small portion of the powder, i.e. from one-fourth to one-twentieth part of a grain, is heated with some reducing agent containing carbon (and the best substance for this purpose is soda-flux) obtained by incinerating asbest or
THE REDUCTION PROCESS.

tartrate of soda in a close vessel) in a glass tube about three inches long and one-eighth of an inch in diameter, it is decomposed: a ring of metallic arsenic of an iron-grey colour is sublimed and deposited in a cool part of the tube. At the same time there is a perceptible odour, resembling that of garlic, which is possessed by metallic arsenic only, while passing from a state of vapour to arsenious acid. This odour was at one time looked upon as peculiar to arsenic, but no reliance is now placed on it as a matter of medical evidence—it is a mere accessory result. In this experiment of reduction, there are commonly two rings deposited in the tube:—the upper ring has a brown colour, and appears to be a mixture of finely divided metallic arsenic and arsenious acid. In order to determine the weight of the sublimate, the glass tube should be filled off closely on each side of the metallic ring, and weighed; the sublimate may then be driven off by heat, and the piece of glass again weighed:—the difference or loss represents the weight of the sublimate. These sublimates are remarkably light, and require to be weighed in a delicate balance. I found, in one experiment, a large sublimate to weigh no more than 0.08 grain. By heating gently the piece of tube, reduced to powder, in another tube of larger diameter, the metallic arsenic, during volatilisation, forms octahedral crystals of arsenious acid, which may be dissolved in a few drops of water, and tested by one or more of the liquid reagents. The metallic sublimate, or the crystals produced from it, may be subjected to the following process, in order to determine their real nature:—Break the glass on which the sublimate is deposited into fragments, and digest these in a few drops of strong nitric acid. The sublimate, if due to arsenic, is thereby converted to arsenic acid. The acid solution should be evaporated to dryness; the white uncrystalline residue dissolved in a few drops of distilled water, and a solution of nitrate of silver added. A brick-red precipitate indicates arsenic acid, and thus proves incontestably that the sublimate was of an arsenical nature.

Objections to the Reduction-process. — 1. The glass itself may acquire a black metallic lustre by heat from the reduction of the oxide of lead contained in it. This takes place when the tube is held too much in the body of the spirit-lamp flame instead of over the point. This metallic stain differs in appearance from arsenic; it is fixed, while the arsenical sublimate is volatile by heat, and convertible to white octahedral crystals of arsenious acid. 2. Charcoal may give a dark colour to the tube, but it is not advisable to employ this substance unless the quantity of arsenious acid is very minute; besides, the stain of charcoal is fixed, and has no metallic lustre like that of arsenic. 3. Arsenic is said to be contained in glass, and it was supposed that it might be sublimed by heat; this, however, is impossible; arsenic is sometimes used in the manufacture of transparent glass, but it is entirely
volatilised during the process. (See Ann. d’Hyg. 1834, i. 224; also Galtier, Toxicologie, i. 297.) I have frequently examined large quantities of the glass tubing employed by chemists in a finely powdered state, without finding the slightest trace of arsenic. Arsenic is, however, contained in some kinds of opal glass. 4. Cadmium is a metal which is said to form a metallic sublimate like arsenic. The brown oxide of cadmium may be reduced by a similar process, but the metallic sublimate is wholly different from that of arsenic; it has a tin-like lustre, and is generally fringed with a brown margin of reproduced oxide. There is no odour of garlic during the reduction of oxide of cadmium; and, on heating the metallic ring, it is not wholly volatilised like arsenic, but converted to a ring of brown oxide. 5. Mercury forms a sublimate, but in white silvery globules, quite distinct from the dark iron-grey lustre of arsenic. Neither antimony nor zinc can be volatilised from any of their preparations in a metallic state, by the heat of a spirit-lamp. The process of reduction, with the most simple precautions, is, therefore, when thus applied, conclusive of the nature of the substance under examination. Any doubt respecting the nature of a sublimate may be removed by a careful microscopical examination. It is advisable, although not absolutely necessary, that we should apply the three foregoing tests to the white powder, before attempting to extract the metal from it.

Arsenic in solution in water; Liquid tests.—The solution is clear, colourless, possesses scarcely any perceptible taste, and has a very faint acid reaction. In this state, we should first evaporate slowly a few drops on a glass plate, when a confused crystalline crust will be obtained. On examining this crust with a common lens, it will be found to consist of numerous minute octahedral crystals, presenting triangular surfaces by reflected light. By this simple experiment, arsenic is distinguished from every other metallic poison.

1. Silver-test.—On adding to the solution Ammonio-nitrate of silver, a rich yellow precipitate of arsenite of silver falls down; rapidly changing, under exposure to daylight, to a greenish-brown colour. The test is made by adding to a very strong solution of nitrate of silver, a weak solution of ammonia, continuing to add the latter, until the brown oxide of silver, at first thrown down, is almost re-dissolved. The yellow precipitate is soluble in nitric, tartaric, citric, and acetic acids, as well as in caustic ammonia. It is not dissolved by potash or soda.

2. Copper-test.—On adding to the solution of arsenic Ammonio-sulphate of copper, a rich green precipitate is formed, the tint of which varies according to the proportion of arsenic present, and the quantity of the test added: hence, if the quantity of arsenic be small, no green precipitate at first appears; the liquid simply acquires a blue colour from the test. In less than an
hour, if arsenic be present, a bright green deposit is formed, which
might be easily separated from the blue liquid by filtration. This
test is made by adding ammonia to a weak solution of sulphate
of copper, until the bluish-white precipitate, at first produced, is
nearly re-dissolved: it should not be used in large quantity if con-
centrated, as it possesses a deep violet blue colour, which com-
pletely obscures or conceals the green precipitate formed. The
precipitated arsenite of copper is soluble in all acids, mineral and
vegetable, and in ammonia, but not in potash or soda. When
dried and collected, it possesses this characteristic property:—
by very slowly heating a few grains in a tube of small bore,
arsenious acid is sublimed in a ring of minute resplendent octa-
hedral crystals, oxide of copper being left as a residue.

3. Sulphuretted hydrogen test.—The hydro sulphur et of am-
onia gives no precipitate in a solution of arsenic until an acid
has been added, whereby arsenic is known from most metallic
poisons. On adding an acid (acetic or dilute hydrochloric free
from arsenic), a rich golden yellow-coloured precipitate is thrown
down (orpiment or sulphuret of arsenic). It is better, however,
to employ in medico-legal analysis, a current of washed sulphu-
retted hydrogen gas, which is easily procured by adding to sul-
phuret of iron in a long-necked bottle a mixture of one part of
strong sulphuric acid and three parts of water. The arsenical
liquid should be slightly acidulated with pure diluted muriatic
acid, before the gas is passed into it: at least, care should be
taken that it is not alkaline. The yellow compound is immediately
produced if arsenic be present, and may be collected after boiling
the liquid sufficiently to drive off any surplus gas. The precipi-
tation is likewise facilitated by adding to the liquid a solution
of muriate of ammonia. This yellow precipitate is known to be
sulphuret of arsenic by the following properties:—1. It is in-
soluble in water, alcohol, and other, as well as in all acids, mineral
(muriatic) and vegetable; but it is decomposed by strong nitric and
nitro-muriatic acids. 2. It is immediately dissolved by caustic
potash, soda, or ammonia; forming, if no organic matter be pre-
sent, a colourless solution. 3. When dried and heated with three
parts of soda-flux, or with an equal part of cyanide of potassium,
it furnishes a metallic sublimate of arsenic. This last experiment
requires a little care, as some sulphur is apt to be sublimed, and
obscure the results. If fine pulverulent silver be used as the
reducing agent, and the heat gently applied, the arsenic may be
evolved at once from the sulphuret, in a ring of octahedral crystals
of arsenious acid. 4. The arsenical nature of the yellow pre-
cipitate may be also conclusively proved by heating it with a
mixture of one part nitric and two parts hydrochloric acid, and
evaporating to dryness. A residue of arsenic acid is thus ob-
tained, which, when dissolved in a few drops of distilled water,
and tested by nitrate or ammonio-nitrate of silver, yields a brick-
red precipitate of arseniate of silver. Unless two or more of these properties are proved to be possessed by the yellow precipitate formed by sulphured hydrogen in an unknown liquid, it cannot be a compound of arsenic; and it would not be safe as a general rule to receive evidence on the point. On the other hand, when these properties (especially 3 and 4) are possessed by the precipitate, it must be arsenic, and can be no other substance.

Objections.—Many objections have been taken on criminal trials to the medical evidence, founded on the application of these tests individually; but it may be safely averred that there is no substance except arsenic which will give the reactions with the three. It is customary for toxicologists to lay down the rule, that the objection urged against one test for arsenic is removed by the application of the other tests. In a criminal case in which I was required to give evidence (Reg. v. Jennings, Berks Lent Ass. 1845), it was ingeniously suggested in the defence, that there might perchance be such a mixture of substances not containing arsenic, as to affect all the tests like arsenic when separately applied. This, however, is clearly a chemical impossibility, for it would require the mixture of substances incompatible with each other. But a mere change of colour, or even the production of a coloured precipitate on adding a test to an unknown liquid, furnishes no evidence, unless the properties of the precipitate be those of an arsenical compound.

Again, no conceivable mixture of substances would produce a metallic ring resembling that of arsenic, so as to deceive an analyst experienced in such matters; and far less a ring, possessing those properties of an arsenical sublimate, which it would be easy for one who may have had but little experience, to determine by simple chemical processes.

Marsh's process. Hydrogen test.—The action of this test depends on the decomposition of arsenious acid and its soluble compounds, by hydrogen evolved in the nascent state from the action of diluted sulphuric acid on zinc. The apparatus is of the most simple kind, and is so well known as to need no description. The arsenic may be introduced into the short leg of the tube in the state of powder; but it is far better to dissolve it in water, by boiling, either with or without the addition of a few drops of caustic potash. The metallic arsenic combines with the hydrogen, forming arsenured hydrogen gas, which possesses the following properties:—1. It burns with a bluish-white flame, and thick white smoke (arsenious acid). 2. A cold plate of glass or white porcelain held in the flame near the point, receives a dark stain from the deposit of arsenic upon it. This stain is composed in the centre of pure metallic arsenic, which (as it is formed on glass) may be sometimes raised up in a distinctly bright leaf of metal,—immediately on the outside of this is an opaque black ring (sulphide or hyduret of arsenic), which, when viewed by transmitted light, is of a clear hair-brown colour at the extreme
edge. If the quantity of arsenic be small, the metallic lustre and opacity may be wanting, and the whole stain will have a brown colour by transmitted light. On the outside of this black ring, is a thin wide film of a milk-white appearance, which is nothing more than arsenious acid reproduced by combustion. 3. A white cancer or a slip of card or paper moistened with ammonio-nitrate of silver, held about an inch above the point of the flame, will be found, if arsenic be present, to be coloured yellow, from the reproduced arsenious acid being absorbed, and forming yellow arsenite of silver, easily soluble in acetic acid and ammonia. 4. Nitrate of silver on paper is immediately blackened and reduced by the unignited gas. Unless the gas possess these properties, there is no certain evidence of the presence of arsenic in the liquid examined.

Objections to Marsh’s process.—Other substances will combine with hydrogen, and when the gas is burnt, a deposit will be formed on glass which may be mistaken for arsenic. The only objection of any practical force is that founded on the presence of antimony. There are these differences between the arsenical and antimonial deposits: the deposit of antimony has rarely the bright metallic lustre which that of arsenic commonly presents; by transmitted light it is of a smoky black, while that of arsenic is of a hair-brown colour. Although the antimonial is very similar in colour to the arsenical flame, yet the third property is entirely wanting. If the ammonio-nitrate of silver be held over the antimonial flame, the silver is reduced; no yellow arsenite is formed, as in the case of arsenic. This last criterion distinguishes the arsenical flame from that produced by all other combustible gases. The arsenical deposit may be further distinguished by dissolving it in nitric acid, evaporating to dryness, and adding nitrate of silver. A brick-red precipitate is formed if the stain have been caused by arsenic.

Arsenic is frequently contained as an impurity in zinc and sulphuric acid; hence the purity of the materials employed must be determined before any reliance can be placed on the results.

Reisch’s process.—In the application of this process, the liquid suspected to contain arsenic, or the solid dissolved in distilled water, is boiled with about one-sixth part of pure muriatic acid (proved to be free from arsenic), and a small slip of bright copper foil or copper gauge is then introduced. If arsenic be present, even in small quantity, the copper acquires either immediately or within a few minutes a dark iron-grey coating from the deposit of this metal. This is apt to scale off, if the arsenic be in large quantity, or if the liquid be long boiled. We remove the slip of copper, wash it in water, dry it, and gently heat it in a reduction-tube, when arsenious acid will be sublimed in minute octahedral crystals: if these should not be apparent from one piece of copper, several may be successively introduced. A
large surface of copper foil or copper gauze may be in this way at once covered. This process succeeds perfectly with powdered arsenic, the arsenites, arsenic acid, the arseniates, and orpiment; but, as it has been shown by Dr. Rainey, its operation is not so delicate or certain with arsenic acid and the arseniates as with the other compounds of arsenic. When the quantity of arsenic is small, the polished copper merely acquires a faint violet or bluish tint, and the deposit is materially affected by the quantity of water present, or, in other words, the degree of dilution. But one great advantage is, that we are not obliged to dilute the liquid in the experiment, and there is no material loss of arsenic, as in the hydrogen process—the whole may be removed and collected by the introduction of successive portions of copper. This process is extremely delicate, the results are very speedily obtained, and are highly satisfactory. Among the cautions to be observed are these: 1. not to employ too large a surface of copper in the first instance; and 2. not to remove the copper from the liquid too soon. When the arsenic is in minute quantity, and the liquid much diluted, the deposit does not take place sometimes for half an hour. If the copper be kept in for an hour or longer, it may acquire a dingy tarnish from the action of the acid only. This is known by its want of metallic lustre, and its being easily removed by friction, as well as by its yielding no crystalline sublimate when heated.

Objections to Reinsch’s process.—Certain objections have been urged to this process. Thus arsenic may be present in the muriatic acid: this is at once answered by boiling the copper in a mixture of the muriatic acid and water before adding the suspected liquid. This should always be a preliminary experiment. In the case of Mrs. Wooler (Durham Winter Assizes, 1855), some doubt was thrown on the scientific evidence by reason of the use of arsenical muriatic acid. The discovery of the impurity was not made until after the analysis was completed. Another objection is, that other metals are liable to be deposited on copper under similar circumstances. This is the case with Antimony, whether in the state of chloride or of tartar-emetic; and it is not always possible to distinguish by the appearance the antimonial from the arsenical deposit. Should the quantity of antimony be small, the deposit is of a violet tint; if large of an iron-grey colour, resembling arsenic. There is one answer to these objections, namely, that from the arsenical deposit, octahedral crystals of arsenious acid may be procured by slowly heating either the slip of copper, or the grey deposit scraped from it, in a reduction-tube. If this experiment be carefully performed, a ring of white arsenious acid will be easily obtained; this may be examined by the microscope for crystalline octahedra, and afterwards boiled in a few drops of water, and the solution tested with the ammonio-nitrate of silver and sulphuretted hydrogen. When
the sublimates are too small for such a solution and subdivision, they may be converted to arsenic acid, by digestion in nitric acid, by the process already described (ante, page 75), and the residue tested for arsenic acid by nitrate of silver. Such a corroborative operation is necessary, because the crystalline form of arsenious acid is not always distinguishable by the eye; and the antimonial deposit gives a white amorphous sublimate, which, however, is quite insoluble in water. Care must be taken not to mistake minute spherules of water, mercury, or muriatic acid for detached crystals of arsenious acid; and here the microscope will be found of great service. The facility of applying Reinsch's process renders it necessary that the experimentalist should be guarded in his inferences. It is not merely by the production of a deposit on copper that he judges of the presence of arsenic; but by the conversion of this deposit to arsenious acid, demonstrable by its crystalline form and its chemical properties. If a deposit take place on copper, and arsenious acid cannot be obtained by heating it, then the evidence of its having been caused by arsenic is insufficient. Owing to the neglect of these corroborative results, antimony and other substances have been occasionally mistaken for arsenic.

**Arsenic in liquids containing organic matter.**—Arsenious acid, when in a state of solution, is not liable to be precipitated by any animal or vegetable principles, although such substances render it less soluble in water. It has been announced that arsenic enters into combination with albumen, but this is a point of no practical importance in reference to the present subject of inquiry. The liquid for analysis should be filtered through muslin, cotton, or paper, in order to separate any insoluble matters; these should be well pressed and drained. Should the liquid be coloured, this is of little moment, provided it be clear. If viscid, it should be diluted with water and boiled with a small quantity of muriatic acid; on standing, a deposit may take place, and this should be separated by a filter. As a trial-test, we may now boil in a portion of the liquid, strongly acidulated with pure muriatic acid, a slip of copper-gauze, or introduce into it a piece of fine copper wire highly polished. In a few seconds, if arsenic be present, the copper will acquire a violet blue or grey metallic coating. If, after half an hour, the copper remain unchanged, the arsenic, if present, must be in extremely minute proportion; if, on the other hand, the copper be covered by a grey deposit, it should be dried and heated in a reduction-tube in the way already described, in order to obtain from it octahedral crystals of arsenious acid, the nature of which must be subsequently demonstrated by the special mode of examination already pointed out. By means of several such slips of copper-gauze, i.e. very finely woven copper wire, a quantity of metallic arsenic may be separated, sufficient, on reconversion to
arsenious acid, to allow of a solution in water being made, to which all the liquid tests may be applied. If the quantity thus procured be small, the arsenious acid may be converted to arsenic acid by nitric acid (see p. 75). Unless a brick-red precipitate result, under due precautions, on the addition of nitrate of silver, we cannot be certain that the sublimate was owing to arsenic. One obstacle to the use of copper-gauze is, that oily, and other kinds of organic matter, not easily removable by washing in water, may adhere to it. These substances are liable to be sublimed by heat, and obscure the arsenic:—but they may be easily removed by warming the gauze, first in alcohol, secondly in ether, and then in water, taking care to dry it thoroughly before heat is applied to it. When, however, much oily matter is present, it is better to boil the organic substance with muriatic acid, and filter the liquid through a wet filter before introducing the copper-gauze. In this way the fat and solid organic impurities may be separated. An even coating of arsenic was by this process obtained on copper-gauze from the decomposed tissue of the stomach of a person whose body had been buried nearly two years. As the gauze, from its extreme fineness, is remarkably hygrometric, it requires to be thoroughly dried in a vapour-bath or in a current of warm air before it is submitted to heat in a reduction tube. Should there be any doubt whether the sublimate be caused by spherules of liquid or particles of arsenic, it will be advisable to examine it by a good microscope under a power of one hundred and forty diameters. If arsenic, it will present itself in minute detached angular crystals, having triangular surfaces, and more or less of an octahedral form. Globules of water, or of hydrochloric acid present themselves in rounded or oblong spots, transparent in the centre, and dark at the circumference. Spherules of mercury are perfectly opaque, and have a metallic lustre by reflected light. These foreign substances may thus be seen among, and easily distinguished from, the crystals of arsenic, in ordinary sublimates. In a fine sublimate, derived from some hay in the stomach of a horse that had been killed by arsenic, I counted twenty-eight distinct crystals of arsenic (arsenious acid), in a space the 1-200th of an inch square. The greater number of these crystals had a diameter of the 1-2000th of an inch; some were distinctly recognised which had a diameter less than the 1-4000th of an inch. In general the octahedra are not perfect, but truncated at the solid angles.

Precipitation as sulphuret.—Another process for procuring evidence of the presence of this poison in organic liquids, consists in precipitating the arsenious acid in a state of sulphuret, and in decomposing this compound by an alkaline flux to obtain metallic arsenic, or by nitro-muriatic acid, to obtain arsenic acid. Sulphuretted hydrogen gas should be passed into the suspected liquid, previously filtered and acidulated with muriatic acid. When
all further precipitation has ceased, the liquid should be filtered, the precipitate collected, dissolved in ammonia, and reprecipitated by an acid. By digesting it in water, alcohol, and diluted muriatic acid successively, it may be deprived of any organic matter combined with it, sufficiently to allow of its reduction by soda-flux or metallic silver in the manner described (p. 75.) The sulphuret has sometimes a dark brown colour from adhering organic matter; it is then better to transform it to arsenic acid by boiling it in nitro-muriatic acid, and afterwards slowly evaporate the acid liquid to dryness. During this process the organic matter is entirely destroyed, and a dry residue of arsenic acid is obtained and rendered fit for testing, by dissolving it in distilled water; or the sulphuret may be deflagrated with nitre, and arseniate of potash then procured. In this case the surplus nitric acid should be driven off by pure sulphuric acid. An abundant deposit of metallic arsenic may be obtained in either case by boiling the liquid with muriatic acid and copper-gauze. In this way it is easy to analyse wine, coffee, tea, milk, porter, brandy, and similar liquids, for arsenic. The yellow precipitate must be submitted to some of these corroborative tests. I have known an instance in which a large quantity of orange peel had been eaten and had caused death, and the contents of the stomach acquired a yellow colour from sulphuretted hydrogen gas, like that produced by arsenic. There was no deposit, and the yellow colour did not disappear on adding ammonia.

The contents of the stomach are often mixed with lumps of arsenic, which may be separated by throwing those portions that do not pass through a filter into a large glass of distilled water, and after giving to it a circular motion, suddenly pouring off the supernatant liquid, when the heavy portions containing arsenic will be found at the bottom. The lumps left in the contents may be easily removed, dried on filtering paper, and tested. If the arsenic has been taken in fine powder, there will be no lumps, but it will probably be deposited in masses, mixed with mucus and blood, on the coats of the organ, chiefly in those parts where it is much inflamed and ulcerated. The arsenic in this state looks like moistened plaster of Paris, but it is of a darker colour, and when examined by a lens it is crystalline. It may be removed on a spatula, spread in masses on filtering paper, and slowly dried. As it dries the granules will detach themselves from the mass, and they may then be easily tested either by the Reduction or by Reinsch's process; i.e. by boiling the suspected particles, or even the stained portions of paper on which the organic matter has become dried, with muriatic acid and copper-gauze. Mucus, blood, or even a layer of the mucous membrane of the stomach, may be thus readily tested. This is in general the only method which it is now necessary to employ. By the
use of numerous tests and processes, a witness only exposes his evidence most unnecessarily to many ingenious objections. It is sufficient, after having obtained a metallic deposit on copper, to procure from it crystals of arsenious acid, to examine them by the microscope, and to demonstrate that they are really arsenic, by dissolving them in water, and applying the liquid tests. When the sublimate is in a quantity too small for the application of the liquid tests, it may be dissolved in nitric acid, evaporated to dryness, and either the nitrate or the ammonio-nitrate of silver may be applied to the dry residue. It is necessary to remark in reference to the application of the last-mentioned process, that there should be no free acid present, because the arseniate of silver is very soluble in acids. The ammonio-nitrate of silver may be sometimes, therefore, advantageously substituted for the simple nitrate.

In forming a judgment of the quantity of arsenic procured by Reinsch's process, it may be stated that only three-fifths of the arsenious acid employed are obtained in crystals by heating the copper. Dr. Geoghegan, of Dublin, has published some very interesting observations on this subject, for an account of which I must refer the reader to his paper in the Dublin Quarterly Journal for February, 1851. He has found that while the whole of the arsenic is deposited, but little more than one half can be re-obtained by sublimation in the crystalline state.

Dr. Rainey states that 1-1000th of a grain of arsenious acid will give a full steel colour to one square inch of copper surface, and he properly advises the analyst not to waste the arsenic (when present in small quantity), by spreading it in a thin film over too large a surface of copper. (See Proceedings of Glasgow Phil. Soc., December, 1849.) Dr. Macalagan has made some practical remarks on this subject, for which I must refer the reader to the Edinburgh Journal of Medical Science for 1848-9.

A plan which will be found convenient for preliminary testing, is to introduce the end of a fine and highly polished copper wire, with a small piece of copper-gauze attached to it, into the boiling acid liquid: it may be used for the purpose of stirring instead of a glass rod, and occasionally removed for examination. So soon as a closely adhering violet or steel-coloured deposit appears on the copper, the wire should be removed, and other portions of copper-gauze (containing 16,000 apertures to the square inch, and presenting a comparatively large surface for deposit) may be successively introduced until they cease to be coated. From one or more of these pieces, crystals may be obtained, and their nature proved by the processes above described.

When arsenic is discovered in the stomach mixed with food, it does not necessarily follow that it has been administered in that particular article of food. Should the person have partaken of food such as milk or gruel, subsequently to the swallowing of
arsenic, these fluids will necessarily acquire an arsenical impregnation from the poison already contained in the stomach. The patients may have taken the arsenic in one kind of food, when another and an innocent description of food might thus inadvertently be pronounced to have been the vehicle. (See on this point the case of Ann Merritt, London Med. Gaz., Aug. 16, 1850, vol. xlv. p. 291.

It is unnecessary in this place to enter into a comparison of the two processes above noticed, in respect to their relative powers of enabling the analyst to detect minute quantities of arsenic. It may be conceded that Marsh’s process will detect a smaller quantity of arsenic than the process of Reinsch, but the latter, when the quantity of liquid is small, will detect the 1-150th or the 1-200th part of a grain of the poison, and this is itself a point of delicacy in analysis, which, when the issues of life and death are involved, might almost suffice to justify a reasonable distrust of the resources of science. It would require considerable courage to go beyond this, and it appears to me that in a criminal case it would not be safe to depose to the presence of arsenic from Marsh’s process alone, when the quantity of poison was too small to admit of separation or corroboration by the process of Reinsch. When the point of detection by Reinsch’s process has been passed, then we increase the chance of fallacy to which Marsh’s process is always exposed, by the fact that such very minute traces of arsenic may have existed in some portion of the zinc or sulphuric acid, or even in the apparatus employed. It was this over-reliance on the extreme delicacy of the process in researches where it admitted of no corroboration whatever, that led to the great error committed by Orfila, of asserting that arsenic was a natural constituent of the human body!

Detection of absorbed arsenic in the tissues.—When arsenic cannot be detected in the contents of the viscera, it is necessary to adopt some method of extracting from the blood, secretions, muscles, or viscera of the deceased, that portion of the poison which has been absorbed. In most cases of acute poisoning arsenic will be found, but in variable quantities, in every one of the soft structures of the body—more abundantly in the viscera of the abdomen than elsewhere. The processes commonly employed for the discovery of arsenic in the tissues are those of MM. Danger and Flandin, and of Reinsch.

1. MM. Danger and Flandin carbonise the animal matter by boiling it to dryness in a small quantity of strong sulphuric acid, equal to about one-third the weight of the dried organic matter. They digest the resulting carbonaceous ash in nitro-muriatic acid, and after driving off the acid by a moderate heat, treat the residue with distilled water. This process, if arsenic be present in the viscera, yields arsenic acid,—a compound, the nature of which may be easily demonstrated (page 75). In pursuing this process
I obtained from seven ounces of the liver of a man poisoned by arsenic, about a dozen minute sublimates, as well as the action of the vapour of the flame on ammonio-nitrate of silver. M. Blondlot has advised that the carbonisation should not be carried to dryness, as it occasions a loss of arsenic; but when the liquid is of a pasty consistency, he passes into it a current of chlorine; the liquid is then filtered, and introduced into Marsh's apparatus, where it produces but little froth. (Comptes Rendus, 1845, ii. 32.) There can be no doubt that by the use of nitroleumuratic instead of nitric acid, a portion of the arsenic is volatilised and lost as chloride.

2. The process of Reinsch is, however, more easily applied than that of M. Flandin: it is simply this. The soft organs (and for this purpose the liver is preferable) are to be cut into very small pieces and boiled in a mixture of one part of pure muriatic acid and from six to eight parts of water, for two hours, or until the whole of the organic matter becomes a soft magma. The liquid may then be strained, and the residue pressed. If the quantity be large, it may be concentrated by evaporation. The copper-gauze, foil, or fine wire should be next introduced, the acid liquid boiled, and half an hour or an hour allowed for the deposit, if necessary. Should a deposit be formed on the copper, its nature must be positively determined in the way already described (p. 79). I have had occasion to apply this process to the detection of absorbed arsenic in the tissues in numerous cases of arsenical poisoning, with the most satisfactory results. A witness, in making use of it, must always be prepared to meet the following objection—namely, whether a deposit resembling that of arsenic may not be formed on the surface of copper by long boiling with animal matter (free from poison) and muriatic acid. Having tried on many occasions the liquid contents of the human stomach, the viscera, and even common muscle (beef), as well as various articles of food, in order to determine this point,—the result has been, that except when arsenic was added, or when there was a very strong suspicion of its presence, no metallic deposit was formed on the copper. The metal came out of the vessel un tarnished, or there was only a slight superficial discoloration (from oxide or subchloride) easily removed by friction. It would be wrong, however, to assert, whatever suspicions may exist, that arsenic was present in any case, unless crystals of arsenious acid are obtained from the metallic deposit on copper. The analyst should remember that the liver, spleen, and kidneys are the organs best fitted for yielding arsenic under these circumstances. I have found arsenic by Reinsch’s process, in the liver, after sixteen months’ and two years’ interment. (Case of Reg. v. Southgate, Chelmsford Lent Assizes, 1849, and Reg. v. Bacon, Lincoln Summer Assizes, 1857.)

As mercurial or antimonial medicine, or both, may have been
given to a person suffering from the effects of arsenic, the analyst must be prepared to find occasionally mixed deposits on the copper. Mercury sublimes with the arsenic, and may be detected by the microscope in the midst of, and adhering to, the crystals of arsenious acid. Antimony may be found by a special process, to be described hereafter. In the case of _Reg. v. Bacon_ (supra) arsenic, mercury, and antimony, were found.

M. Schneider, and Dr. Clark, of Aberdeen, have suggested that the arsenic contained in organic liquids or solids may be procured as chloride in a receiver by distilling the organic matter with a mixture of common salt and sulphuric acid. The chloride of arsenic thus obtained in a pure state may be subsequently analysed by any of the usual processes. (Pharm. Journ., July, 1853, p. 38.) In reference to the detection of absorbed arsenic, —as this substance is much used in skin and other diseases, its discovery does not necessarily establish the cause of death, or an act of criminal administration.

If the patient has died with arsenic in the body, there is scarcely any limit to the period at which it may be detected. In the cases of two children examined by Mr. Herapath, in July, 1849, the poison was discovered in the remains of the dead bodies after eight years' interment; in another case by Dr. Glover after twelve years (Lancet, July 9, 1853, p. 41); and in a remarkable instance which occurred to Dr. Webster, of Boston, it was discovered in the remains of a body, after fourteen years' burial in a tomb. It has been sought for, and not found, at much shorter periods after death when there was a very strong suspicion that the poison had been taken: but it is highly probable that in these cases there was little or no arsenic in the bodies at the time of interment. The longer a person has survived after taking the poison, the less probable is it, _ceteris paribus_, that arsenic will be found in the remains.

In those cases in which arsenic is found in a solid state after long interment, it is generally under the form of sulphuret or yellow arsenic, the white arsenic being thus changed in composition and colour during the process of putrefaction. This change of colour, however, is not always met with, even in bodies which have been buried for a year, or longer. (See Guy's Hosp. Reports, Oct. 1850, p. 206.) Care must be taken not to confound stains produced by bile on the stomach or intestines after long periods of interment, with those caused by sulphuret of arsenic.

The medical practitioner should be aware that a crystalline substance resembling arsenic is very often produced in the dead stomach at variable periods after interment. These crystals consist of ammonio-phosphate of magnesia derived from putrefaction. I have met with them in several instances within the last few years. They have been mistaken for arsenic, and their occur-
rence has in some instances led to unjust suspicions and accusations. (See Guy’s Hosp. Reports, Oct. 1850, p. 222.) An analysis will of course remove any doubt. For many important facts connected with the quantity of absorbed arsenic deposited in the tissues, the time at which it is deposited, as well as the relative portions found in different organs, and in the same organ at different periods after the taking of the poison, I must refer the reader to the paper of Dr. Geoghegan. (Dublin Quarterly Journal, Feb. 1851.) According to observations made by this gentleman, the largest quantity of arsenic was found in the liver, in about fifteen hours after the poison had been taken. It amounted to two grains for the whole organ. The earliest period at which he met with it was seven hours,—the quantity being 0.8 grains, and the latest fourteen days, the quantity in the whole organ being 0.17 grains.

It is important, in reference to the tissues, to observe that arsenic may be found in them even at an early period, when it is either absent or only doubtfully present in other parts. In a case referred to me by Mr. Gell, coroner for Sussex, in May, 1854, the deceased, Burton, died within four hours after he had been attacked with symptoms of poisoning by arsenic. Arsenic was found in small quantity in the stomach, duodenum, and rectum. It was also detected in the liver and spleen; and the proportion found was greater in the latter than in the former organ. The precise time at which the poison was taken could not be determined; but the fact mentioned shows that its deposition in the tissues takes place very rapidly. In the cases of the Allee family, referred to me by Mr. Carter, coroner for Surrey, in January, 1854, the body of the mother was exhumed after a month. Arsenic was not found in the stomach or bowels, but it was readily detected in a small portion of the liver. The poison had probably been taken several days before death. This fact is of considerable importance in relation to a medical opinion of the presence or absence of poison in a dead body. It is very commonly the practice to confine an analysis to the stomach and bowels only; and when no poison is found therein, to report that no poison exists in the body, and to refer death to natural causes. It is clear, however, from the above case, that such an opinion might be erroneous unless the liver or spleen had undergone a chemical examination. In reserving viscera for analysis, a portion of the liver should therefore always be examined. In these cases arsenic was detected by Reinsch’s process; but the copper-gauze used was not distinctly or sufficiently coated with metallic arsenic until it had been boiled with the viscera for three-quarters of an hour.

If the person has lived fifteen or sixteen days after having taken the poison, no trace may be found in the tissues or in any part of the body. Orfila had expressed this opinion from his experiments on animals; its correctness has been strikingly con-
firmed by the case of Dr. Alexander, who died in sixteen days from a dose of arsenic taken by mistake in arrow-root. Dr. Geoghagan, who was deputed to make an analysis of the stomach and other viscera, found no trace of the poison, either absorbed or unabsorbed, in any part of the body which he examined. (See Med. Times and Gazette, April 18, 1857, p. 389.)

On the quantity of arsenic found by chemical analysis. — It need hardly be observed, that the quantity found in the stomach or viscera can convey no accurate idea of the quantity actually taken; since more or less of the poison may have been removed by violent vomiting and purging as well as by absorption. A large quantity found in the stomach or bowels indicates a large dose; but the finding of a small quantity does not prove that the dose was small. It is singular that, notwithstanding these very obvious causes for the removal of a poison from the stomach, barristers should so frequently address the inquiry to a medical witness — whether the quantity of poison found in the viscera was sufficient to cause death? Whether this question be answered in the affirmative or negative, is a matter which cannot at all affect the case, since either no traces of poison, or but a very small portion, may be found in the viscera, and yet the deceased may have assuredly died from its effects. (See the case of Dr. Alexander, supra.) Absorbed arsenic, as it exists in the tissues, is never found except in very minute proportion. (See ante, p. 88.) Thus then, whether much or little be detected, is, medically speaking, unimportant; since the fact of death having been caused by poison does not, in the least degree, rest upon the precise quantity which happens to remain in the body at the time of death. It has been truly remarked by Orfila, in regard to arsenic, and it equally applies to all poisons, that that portion which is found in the stomach is not that which has caused death; but the surplus of the quantity which has produced fatal effects by its absorption into the system. The inquiry should therefore be directed to the probable quantity of poison taken; not to how much remains in the body at the time of death. There is scarcely a trial for criminal poisoning, however, in which this question is not put to a medical witness, either by the judge or the counsel for the prosecution or defence. Supposing poison to be found in the stomach, but not in sufficient quantity to destroy the life of another person — is it therefore to be assumed that the person did not die from its effects? This would be equal to laying down the rule, in face of the most indisputable evidence to the contrary, — that poisons, when taken into the body, are permanently fixed there, and are never liable to be removed by vomiting, purging, absorption, and elimination! The real object of the toxicologist is to discover the poison by clear and undoubted evidence. If more than sufficient to cause death be discovered, then the dose must have been larger than was neces-
sary; but if this proof be always required, how are those cases of criminal poisoning to be dealt with in which a crafty professional poisoner like William Palmer administers a dose only just sufficient to destroy life, or in which the deceased, by the strength of his constitution (case of Dr. Alexander, p. 89), happens to survive the effects for some days or weeks, and ultimately dies of exhaustion? No fatal dose of poison could be detected under these circumstances. Orfila has satisfactorily demonstrated the fallacy of this objection to medical evidence, and the danger of a Court of law relying upon it. (See Ann. d’Hyg. 1845, i. 347; also Toxicologie, ii. 731.)

It has been supposed that the quantity of arsenic found in the stomach and bowels might throw a light on the question, whether the poison had been taken voluntarily with the intention of committing suicide, or whether it had been criminally administered by another. There is no doubt that a much larger dose may be taken by a suicide than could be secretly administered by a murderer; and thus, if a large quantity be found in the stomach, it is supposed to furnish a presumption in favour of suicide and against murder. Suicides have been known to take as much as two tablespoonfuls, or one thousand grains, of arsenic. How much may remain in a dead body must, however, depend on the amount of vomiting and purging, and the length of time the person survives. In one case of murder by poison, I found in the stomach, on the exhumation of a body, eighteen months after death, twenty grains of arsenic. In the case of L’Angelier (Reg. v. Madeline Smith, Ed. High Court of Justiciary, June and July, 1857), Dr. Penny stated in evidence that the quantity of arsenic which he found in the stomach and contents of deceased amounted to eighty-eight grains, and that some parts of this was in hard, gritty, colourless, crystalline particles. As there was arsenic in the contents of the intestines, and there had been vomiting and purging, it is obvious that the deceased must have taken a very large dose of the poison; and it was one of the difficulties of the case to determine how the deceased could have taken the poison in so large a quantity unknowingly. The quantity found amounted to no more than half a teaspoonful; and admitting that one half of the dose taken had been ejected, the question resolves itself into this: whether a teaspoonful of arsenic might not have been homicidally administered in chocolate, gruel, or some viscid liquid, or in a state of admixture with solid food. Although it is unusual to find half a teaspoonful of arsenic remaining in the stomach in a case of homicidal administration, it appears to me impossible to admit that this fact is inconsistent with an act of murder. A man half intoxicated might be thus poisoned; and if death took place in a few hours, even a larger quantity than that which was here found might remain in the stomach.

The condition of the arsenic found in a dead stomach should be
specially noticed. A witness should be prepared to say, whether it is in fine powder or coarse fragments; whether it is mixed with soot or indigo, or whether it is in the ordinary state of white arsenic. These points may be material as evidence.

Arsenic in the soil of cemeteries. — It appears from the researches of several toxicologists, that the soil of certain graveyards contains a compound of arsenic, in an insoluble form. In eight trials on different soils, Orfila found three of them arsenical. He used about six pounds of earth in the experiment. As there was no sign of arsenic, except when an acid was used, he inferred that it existed in the state of an insoluble arsenite or arsenate. The researches of Flandin have corroborated this result; and, in one instance, this experimentalist estimated that the quantity of arsenic, in an insoluble form, in about a pound of earth, did not exceed the twentieth part of a grain! Admitting the existence of arsenic as a natural constituent of certain soils, it is necessary to determine how far its presence may affect the chemical evidence of the existence of this poison in the remains of bodies which have undergone exhumation. If the coffin be cracked or entirely destroyed, so that the earth has become intermixed with the remains, and that which surrounds the coffin yields traces of arsenic, it is evident that no reliance could be placed upon the inference that the arsenic existed in the human body, unless the poison found in the remains was in a soluble form and in extremely large proportion. The reader will find cases in which doubts based upon the origin of the arsenic detected in the decomposed dead body led to the abandonment of chemical evidence. (Flandin, Traité des Poisons, 674, 683.) A difficulty of this kind cannot, however, when proper precautions are taken, often present itself in practice. A body buried in a coffin is rarely so far decomposed as to become covered by the soil from the disintegration of a coffin in a period shorter than from seven to ten years; and until such a complete disintegration has taken place, it is not easy to perceive how the presence of an insoluble arsenical compound, as a natural constituent of the soil, can present any objection to the results of an analysis. In the examination of these soils, it has been ascertained that no arsenical compound soluble in water has existed in them; therefore, if distilled water should yield, on boiling the remains, a solution of arsenic, the presumption is that it could not have been derived from the soil. It has been supposed that the arsenic may have been carried by percolation from the soil into the body; but in this case, as Flandin has observed, the exterior of the body would contain more than the interior: while in a case of arsenical poisoning (except when dependent on local application) the liver and stomach would yield more than the skin. (See Galter, l. 368; Flandin, l. 429, 741.) A case, in which this question arose in reference to a dead body which had been interred for a period of three years, has been published
by M. Barse. (See Edinburgh Monthly Journal, Nov. 1851, p. 483.)

Arsenic in solids.—Arsenic may exist in solid articles of food, such as bread, pills, and powders;—in ointments, and certain candles;—or matters vomited by a person poisoned may sometimes be imbibed by articles of clothing or furniture. In all these cases we should simply boil the solid matter with the addition of muriatic acid and copper; or if we wish to separate the whole of the poison, we may proceed, as in the case of organic liquids, by using a current of sulphured hydrogen gas. A cat was poisoned by half a drachm of arsenic—the animal died in about nine hours. No trace of poison was found in the body; but a small part of the floor of the room, where the cat had vomited, was scraped off, boiled in water, and yielded on analysis clear evidence of the presence of arsenic.

Arsenite of Potash. (Fowler's Solution.)

All the compounds formed by arsenious acid with the alkalies are poisonous. Those of potash, soda, and ammonia, are soluble in water, and, therefore, act with more energy. The Arsenite of Potash is the only preparation which here requires notice. It is used in medicine, and is well known under the name of Fowler's Mineral Solution, or Tasteless Aqueous Drops. It is made by boiling arsenious acid with carbonate of potash, the latter being in slight excess, and it is coloured with compound tincture of lavender. In the preparation of the London Pharmacopoeia, there are four grains of arsenious acid in a fluid-ounce (or eight fluid-drachms) of the solution. Its real strength may be affected by any impurities in the arsenious acid employed. The preparation used in Scotland is of the same strength; but that of the Dublin College is rather stronger. The action of this liquid as a poison, in large doses, is in all respects analogous to that of arsenious acid.

There is one form of poisoning by this compound which it is desirable to point out. A mixture of arsenic, soft soap, and tar-water, is largely used in agricultural districts for killing the fly in sheep. In June, 1853, a woman swallowed a quantity of this liquid. She soon afterwards experienced severe pain in the stomach, nausea, and violent vomiting, followed by purging, great heat in the throat and stomach, with intense thirst. She died in twenty-four hours after taking the poison. The mucous membrane of the stomach presented a few patches of inflammation, but was of a pale bluish colour in other parts. The lining membrane of the gullet at the part where it entered the stomach was of a bright pink colour. The duodenum and upper part of the small intestines were highly inflamed. A portion of the liquid which deceased had taken was found to be highly alkaline, and smelt strongly of tar. It was a saturated solution
of arsenite of potash, with excess of carbonate. When paper saturated with the liquid was burnt, a white smoke was evolved, which, when received on a cool surface of glass, gave the usual indication of arsenious acid with ammonio-nitrate of silver. The symptoms and appearances were similar to those observed in poisoning by arsenious acid.

Dr. Michell lately met with a case in which a mixture of arsenic and soft soap, applied locally, produced all the well-marked effects of poisoning by arsenic, as well as an intense local action. A man applied this mixture to his scrotum and armpits for the purpose of killing pediculi. In twelve hours he began to feel a stiffness in the neck, and a slight difficulty in swallowing. The cuticle of the scrotum peeled off, leaving the cutis inflamed and bleeding. There was great thirst, with headache and a sensation as if the hair was being pulled up by the roots. There was irritability of the stomach, with vomiting, purging, and pain on pressure. He said that he felt as if his bowels were on fire. Under treatment this man recovered. (Med. Times and Gaz. Dec. 10, 1853.)

According to Mr. Bullock, the pharmacopeial preparation is not a true arsenite of potash, but a solution of arsenious acid in carbonate of potash, with a minute trace of the arsenite. (Lancet, Dec. 21, p. 674.) The uncertainty of its composition may possibly account for the variable effects produced by this liquid. In a former page I have related the case of a female who was killed by half an ounce, in divided doses, in five days (see ante, page 72); while Mr. Hunt, who has largely employed arsenic in the treatment of skin diseases, states that where the susceptibility is not great, a dose of two drachms of the solution (= one grain of arsenic) can be borne about as well in one dose as in twenty. He quotes a case in which a patient took two drachms of this solution, in twenty-four hours, by mistake. It cured the ague for which it was prescribed, and had no injurious effect. (Med. Times, September 14, 1850, page 270.) It is difficult to explain such anomalies by varying susceptibility only; they are more probably due to the uncertainty of composition in the preparation employed.

The ordinary chemical processes for arsenic are sufficient for its detection in this solution.

Solution of Chloride of Arsenic.  
(Liquor Arsenici Chloridi.)

This is a pharmacopeial solution of arsenic in diluted hydrochloric acid. It contains one grain and a half of arsenious acid in one fluid ounce, which is equal to the small proportion of three-sixteenth of a grain to a fluid drachm. Mr. Phillips states that it is a highly poisonous preparation, and from a case which I saw in Guy's Hospital in May, 1857, this statement is confirmed. An adult female took, in three doses, thirty minims over a period
of twenty-four hours. The quantity of arsenic thus taken was not more than the tenth part of a grain, and yet the symptoms which followed were of a severe kind,—resembling those of chronic poisoning. There was constriction of the throat,—pain and irritation of the stomach and bowels,—tingling and numbness of the hands and feet,—loss of muscular power, and a feeling of extreme depression. The medicine was withdrawn, and the patient slowly recovered. It seems that she had not taken arsenic previously, and there was no evidence of the existence of a peculiar susceptibility to the effects of the poison. The quantity taken was very small to produce such alarming effects. The usual medicinal dose of this solution is from three to ten minims. It has about three-eighths of the strength of the solution of arsenite of potash.

**Metallic Arsenic. Fly-Powder.**

It is generally considered that metallic arsenic is not poisonous; but, as this metal is very easily oxidised, it speedily acquires poisonous properties. According to Berzelius, the metal is slowly converted by exposure to the air, to a pulverulent suboxide of a black or brownish-black colour. This is commonly called Fly-Powder, a name also applied to the arsenical cobalt ores reduced to powder. Thus, what is called the Tunberg ore, a mixture of cobalt, arsenic, iron, and sulphur, is largely used on the continent under the name of Fly-Powder: and, as it comes within the reach of children, it frequently gives rise to accidents. A few years ago, Dr. Schobens was called to a man who had taken some by mistake for a purgative. He was soon attacked with the usual symptoms of poisoning by arsenic. He swallowed a large quantity of milk, which occasioned immediate vomiting. As fifteen hours had elapsed before a medical man saw him, no treatment was of any avail, and he died from the effects of the poison. In another case, a child, aged four years, swallowed a portion of fly-powder. The hydrated sesquioxide of iron was given every half hour, and the child recovered the next day. (Monthly Jour. Med. Science, Sept. 1846, p. 228.) The exact quantity taken in this case is not known; but there is no doubt that the poison is but little inferior to arsenious acid in activity; and the symptoms and appearances after death from a fatal dose would be similar. This substance is not much known in England. A woman was convicted in France for poisoning her husband with it in 1844. (Briand, Man. Comp. de Méd. Lég. 452.) It owes its poisonous properties to arsenious acid, of which, with the metal, it appears to be a mechanical mixture.

**Fly-Water** is a name applied to solutions of various arsenical compounds in water. Mixtures of this kind are formed by dissolving one part of the arsenite of soda or potash and two parts of sugar in twenty parts of water. Paper soaked in this solution,
and dried, is used for poisoning flies; and perhaps, this is the safest form in which arsenic can be used for such a purpose.

A case of poisoning by fly-water, in which two grains and a half of arsenious acid destroyed the life of an adult in thirty-six hours, will be found reported in the Medical Gazette (vol. xxxix. page 116.)

**Arsenic Acid.**

This is an artificial product almost entirely confined to the chemical laboratory. Orfila states that it is a more powerful poison than arsenious acid, but he does not adduce any cases in support of this opinion. I have not been able to find any case of poisoning by it in the human subject. Dr. Glover ascertained that four grains of the acid, dissolved in two drachms of water and introduced into the stomach of a stout rabbit, killed the animal in four hours, with the symptoms of irritant poisoning, and an affection of the nervous system. (Ed. Med. and Surg. Jour., vol. lviii. page 121.)

**Analysis.** — Arsenic acid is a white uncrystalline deliquescent solid. 1. It is not entirely volatilised on platinum foil by the flame of a lamp. 2. It is very soluble in water, forming a highly acid solution. 3. It is precipitated of a brick-red colour by nitrate or the ammonio-nitrate of silver. In these characters it differs from arsenious acid. 4. It yields readily an arsenical sublimate with charcoal. 5. It yields deposits with copper and muriatic acid, or in Marsh's apparatus. But Dr. Rainey has shown that Reinsch's process does not act so delicately with the arsenic as with arsenious acid. The arsenic may, however, be converted to arsenious acid by a current of sulphurous acid gas. Arsenic acid is also precipitated, although slowly and of a pale yellow colour, by sulphuretted hydrogen gas. In these properties it resembles arsenious acid.

**Arseniate of Potash.**

The arseniates of potash and soda must be regarded as active poisons, although there are but few instances on record in which life has been destroyed by them. Dr. Christison states that, in the course of his reading, he has met with only two reported cases of poisoning by arseniate of potash (Op. cit. 284). The tests are the same as for arsenic acid. A coarse sort of blotting-paper, soaked in a solution of arseniate of potash, is now extensively sold under the name of "Papier Moure." It is erroneously represented that the substance with which it is impregnated is not poisonous to human beings.

**Sulphurets of Arsenic.**

There are several kinds met with in commerce — Orpiment or Yellow Arsenic, and Realgar or Red Arsenic. They are poisonous in consequence of their containing a large proportion
of free arsenious acid; this sometimes amounts to as much as from 30 to 70 per cent. of their weight. They are sometimes used as poisons: in several criminal trials in England it has been proved that orpiment was the substance used.

Symptoms and appearances.—The sulphurets of arsenic produce symptoms and appearances after death similar to those caused by arsenious acid; but the dose required to destroy life must vary according to the proportion of arsenious acid with which the sulphuret happens to be mixed. This is not a common form of criminal poisoning: the intense colour of the poison would lead to suspicion. It was with orpiment that Mrs. Smith was poisoned at Bristol in 1835. (Med. Quart. Rev., July, 1835, p. 390.) Its colour might cause it to be mistaken for mustard. Orpiment has been known to cause death by external application as a depilatory (see Annales d’Hygièue, 1834, i. 459); a result which might be expected from the quantity of arsenious acid with which it is mixed. There is a form of depilatory used, which consists of one part of orpiment, twelve parts of quicklime, and ten parts of starch, made into a soft paste with water (Pereira, i. 162), the use of which must be always attended with danger.

Analysis.—The powdered sulphurets yield a solution of arsenious acid on boiling them in water acidulated with muriatic acid. They readily give the well-known sublimate of metallic arsenic, with soda-flux, silver, and the hydrogen apparatus. They also yield a deposit of arsenic when boiled with copper and muriatic acid. Orpiment is insoluble in muriatic acid, but it is readily dissolved by caustic potash. Organic mixtures.—The sulphuret being insoluble in water, it is in general easily separated mechanically by allowing the matters mixed with it to become dry upon bibulous paper. If the sulphuret cannot be separated mechanically, the organic matter suspected to contain it should be dried and boiled with nitric acid to dryness. The arsenic of the sulphuret will be found, as arsenic acid, soluble in water. Another impure sulphuret, sold as King’s yellow, is composed, according to Dr. Christison, of sulphuret of arsenic, lime, and sulphur. It is highly poisonous, and is extensively sold as a pigment. A case of alleged poisoning by this substance is reported in the Edinburgh Monthly Journal (Sept. 1846). The sulphuret of arsenic is easily separated from the mixture by digestion in solution of ammonia.

Arsenuretted Hydrogen.

Symptoms and effects.—This is a gaseous poison of arsenic, producing, when respired in small quantity, very serious effects upon the system. It has already occasioned death in at least three instances. The gas is an artificial product, and is formed in a chemical laboratory in various ways,—one method has been already described in speaking of Marsh’s process; and its highly
POISONING BY ARSENICATED HYDROGEN. 97

poisonous properties render it necessary that caution should be used in the employment of this mode of testing. The gas is most effectually decomposed, and prevented from diffusing itself, by passing it into a solution of nitrate of silver. This form of gaseous arsenical poisoning has been hitherto purely accidental. Gehlen, a German chemist, was killed by accidentally breathing a small quantity. He suspected that the gas was escaping from some part of the apparatus which he was using, and applied his nose for the purpose of detecting it; although he respired but a very small quantity, he was seized in about half an hour with vomiting, shivering, and great prostration of strength. He died on the ninth day. The most complete history of this kind of poisoning has been published by Dr. O'Reilly, of Dublin. He has been kind enough to forward me the particulars of the subjuncted case.

A gentleman, for the sake of experiment, wished to respire about one hundred and fifty cubic inches of hydrogen gas. It unfortunately happened that the sulphuric acid, which he used for making the hydrogen, was largely contaminated with arsenic; and immediately after respiring the gas, he was seized with giddiness and fainting, constant vomiting of a greenish-coloured matter, and dull pain in the epigastrium. There was also complete suppression of urine. He died in about six days. On dissection, the liver and kidneys were found of a deep indigo blue colour,—the mucous membrane of the stomach was easily separated; and there were two distinct patches of inflammation in the greater curvature. There was a quantity of reddish-coloured fluid effused in the chest, and in about ten ounces of this fluid, Dr. O'Reilly detected arsenic by Marsh's process. From experiments made on the sulphuric acid, it is supposed that the deceased must have inhaled a quantity of arsenic equivalent to about twelve grains of arsenious acid.

I am indebted to Dr. Monatt, of Calcutta, for the particulars of another case, that of Prof. Robertson, of Calcutta Medical College, who, while delivering a lecture on arsenic, accidentally breathed a portion of this gas which was escaping from a Marsh's apparatus. The first symptoms were a sense of burning and of constriction in the throat, followed by irritability of the stomach, vomiting of liquid, at first bilious, and afterwards coffee-coloured, with a burning pain through the whole alimentary canal. Four pints of bloody urine were passed, and this on examination was found to contain arsenic. There was constipation of the bowels, fever, full, hard, frequent pulse, dry, hot, unperspiring skin, restlessness, anxiety, and great prostration of strength. He did not recover from these symptoms until the twenty-second day.

Analysis.—The chemical properties of this gas have been already described. (See Marsh's Process, ante, p. 78.)
CHAPTER X.

CORROSIONSUBLIMATE—TASTE AND SOLUBILITY—SYMPTOMS—ITS EFFECTS COMPARED WITH THOSE OF ARSENIC—SLOW OR CHRONIC POISONING—SALIVATION FROM SMALL DOSES OF MERCURIAL MEDICINES—FROM OTHER CAUSES—APPEARANCES AFTER DEATH—QUANTITY REQUIRED TO DESTROY LIFE—PERIOD AT WHICH DEATH TAKES PLACE—FATAL DOSE—TREATMENT—CHEMICAL ANALYSIS IN POWDER AND SOLUTION—PROCESS IN ORGANIC LIQUIDS—CALOMEL—WHITE AND RED PRECIPITATES—SULPHURES OF MERCURY.

Corrosive Sublimate.

This substance is usually known under the chemical name of Perchloride of Mercury; but, according to some distinguished authorities, it is a Chloride. To prevent any confusion from scientific chemical nomenclature, the old and popular name of Corrosive Sublimate is here used. It is not often taken as a poison. In the Coroner’s report for 1837–8, there were about fifteen cases of mercurial poisoning, in twelve of which corrosive sublimate was the poison taken. It is commonly seen under the form of heavy crystalline masses, or a white powder.

Taste and solubility.—The taste of corrosive sublimate is powerfully austere and metallic, so that no poisonous quantity of it could be easily swallowed, without the individual becoming immediately aware of it. It is very soluble in water, hot or cold, and speedily sinks in it, in which properties it differs strikingly from arsenic. I have found by experiment that one hundred grains of a cold saturated solution hold dissolved, at a maximum, ten grains of corrosive sublimate; and it is stated by most chemists that two parts of boiling water (212°) will dissolve one part of the poison. It is also readily dissolved by alcohol and ether; the last body takes up one-third of its weight, and has the property of abstracting it from its aqueous solution,—a principle which is sometimes resorted to for separating the poison when dissolved in organic liquids. It is soluble without change in nitric and muriatic acids, and it is a fact of some medical importance that common salt renders it more soluble in water.

Symptoms.—The symptoms produced by corrosive sublimate generally come on immediately or within a few minutes after the poison has been swallowed. In the first place, there is perceived a strong metallic taste in the mouth, often described as a coppery taste; and there is, during the act of swallowing, a sense of constriction almost amounting to suffocation, with burning heat in the throat, extending downwards to the stomach. In a few
Symptoms in the Acute and Chronic Pneumonia.

Violent pain is felt in the abdomen, especially in the region of the stomach, which is increased by pressure. Pain in the abdomen is, however, sometimes wholly absent. There is nausea, with frequent vomiting of large quantity masses of vomitus mixed with blood; and this is accompanied by profuse purging. The commencement is sometimes sudden and intense; in other cases it has been pain and vomiting. The pulse is weak, frequent, and irregular, and is scarcely perceptible when the symptoms become aggravated. The tongue is white and moistened—the skin is cold and clammy. The respiration difficult, and death is commonly preceded by之间的 restless, or general inanition. The external parts of the mouth when examined, are swollen, and sometimes present the appearance as if the cavity had been washed with a solution of nitric silver; the lips are often swollen. Suppuration of nose has also been frequently noticed among the symptoms. It is recorded in a well-marked case of pneumonia in the American Journal of Gynecology, in which a patient had some time passed away from the disease, and the patient was observed to have a nose which was discharging a quantity of pus from the nose. In another case, reported by Dr. White, in which a patient had been under treatment for a few months, and in which the symptoms were being more frequently mixed with blood. The symptoms produced by the convulsion in the first disease, the contents of the bowels were rare; but when they are in the course of recovery, they are more like those of dysentery, although sometimes and masses of hardened blood being very frequently observed.

Some chronic cases persisting.—The symptoms are much modified when the patient is taken to small doses of proper medicine for six days or weeks. There are sudden cases with marked symptoms, general aches and pains. The chronic cases become milder and peaceful; the tongue and pulse are
red and swollen, sometimes ulcerated, and there is fæcit of the breath. A deep blue line, like that observed in poisoning by lead, is sometimes found around the edges of the gums. The patient experiences difficulty of swallowing and breathing. The constitutional effects are indicated by looseness of the bowels, difficulty of breathing, spitting of blood, cough, general tremor of the limbs, and palsy, with slow fever and emaciation, under which the patient sinks.

Salivation — One of the most marked effects of slow or chronic poisoning by mercurial preparations is salivation or ptysialism, indicated by an increased flow of saliva. This is by no means a necessary symptom in cases of acute poisoning by corrosive sublimate, but it not unfrequently shows itself about the second or third day. In some instances the patient dies too rapidly for this effect to follow, but even when he survives some days, salivation is not always observed. In a case related by Dr. Venables, in which two drachms of the poison had been taken, and the woman survived for the long period of eight days, this symptom did not exist. In another case reported by Mr. Wood (Ed. Med. and Surg. Jour. li. 141), in which half a teaspoonful of the poison was taken, salivation was profuse in the course of a few hours. In a case which occurred at Guy's Hospital, in February, 1843, where two drachms had been taken, salivation commenced in four hours; but this is by no means the earliest period. Dr. Percy relates a case of poisoning by corrosive sublimate, in which the saliva was flowing profusely an hour and a half after the woman had taken a dose of thirty grains. (See Medical Gazette, 1843, i. 942.) In these early cases, it is alleged that fæcit of the breath is absent, but most practitioners will look chiefly to the production of salivation as a symptom. The local action of the poison is, in some of these cases, sufficient to account for the abundant flow of saliva, independently of the influence of the absorbed mercuric on the salivary organs. In Mr. Morris's case, in which half a drachm of the poison in powder was placed by the female on her tongue, the saliva flowed abundantly from the mouth, and the lips were much swollen. (Prov. Med. Jour., Nov. 18, 1843, p. 127.) This was undoubt-edly due to the local irritant action of the poison.

In the chronic form of poisoning, when the dose has been small and frequently repeated, we may generally expect to meet with salivation, accompanied by fæcit of the breath, and sponginess and ulceration of the gums. Should the person survive some time, this symptom is more commonly met with than not; but in looking for it as an indication of mercurial poisoning, a medical jurist must remember that some persons are wholly unsusceptible of this condition. On the other hand, there are cases in which the salivary glands are most easily excited, so that the usual innocent doses of mercurial medicines have been known to
produce salivation to such a degree as to cause death. Facts of this kind are of some importance, since charges of malapraphesis may be easily raised in respect to them. Dr. Christison mentions a case in which two grains of calomel destroyed life by the severe salivation induced, as well as by ulceration of the throat. Another was mentioned to me by a pupil, in 1859, in which five grains of calomel killed an adult by producing fatal salivation. From some cases related by Mr. Samuel, of Newark, it appears that two grains of calomel, divided into three powders, were given in the proportion of one powder daily (two-thirds of a grain) to a little boy aged eight. This small dose produced the most violent salivation, sloughing and exfoliation, from which he was some weeks in recovering. In another instance, a little girl, aged five, took daily for three days three grains of mercury and chalk powder. Her mouth was severely affected, sloughing ensued, and she died in eight days. In a third case a boy, aged eleven years, took three doses of this powder—one of six grains on the 14th, a similar dose on the 17th, and four grains on the 20th, making altogether sixteen grains. The most profuse salivation followed; sloughing commenced in both cheeks, and rapidly extended through them. The boy died in four days. Previously to the exhibition of the mercury he had recovered from an attack of fever. (Lancet, Dec. 20, 1851, p. 579.) In a fourth case, three grains of blue pill given twice a day for three days, making eighteen grains in the whole, were ordered for a girl aged nineteen, who complained of a slight pain in her abdomen. Severe salivation supervened, the teeth separated, and she died in twelve days. With respect to the effects of corrosive sublimate, Dr. Christison states that three grains of this substance in three doses caused violent salivation. (Op. cit. 408.) When this state results from the use of mild mercurial medicines in small doses, the severe effects may be in general referred to idiosyncrasy. A person may die under these circumstances, either from simple exhaustion or from extensive sloughing of the fauces, with exfoliation of the bones. When an individual has recovered from the first effects of acute poisoning by corrosive sublimate, he may die at almost any period from these secondary consequences. It is generally admitted by toxicologists, although the cases are rare, that salivation may be intermittent—i.e. that it may cease and reappear without more mercurial poison or any mercurial preparation being given in the interim.

**Profuse salivation from mercury dependent on morbid causes.**—In addition to the facts already detailed, respecting death from excessive salivation under the use of small doses of calomel, there are certain morbid conditions of the body which appear to have the effect of increasing the action of this medicine on the salivary glands. This kind of acquired idiosyncrasy exists especially in that form of disease called granular degeneration of the kidney.
which is characterised in its early stage by albuminuria. On this subject Dr. Craigie says, the great objection to the employment of any preparation of quicksilver for the cure of renal dropsy consists in the fact, that the use of the mineral is known to render the urine albuminous, to increase the inflammatory state of the system, and to induce the disease, the effects of which it is expected to remove. Another evil is, that in persons labouring under symptoms of granular kidney a very small quantity of mercury induces salivation, and renders the mouth tender and most painful. (Practice of Physic, ii. 1148.) This he considers to depend chiefly on the fact, that patients of this description have in general, if not always, been subjected previously to the full influence of the mineral in repeated courses. For these reasons, in his view, mercury should not be given without a previous trial of other remedies, as even assiduous watching will not always succeed in preventing bad effects. Dr. Christison informs me that he has repeatedly observed that mercurial action (salivation) is in these cases brought on by unusually small doses of the compounds of mercury, or unusually soon; and the action, under these circumstances, has been very violent, although not uncontrollable.

**Cancer oris. Canker of the mouth.**—Corrosive sublimate, as well as other mercurial preparations, is liable to produce gangrene of the mouth and fauces,—a state which may equally occur from spontaneous causes: death is commonly the result. In a case of this kind, supposing any mercurial preparation to have been given medicinally, it may become a serious question whether death actually resulted from the mercury acting as a poison, or from natural disease. Several fatal cases have occurred among infants and children; and the subject has become a matter of inquiry before coroners. Although salivation and its consequences are not common among children, as an effect of mercurial preparations, yet it is clear, from the cases already cited (p. 101), that small doses of mercury may have a most violent effect upon them, and render the suspicion of poisoning probable. Of two children, whose deaths became the subject of investigation under these circumstances, one was affected with hooping-cough, and the other with measles. Powders containing calomel were prescribed in both cases,—gangrene of the mouth supervened, and the children died. There was some reason to believe, from the evidence, that the mercury had really produced the effect attributed to it, at least in one of the cases. It is proper to remark, that this kind of disease,—gangrene of the mouth,—has been observed to occur in children to whom no calomel, nor any mercurial preparation whatever, had been given:—the subjects have been chiefly infants, badly fed and clothed, and generally labouring under, or recovering from, fever, small-pox, measles, or hooping-cough. It is, however, far more common as a con-
CORROSIVE SUBLIMATE. APPEARANCES AFTER DEATH. 163

sequence of measles than of other diseases, and it is always connected with a depressed state of the vital powers. Many cases of this kind are reported by Dr. Hennis Green (see Lancet, Dec. 1839). The disease is often vulgarly called "canker of the mouth." Dr. Dugas considers that children between five and eight years of age are specially liable to this form of mercurial salivation and sloughing. (Ed. Monthly Journal, May 1851, p. 461.)

Appearances after death. — These, as in the case of arsenic, are chiefly confined to the alimentary canal. Corrosive sublimate, however, affects both the mouth and fauces; the mucous membrane is softened, of a white or bluish grey colour, and sometimes inflamed; that lining the gullet is similarly affected, and partially corroded and softened. The mucous membrane of the stomach is more or less inflamed, sometimes in patches; and there are masses of black extravasated blood found beneath it. Occasionally the whole cavity has a slate-grey colour from the partial decomposition of the poison by the membrane itself; beneath this, the mucous coat may be found reddened. This grey tint of the mucous membrane has been considered by some to be indicative of the action of the poison on the living mucous membrane; but it is not always present. A case occurred at Guy's Hospital, in which the mucous membrane was simply inflamed: it much resembled the condition presented in cases of arsenical poisoning. The coats of the stomach are sometimes corroded, and so much softened that they cannot be removed from the body without laceration. Similar appearances have been met with in the small and large intestines, especially in the cæcum. In a case reported by Dr. Herapath, in which a scythe was taken, and death occurred on the ninth day, the mucous membrane of the stomach was softened, but there were no well-marked appearances of the action of the poison in this organ. The cæcum had been the seat of the most violent inflammation, the whole surface being of a deep black-red colour, and there were patches of sloughing in the coats. (Lancet, Dec. 27, 1845, p. 700.) In a case which occurred to Dr. Thomson of Perth, in which a man died forty hours after having swallowed two draçhes of corrosive sublinate in powder, the mucous membrane of the stomach, duodenum, upper portion of the ileum, and parts of the large intestines, were found of a bright red colour. This appearance was most marked at the cæcum and sigmoid flexure of the colon. The local action of the poison on the mouth and fauces was in this instance considerable. There was no suppression of urine. (Edinburgh Monthly Journal, Dec. 1851, p. 532.) Perforation of the stomach is very rare as an effect of this poison: there is, I believe, only one case on record. Certain morbid changes have been found in the urinary and circulating organs, and Mr. Swan states that he has found the ganglia and branches of the sympathetic inflamed; but these changes are not by any
means characteristic of this variety of poisoning. Appearances in the alimentary canal, like those just described, have been seen, not only where the case has terminated fatally in a few hours, but where it has been protracted for six, eight, and even eleven days. (Chaussier, Recueil des Mémoires, 363.)

Quantity required to destroy life.—This is a question which it is somewhat difficult to answer with any degree of certainty, since it is only by accident that the quantity taken can be ascertained, and the fatal effects must vary according to many circumstances. A child aged three years, died in twenty-three days from the effects of twelve grains of corrosive sublimate. The smallest dose which is reported to have destroyed life was three grains. This was also in the case of a child, and the quantity was accurately determined from the fact of its having been made up by mistake for three grains of calomel, which the physician intended to order. (This case is referred to in the Lancet, 1845, p. 297.) A very loose and imperfect report either of the same or of a similar case is given in the Annales d’Hygiène, 1833, i. 225. It is stated that three children lost their lives. It is probable that, under favourable circumstances, from three to five grains, or even less, would destroy an adult. Persons have been known to recover who have taken very large doses, when remedies were timely administered, or vomiting was produced. I have elsewhere reported a case in which a female who had swallowed nineteen grains recovered in a few days without a bad symptom. (Guy’s Hosp. Reports, Oct. 1850, p. 213.) A case of recovery after forty grains had been taken in whiskey under circumstances favourable to its fatal operation—i. e. on an empty stomach, is recorded by Dr. Andrews. (Cormack’s Journal, February 1845, 102.) The patient was a woman of sixty-five. The smallest dose required to destroy an adult, under ordinary circumstances, cannot, therefore, be determined at present from any reported facts. Judging from the effects produced by small quantities used medicinally, possibly the average fatal dose may not differ widely from that of arsenic—i. e. two to three grains.

Period at which death takes place.—In an acute case, an individual commonly dies in from one to five days: but death may take place much sooner or much later than this. A person has been known to die from the effects of this poison in eleven hours (Christison, 402) ; and in one instance of a child two years old, by whom twelve grains had been taken, death probably occurred in six hours. (Niemann’s Taschenbuch, 451.) A case is reported in which a child, aged seven, was killed in three hours by eighteen grains of corrosive sublimate. The shortest fatal case on record was communicated to me by Mr. Welch. The quantity of poison taken was not ascertained, but the man died in less than half an hour. (On Poisons, Corrosive Sublimate.)
CORROSIVE SUBLIMATE. CHEMICAL ANALYSIS. 105

Chemical analysis,—in the solid state.—We will first suppose that the poison is in a solid state, and in the form of a white powder. 1. A small quantity heated on thin platinum foil is entirely volatilized at a moderate heat—(care should be taken in performing this experiment)—in this property corrosive sublimate resembles arsenic, but it differs from arsenic in all other respects. 2. It is very soluble in water,—if the water be warmed, the powder will be dissolved instantly. 3. A small quantity of the powder dropped into a white saucer, containing a solution of iodide of potassium, is turned of a bright scarlet colour. 4. Dropped into potash in a similar way, it is turned of a yellow colour. 5. Into a solution of hydrosulphuric of ammonia, it is turned black. 6. When a few grains are rubbed on a clean surface of copper, with a mixture of one part of mariatic acid, and two parts of water, a bright silvery stain is produced, which is entirely volatilized by heat. If zinc or tinfoil be used instead of copper, the surface acquires a silvery lustre, and the metal becomes remarkably brittle. 7. When mixed with three or four parts of calcined carbonate of soda, and heated in a small tube similar to that employed in the analysis of arsenic, the metal is reduced; and a ring of bright globules of mercury is formed, while common salt remains in the tube. For the success of this experiment the materials must be quite dry, and the tube at first gently heated; any undecomposed corrosive sublimate that may be sublimed should be driven higher up, before finally applying a strong heat, so that the ring of mercury may not be obscured by it. This last experiment is conclusive of the nature of the substance; because mercury, being the only liquid metal, is the only metal which sublimes in globules. If the end of the reduction-tube, containing the fused chloride of sodium, left as a residue by the decomposition, be filed off, reduced to powder, and boiled with a little diluted nitric acid, a solution is obtained in which, on the addition of nitrate of silver, chlorine may be proved to exist. The analysis is then complete. The properties mentioned under 1, 2, and 5, are possessed in common by other bodies; but the other characters are peculiar to the persalts of mercury; and when the results agree, they render it absolutely certain that the powder must be a persalt of that metal. The action of nitrate of silver upon the solution of the residue will prove that the persalt must have been a chloride. There are therefore no objections to this mode of analysis.

In solution in water.—Corrosive sublimate is very soluble in water, forming a clear solution, which when concentrated, has a faintly acid reaction and a strong metallic taste. A few drops of the solution may be first gently evaporated on a slip of glass, and then set aside to crystallise. If it be corrosive sublimate, it forms slender opaque silky prisms, sometimes of considerable
length, and intersecting each other. When a weak solution of iodide of potassium is dropped on them, they acquire a bright scarlet colour, and chloride of potassium is formed. These characters, which may be obtained from the minutest crystal and only one drop of solution, prove that the body dissolved in water is corrosive sublimate; it is thus distinguished from every other mineral poison, and all other substances whatever.

Tests — 1. Potash.—On adding a small quantity of caustic potash to the solution, a reddish-coloured precipitate falls, becoming yellow by the addition of a large quantity of alkali. This precipitate, when washed, dried, and heated in a reduction-tube, yields a well-defined ring of metallic mercury. The filtered liquid will be found, on being tested with nitrate of silver, to contain chloride of potassium, thus proving that the mercury was combined with chlorine, and that the compound was soluble in water. 2. Chloride of tin.—On adding this test in rather large quantity to the solution, a white precipitate at first falls (calomel), becoming speedily of a slate-grey colour, and afterwards almost black. On warming the liquid it soon becomes clear, while a heavy precipitate, in great part formed of pure metallic mercury, falls to the bottom of the vessel. The mercury may be collected by pouring the liquid on a filter, and afterwards drying the filter; or its presence may easily be demonstrated by pouring the water carefully from the precipitate, and forcing down upon this a slip of bibulous paper; —the paper absorbs the water from the mercury, and the pressure condenses the metal into one or more well-defined globules. 3. Sulphuretted hydrogen gas.—This gives at first a precipitate, partly black and partly white (chlorosulphuret), becoming entirely black when the current of gas has been allowed to pass in for some time. Hydrogen sulphuret of ammonia gives a similar precipitate in the solution; thus clearly distinguishing corrosive sublimate from arsenic. The test acts equally in an acid solution of the salt. The precipitated black sulphuret of mercury, dried and heated with carbonate of soda or metallic silver, easily furnishes a ring of pure metallic mercury. 4. Precipitation by metals.—If we acidulate the liquid with a few drops of diluted muriatic acid, and introduce a slip of bright copper, or, what is better, fine copper-gauze, it is soon coated in the cold with metallic mercury, having more or less of a silvery lustre, especially on friction. On heating the copper in a reduction-tube, the mercury may be obtained in well-defined globules. 5. The galvanic test.—There are various ways in which galvanism may be applied to the detection of mercury or corrosive sublimate. Dr. Wollaston, on one occasion, employed an iron key and a guinea: he placed a drop of the suspected solution on a surface of gold, and touched it and the gold with the key: —the mercury was deposited on the gold in a bright silvery stain. The following is a ready method
of dissolving the metal: — Place a few drops of the sublimed
of copper on the surface of copper and gently heat it with a gas.
the copper through the solution with a blunt
Whenever the copper is heated by the metal, the sub-
tory is deposited, and on cooling the surface with
metallic and for analysis a little salt is used, which is imme-
the heat of a spirit-lamp. The experiment
may be illustrated by taking a strip of the metal and marking
on a copper-plate, and immersing them into the liquid.
any change of colour or tarnish is very apparent on the strip.
Mercury is deposited on both metals. A surface of copper
may be passed perhaps more distinctly than a surface of copper as a test
of the presence of mercury. Applied in a way to be properly
exposed, it will detect the metal when nearly every other
metal fails. Other tests have been proposed, but I am of
the opinion that they are not of much value, because the following are
suitable for every practical purpose.

1. A liquid containing copper matter. — The same process of
treatment of copper and waste matter are the same. If the

white lustre. There is no angularity, transparency, or crystalline character about this sublimate, as in the case of arsenic. When examined by the microscope, spherical globules are seen, which are perfectly opaque by transmitted light, and of a bright silvery lustre by reflected light.

In order to remove any doubt, the ring of glass on which the sublimate is deposited may be broken up and warmed in a wide tube with a few drops of nitro-muriatic acid. On evaporating to dryness at a very low temperature (corrosive sublimate being volatile), a residue having a prismatic crystalline character remains. These are crystals of corrosive sublimate reproduced from the globules of metallic mercury. When touched with a solution of iodide of potassium, they acquire a scarlet colour. In very fine sublimates this, or some corroborative experiments on their nature, are indispensably necessary.

The galvanic gold test may be thus applied: — Cut a slip of thin gold-foil, of about one inch in length and one-eighth of an inch in width; it should be just large enough to enter into a small reduction-tube. We then twist round this, in a spiral form, a slip of finely-laminated zinc; acidulate the suspected liquid with a few drops of diluted muriatic acid, and suspend the gold and zinc by a thread in the midst of it. Several such pieces may be at once suspended in the liquid. According to the quantity of mercury present, the gold will be coated with a grey-coloured deposit, either immediately or in the course of a few hours. If at the end of ten or twelve hours the gold retain its bright yellow colour, there is probably no mercury present in a dissolved form, or the quantity is exceedingly minute. Supposing the gold to have lost its colour, owing to its having become completely coated, we should remove it and dip it in ether, and afterwards in distilled water, to wash off any corrosive sublimate or organic matter adhering to it; it should then be dried in air without being allowed to touch any surface, and when dry introduced into a reduction-tube. The zinc may be in part dissolved; but as mercury is also deposited on this metal, whereby it is commonly rendered quite brittle, it may be introduced with the gold into the tube. On applying heat, a fine sublimate will soon appear in the cool part of the tube, which, if not perceptible to the eye, may be easily seen, by the aid of a common lens or of a microscope, to consist of minute globules of mercury. Fine wires of gold and zinc may be substituted for the foil. Let us suppose that the filtered liquid contains no trace of a mercurial salt; we must now direct our attention to the analysis of the insoluble matters separated by filtration. These may be boiled in distilled water; the liquid filtered, and tried by agitating it with one-third of its volume of ether. It will be found, when the analysis has not been long delayed, that most of the compounds which corrosive sublimate forms with organic matter, yield commonly
sufficient poison for detection, by boiling them in water. Should water fail in extracting the poison, the substance may be brought to dryness and heated with nitro-muriatic acid until all the organic matter is decomposed, and the surplus acid expelled. The residue may then be digested in water, and tested for mercury by the aid of copper-gauze or of gold and zinc.

Detection of absorbed mercury in the tissues.—The process suggested by Reinsch for the detection of arsenic is equally applicable to the detection of absorbed mercury in the tissues. Although Reinsch neither applied nor proposed it for this purpose, he found that in a clear solution of corrosive sublimate, when the quantity present did not form more than the fifty-thousandth part, globules of mercury might be obtained on copper. (Annales d’Hygiène, 1843, i. 445.) The plan which I have adopted is as follows:—The liver or other tissue is cut into small pieces, and boiled until the texture is entirely broken up, in a mixture of one part by measure of pure hydrochloric acid to six or seven parts by measure of distilled water. A small slip of copper-gauze at the end of a polished copper wire is first introduced. If it acquires a light grey colour, it is probable that mercury is present, and a larger piece of gauze is then introduced. If not immediately coated, the decoction is evaporated with the copper immersed in it. The coated gauze is cleansed, washed, dried (see ante, p.107), and then heated in a small tube. A minute ring of mercurial globules will be perceptible either to the unassisted eye or by the aid of a lens or microscope. The spherical form, opacity, and high metallic lustre by reflected light, are sufficient to identify the mercurial sublimate. If there should be any doubt, the corroborative test recommended in the preceding page may be employed. It must be remembered that this result merely proves the presence of mercury in the tissues, not of corrosive sublimate. The absorbed mercury may have been derived from some mercurial medicine innocently taken by deceased. In the case of Reg. v. Bacon (Lincoln Summer Assizes, 1857), sublimates of arsenic and mercury were obtained by this process from the viscera of deceased, the spherules of mercury being visibly intermixed with the octahedral crystals of arsenious acid, as seen by the microscope. Arsenic had been criminally administered to the deceased; with respect to the mercury, it was ascertained that she had taken medicinally two grains of calomel two days before her death. The body had been buried twenty-one months, and, as the analysis proved, some mercury was still remaining in the viscera after this long period. This is sufficient to show that this process is both delicate and certain.

A person may die from the effects of corrosive sublimate, and no mercury may be found in the tissues. A case of this kind occurred to me some years since at Guy’s Hospital; and another, in which the deceased died in fifteen days from a large dose of
corrosive sublimate in whiskey, has been reported by Dr. Geoghegan. On this occasion, although the local effects of the poison on the throat, stomach, and bowels, were of an intense kind, the viscera, on careful analysis, yielded no trace of mercury; it had been entirely eliminated. (See Med. Gaz. Vol. xlvi. p. 253.)

**Calomel.**

This substance, now called chloride of mercury, although commonly regarded as a mild medicine, is capable of destroying life, even in comparatively small doses. Several cases have been already referred to, in which excessive salivation, gangrene of the salivary organs, and death, have followed from the medicinal dose of a few grains. There is a case reported in the Medical Gazette (xviii. 484), in which a boy, aged fourteen, was killed in about three weeks by a dose of only six grains of calomel. It is singular that in this case neither the gums nor the salivary glands were affected; still, considering the effects of calomel in other instances, it seems most probable that the ulceration and gangrene of the face which followed were due to it. Pereira mentions the case of a lady who was killed by a dose of twenty grains of calomel: she had previously taken a moderate dose without a sufficient effect being produced. Sobernheim states that a girl, aged eleven, took in twenty-four hours eight grains of calomel, for an attack of croup, and died in eight days from inflammation and ulceration of the mouth and faucæ. In another instance, which occurred to Lesser, fifteen grains of calomel produced similar effects, with excessive salivation; and this patient also died in eight days. Meckel relates that twelve grains have destroyed life. (Lehrbuch, der Ger. Med. 267.) Two cases of death from calomel, in children, are recorded in the Registration returns for 1840.

There are many other fatal cases on record, and the facts leave no doubt that calomel may, in large doses, act as an irritant poison. It was supposed that these effects might be ascribed to this compound being adulterated with corrosive sublimate; but this supposition is not well founded. It has been also suggested that calomel might be converted into corrosive sublimate, by the free muriatic acid contained in the gastric secretions; but the very minute proportion in which this acid exists in the fluids of the stomach, according to Dr. Prout, renders this explanation improbable.

**White Precipitate. Ammonio-Chloride of Mercury.**

This is an irritant substance, although little is known concerning its effects. In January 1840, a young woman who had swallowed this substance, was received into St. Thomas's Hospital. She had mixed it and taken it in water,—but the quantity swal-
lowed could not be ascertained. The stomach-pump was employed, mucilaginous drinks and olive-oil were administered; and in the course of a few days she perfectly recovered. The symptoms under which she suffered were those of irritation of the stomach. Judging from this case, white precipitate does not appear to be a very active preparation; yet still it must be regarded as a poison. One instance of death from salivation produced by this compound is recorded in the Registration returns for 1840, in a child, aged seven; and within the last two years there have been several attempts at murder by the administration of this substance. Mr. Procter, of York, has communicated to me a case in which a woman recovered after having taken forty grains of this substance. At the Exeter Lent Assizes, 1855, a boy was convicted of the attempt to administer this poison to his father (Reg. v. Daniels). It is much used by the poor as a popular external remedy for the ringworm.

**Red Precipitate. Red Oxide of Mercury.**

This substance is poisonous, but instances of poisoning by it are very rare. The following case occurred at Guy's Hospital in 1833. A woman, aged twenty-two, who had swallowed a quantity of red precipitate, was brought in labouring under the following symptoms:—The surface was cold and clammy, there was stupor approaching to narcotism,—frothy discharge from the mouth, and occasional vomiting:—the vomited matters contained some red powder, which was proved to be red precipitate. There was considerable pain in the abdomen, increased by pressure; and there were cramps in the lower extremities. On the following day the fauces and mouth became painful, and the woman complained of a coppery taste. The treatment consisted in the use of the stomach-pump, and the free administration of albumen with gluten. She left the hospital four days afterwards, still under the influence of mercury. The quantity of oxide here taken was not ascertained. Soberneim relates a case in which a man, aged twenty-six, swallowed an ounce of red precipitate. He was speedily attacked with pain in the abdomen, nausea, purging, cramps, and general weakness. The vomited matters consisted of masses of mucus containing red precipitate. He continued to get worse, and died in less than forty-eight hours after taking the poison. On inspection, the mucous membrane was found eroded and inflamed in patches,—small particles of the poison being imbedded in it. The duodenum was in a similar state, and there was a large quantity of red precipitate in the contents of this intestine, as well as in the stomach. (Op. cit. 250.)

A common opinion exists among the vulgar, that this compound is possessed of very active poisonous properties; hence it is sometimes administered with criminal design.
CINNABAR.  VERMILION.  PERSULPHUROT OF MERCURY.

The term Cinnabar is applied to a dark and heavy compound of sulphur and mercury, while Vermilion is the same substance reduced to a fine powder. It is well known as a red pigment, and is often employed in colouring confectionery, wafers, &c. I have not been able to find any instance of its having acted as a poison on man. Orfila believes that it is not poisonous. It has, however, proved fatal to animals in the proportion of from thirty to seventy grains, even when applied externally to a wound. Cinnabar is sometimes used for giving a red colour to ointments, e.g., the sulphur ointment. In such cases the quantity is very small, and can do no injury even if swallowed.

Dr. Sutro has published a short abstract of a case in which the vapour of Vermilion applied externally produced severe symptoms. A woman, by the advice of a quack, applied this vapour to a cancerous breast. She employed three drachms of vermilion, covering herself with a sheet, so that the vapour should only reach the body externally. After three fumigations, she suffered from severe salivation and violent fever, which continued for four weeks. The right arm became oedematous. (Med. Times, Sept. 27, 1845, p. 17.)

CYANIDE OF MERCURY.

This is a substance which is but very little known except to chemists, yet it is an active poison, and has caused death in at least two instances. In April 1823, a person who had swallowed twenty grains of this compound (thirteen decigrammes), was immediately seized with all the symptoms of poisoning by corrosive sublimate, and died in nine days. There was continued vomiting, with excessive salivation, ulceration of the mouth and fauces, suppression of urine, purging, and, lastly, convulsions of the extremities. On inspection, the mucous membrane of the stomach and intestinal canal was extensively inflamed. (Orfila, i. 583.) Dr. Christison quotes a case in which ten grains destroyed life within the same period of time. (On Poisons, p. 427.) As a poison, the cyanide is probably not much inferior in activity to corrosive sublimate.

TURBITH MINERAL.  SUBSULPHATE OF PEROXIDE OF MERCURY.

Fatal cases of poisoning by this compound are by no means common. It is undoubtedly, although very insoluble in water, a strong irritant poison, and is capable of causing death in a comparatively small dose. A well-marked instance of its fatal operation was communicated to the Pathological Society by Mr. Ward, in March 1847. A boy, aged 16, swallowed one drachm of this preparation on the night of February 19th. It produced a burning
sensation in the mouth and throat, and vomiting in ten minutes. In about an hour there was paleness, with anxiety of countenance, coldness of surface, constant sickness, sense of heat and constriction in the throat, and burning pain in the stomach with cramps. The irritability of the stomach continued in spite of treatment, and after two days there was salivation with mercurial fever. The gums acquired a deep bluish tint and began to ulcerate. The patient died in about a week after he had taken the poison, without convulsions, and without suffering at any period from symptoms of cerebral disturbance. The principal appearances in the body were:—inflammation of the oesophagus, its mucous membrane at the lower part peeling off; the inner surface of the stomach near the two openings (cardia and pylorus) was covered with petechial spots; the small intestines were contracted, the inner coat reddened, and petechial spots were found, but chiefly in the large intestines. The parotid and submaxillary glands were swollen. Mercury was detected in the intestines. (See Med. Gaz. xxxix. 474.) From this account it will be perceived that turbith mineral produces effects somewhat similar to those of corrosive sublimate, but it is less active.

NITRATES OF MERCURY.

These are corrosive poisons which are used for various purposes in the arts. They are solid white salts, easily dissolved by cold water, especially if there be a little excess of acid present. The acid permistrate caused death in a case reported by Mr. Bigsley in the Medical Gazette (Vol. vi. p. 329). A butcher’s boy dissolved some mercury in strong nitric acid, and swallowed about a teaspoonful of the solution. Soon afterwards he suffered excruciating pain in the throat, gullet, and stomach:—there was great anxiety, with cold skin, small pulse, colic, and purging. He became gradually weaker, and died in about two hours and a half. On inspection, the throat, gullet, and stomach, were found corroded and inflamed. Although he survived so short a time, the mucous membrane of the stomach was of a deep red colour. I have elsewhere related a case in which the application of the permurate of mercury to the throat as an escharotic caused immediate death by asphyxia. (See Guy’s Hosp. Reports, Oct. 1850, 206.)

The acid nitrate of mercury has often been employed by accoucheurs as a local application in diseases of the neck of the uterus. In one instance in which it was thus used, the ordinary symptoms of mercurial poisoning showed themselves, and the patient appears to have suffered severely. (Medical Gazette, Vol. xlv. p. 1025.)

At the Leicester summer Assizes, 1857, a girl was charged with administering nitrate of mercury to her mistress (Reg. v. E. Smith). The evidence showed that the accused had put the
poison into some camomile tea prescribed for the prosecutrix. Only a small quantity was taken, as the tea had a nauseous taste. The symptoms were: — a burning sensation in the throat and stomach, violent vomiting with severe pain in the abdomen. By some extraordinary blunder, the girl was indicted under the statute which makes it penal to cast or throw or apply to any person any corrosive fluid, &c.: — and although the words “cause to be taken” are introduced, Cresswell J. ruled that this statute implied, external and not internal administration. As the indictment was wrongly laid, the accused was acquitted.

CHAPTER XI.

ON POISONING BY LEAD—SUGAR OF LEAD—SYMPTOMS—CHRONIC POISONING BY SUGAR OF LEAD—APPEARANCES AFTER DEATH—TREATMENT—QUANTITY REQUIRED TO DESTROY LIFE—CHEMICAL ANALYSIS—LEAD IN ORGANIC MIXTURES—CARBONATE OR WHITE LEAD—PAINTER’S COLIC—OXIDES—LITHARGE AND RED LEAD—ACCIDENTS FROM THE GLAZING OF POTTERY.

Sugar of Lead. Acetate.

This is more frequently taken as a poison than any of the other salts, although cases of acute poisoning by lead in any form are not common. The substance is commonly met with in solid heavy crystalline masses, white or of a brownish-white colour; it much resembles loaf-sugar in appearance, and has often been mistaken for it. It has also a sweet taste, which is succeeded by an astringent or metallic taste. It is very soluble in water. Four parts of distilled water at 60° will dissolve one part; it is much more soluble at a boiling temperature.

Symptoms. — Acetate or sugar of lead is by no means an active poison, although it is popularly considered to possess a virulent action. In medical practice it has often been given in considerable doses without any serious effects resulting. Dr. Christison states that he has given it in divided doses to the amount of eighteen grains daily for eight or ten days without remarking any unpleasant symptom whatever, except once or twice slight colic. (Op. cit. 555.) When, however, the quantity taken has been from one to two ounces, the following symptoms have been observed: — A burning pricking sensation in the throat, with dryness and thirst; — vomiting supervenes; there is uneasiness at the pit of the stomach, which is sometimes followed by violent colic. The abdomen is tense, and the parietes have been occasionally drawn
in. The pain is relieved by pressure, and has intermissions. There is in general constipation of the bowels. If any feces be passed, they are commonly of a very dark colour, indicative of the conversion of a portion of the lead to sulphuret. The skin is cold, and there is great prostration of strength. When the case is protracted, the patient has been observed to suffer from cramp in the calves of the legs, pain in the insides of the thighs, numbness, and sometimes paralysis of the extremities. The affection of the nervous system is otherwise indicated by giddiness, torpor, and even coma. A well-marked blue line has been noticed round the margin of the gums, where they join the teeth.

A remarkable series of cases of poisoning by acetate of lead has been reported by Mr. Bancks, of Stourbridge. (Lancet, May 5, 1849, p. 478.) By some accident, about thirty pounds of this substance were mixed as a miller's with eighty sacks of flour, and the whole was made into bread by the bakers and supplied as usual to their customers. It seems that no fewer than five hundred persons were attacked with symptoms of poisoning after partaking of this bread. In a few days they complained of a sense of constriction in the throat and the pit of the stomach, violent crampy pains round the navel, rigidity of the abdominal muscles, a dragging pain in the loins, and cramp with paralysis of the lower extremities. There was obstinate constipation, and the urine was scanty and of a deep red colour. The pulse generally was slow and feeble; the countenance anxious and sunken, frequently of a peculiar livid hue; tongue flabby; gums marked by a deep blue line. The surface was cool, and there was a general arrest of the secretions. Sickness was not a uniform symptom, and even when it existed at first, it speedily subsided. The mental faculties were undisturbed. Not one of the cases proved fatal, but among the more aggravated, there was great prostration, with collapse, livid countenance, universal cramps, numbness, and other alarming symptoms. After apparent convalescence, some of the symptoms returned in a more aggravated form without any obvious cause, and for a long time the patients were out of health. Inflammation was not observed. Purgative medicines were found most effectual in the treatment. The quantity of acetate of lead taken by each person could not be determined, as, on analysis, the samples of bread were found to be very unequally impregnated with the poison.

Even when the patient recovers from the first symptoms, the secondary effects often last for a considerable time. In two cases which occurred to Mr. Gorringle, two girls swallowed an ounce of the acetate of lead by mistake. Soon afterwards they felt a burning pain in the mouth, throat, and stomach, and in a quarter of an hour they vomited freely: in half an hour there was severe pain in the bowels, with purging. Under
treatment recovery took place. (Proe. Med. Journ. April 1846.) After the lapse of a year, they both suffered from severe pain in the pit of the stomach, which was tender on pressure. Nothing could be retained on the stomach; and, there was a choking sensation in the throat, with other constitutional symptoms. Paralysis and other symptoms of nervous disorder are, however, by no means necessary consequences. A girl who had swallowed sixty grains of acetate of lead, and suffered severely from the primary symptoms, recovered, and left the hospital in about three weeks without any paralysis or other disorder affecting the muscular system. (Lancet, April 4, 1846, p. 384.) This lead-palsy appears to be a more common consequence of chronic poisoning; i.e. of small doses repeated at intervals.

Appearances.—In one acute case related by Dr. Kerchhoffs, the mucous membrane of the stomach was found removed in several places, especially near the pylorus or intestinal opening; and most of the abdominal viscera were in a state of high inflammation. A trial for murder by this substance took place at the Central Criminal Court, in November 1844 (Reg. v. Edwards), but the details are so imperfectly reported as to throw no light upon the subject. The stomach and intestines are stated to have been found inflamed, and there were dark spots on the former. In animals, according to Dr. Mitscherlich, when the dose is large, the mucous coat of the stomach is attacked and corroded; this change appears to be purely chemical, and takes place in all the organs of the body with which the salt of lead comes in contact. If given in a small dose, it is decomposed by the gastric secretions, and exerts no corrosive power on the mucous membrane. When the acetate of lead was given in a state of albuminate dissolved in acetic acid, death took place with great rapidity; but on inspection, the stomach was not found corroded. This corrosive action belongs to the neutral salt, and is not manifested when the dose is small or when the poison is combined with an acid.

Quantity required to destroy life.—Nothing is accurately known concerning the fatal dose of sugar of lead. The facts already detailed show that it may be taken in comparatively large quantity without producing serious effects. Thirty and forty grains have been given daily, in divided doses, without injury. The following additional cases, in some of which recovery took place under very disadvantageous circumstances, prove that the acetate of lead is far from being a virulent poison:—Dr. Iliff met with an instance in which an ounce was swallowed in solution. The symptoms were pain in the abdomen resembling colic, vomiting, rigidity, and numbness. It was three hours before any remedies were used, and five hours before the stomach-pump was employed; but the person recovered. In the second case, also, an ounce was swallowed: sulphate of magnesia was
freely exhibited, and the stomach-pump was used. On the following morning there was slight excoriatiotion of the gums, which were white, with a sensation of heat in the throat: the bowels were relaxed, probably from the effect of the medicine. The day following, there were pains in the calves of the legs and thighs, with restlessness and thirst. In a week the woman perfectly recovered. In a case which occurred to Dr. Alderson, a man swallowed an ounce of the acetate of lead in a drunken fit. There was violent vomiting, and the man recovered.

**Chemical analysis. Acetate of lead as a solid.**—1. If a portion of the powder be heated in a small reduction-tube, it melts, then becomes solid; again melts, acquiring a dark colour, and gives off vapours of acetic acid; a black mass is left in the tube, consisting of carbon and reduced metallic lead. There is no sublimate formed. 2. It is very soluble in water, even when cold; common water is turned milky by it, from the presence of carbonic acid and sulphates. 3. A small portion of the powder dropped into a saucer containing a solution of iodide of potassium acquires a fine yellow colour. 4. When dropped into caustic potash it remains white. 5. Into sulphuretted hydrogen water or hydro-sulphuret of ammonia, it is turned black, in which respect it resembles the white salts of some other metals. 6. When the powder is boiled in a tube with diluted sulphuric acid, acetic acid, known by its odour and volatility, escapes. All these properties, taken together, prove that the salt is the acetate of lead.

**Acetate of lead in solution.**—If acetate of lead be presented in a state of solution, or if the solid salt be dissolved in water for the purpose of making further examination, we should note the following points. 1. A small quantity, slowly evaporated on a slip of glass, will give white and opaque prismatic crystals, which are turned yellow by iodide of potassium, and black by hydro-sulphuret of ammonia. The solution is said to be neutral; but I have found the common acetate of lead to have at the same time both an acid and (with rose paper) an alkaline reaction, i.e. reddening litmus-paper, and turning rose-paper green, a circumstance which might create some embarrassment in an analysis. 2. Caustic Potash, added to the solution much diluted with water, throws down a white precipitate, which is easily soluble in an excess of the alkali. 3. Diluted sulphuric acid produces an abundant white precipitate, insoluble in nitric acid, but soluble in muriatic acid and in a large excess of caustic potash. 4. It is precipitated of a bright yellow colour by the Iodide of potassium; the yellow iodide of lead is soluble in caustic potash, forming a colourless solution. It is also dissolved by concentrated muriatic acid. 5. Hydro-sulphuret of ammonia or sulphuretted hydrogen gas, produces a deep black precipitate, even
when less than the 100,000th part of the salt is dissolved. 6. Place a few drops of the solution on clean platina foil, acidulate it with acetic acid, then apply, through the solution, to the surface of the platina, a thin polished slip of zinc:—bright crystals of metallic lead are instantly deposited on the zinc; in this way a small quantity of lead may be detected.

Lead in organic mixtures.—The acetate of lead is precipitated by many organic principles, especially by albumen and tannic acid. Thus, we may have to analyse either an organic liquid containing lead, or a solid precipitate consisting of mucus or mucous membrane, intimately united to oxide of lead. The liquid must be filtered and examined by a trial test, i.e. either by adding to a portion, sulphuric acid, or by exposing bulbulous paper, dipped into the suspected liquid, to a free current of sulphuretted hydrogen gas. If the paper be not stained brown, there is no perceptible quantity of lead dissolved;—if it be stained brown, we dilute the liquid if necessary in order to destroy its viscidity, and pass it into a current of sulphuretted hydrogen until all chemical action has ceased. The black sulphuret of lead should be collected on a filter, washed and dried, then boiled for a quarter of an hour in a mixture of one part of nitric acid, diluted with four parts of water. This has the effect of transforming it, at least in part, to nitrate of lead soluble in water. This liquid, when filtered, may be evaporated to dryness, and the residue dissolved in water, or it may be at once cautiously neutralised by potash or ammonia (free from lead) and the tests added. If the quantity be too small for the application of all the tests, we may add sulphuric acid; should a white precipitate be formed, soluble in potash (free from oxide of lead), and this alkaline solution be again turned black by hydro-sulphuret of ammonia, this is sufficient evidence of the presence of lead. Should there be no lead dissolved, we must decompose the solid and insoluble matters in nitric acid slightly diluted, at a boiling temperature, filter, and test the filtered liquid, previously neutralised; or we may evaporate to dryness, destroy the organic matter by nitric acid, and redissolve the residue in water for testing.

Goulard’s Extract. Subacetate of Lead.

Symptoms and Effects.—This substance has caused death in at least four instances,—one in France and three in England. The symptoms produced are similar to those described in speaking of the former compound.

Goulard Water is nothing more than a mixture of one drachm and a half of this solution to a pint of water.

Carbonate of Lead.

Symptoms.—A case of poisoning by the carbonate of lead, was reported, in October 1844, to the Westminster Medical
C H R O N I C P O I S O N I N G B Y L E A D.

Society, by Dr. Snow. A child aged five years ate a portion not so large as a marble, ground up with oil. For three days he merely suffered from pain in the abdomen, and costiveness. On the third night, the child became rapidly worse, and there was vomiting. He died ninety hours after taking the poison, having passed some very offensive motions of a greenish-black colour (probably from admixture with sulphuret of lead) before he died. The mucous membrane of the stomach was much inflamed, and of a dark-red colour throughout. Lead could not be detected in the contents or tissues of the stomach, or in the matter vomited. It is remarkable that in this case so small a quantity should have proved fatal without exciting any marked symptoms of irritation in the first instance. There are many fatal cases of poisoning by the carbonate of lead in the human subject, but it has in these instances proved insidiously fatal by inducing Colica pictorum. They are to be regarded as cases of chronic poisoning.

Chronic poisoning. Colica pictorum, or Painter's Colic, may be considered as the chronic form of poisoning by carbonate of lead. The prominent symptoms are, violent pain in the bowels, constipation, emaciation, and paralysis. These effects sometimes rapidly follow exposure to emanations of lead. In another work (On Poisons. Lead), I have referred to cases in which colic and paralysis have arisen from a person sleeping in a recently painted room. In these instances, the emanations are received through the lungs. Dr. Alderson mentions several cases of a similar kind, and he calls this form acute paralysis from lead. (Lancet, Oct. 30, 1852, p. 391.) Among white-lead manufacturers, the carbonate finds its way into the system, either by the skin, the lungs, or both together;—it is diffused in a fine powder through the atmosphere, and thus enters into the lungs. It has been remarked in France, that in manufactories where the powder was ground dry, not only have the labourers suffered, but horses, dogs, and even rats have died from its effects. Since the practice has arisen of grinding the carbonate in water, cases of colica pictorum have not been so numerous.

Men employed in the manufacture of glazed cards are liable to attacks of this kind. There are numerous other cases in which lead, or its preparations, by mere contact with the skin, have been known to produce the usual results of lead-poisoning. Mr. Scanlan has communicated to me a case in which an infant was paralysed by reason of its having been washed with water containing a finely diffused oxide and carbonate of lead. Dr. Todd mentions the case of a man in King's College Hospital, who suffered from lead-palsy. He had been a potman, and the palsy was attributed to the constant handling of and cleaning of pewter pots. (Med. Gaz., Vol. xlviii. p. 1047.) Cosmetics and hair-dyes containing preparations of lead, may also produce dangerous effects. I have met with an instance, in which paralysis of the
muscles on one side of the neck arose from the imprudent use of a hair-dye containing litharge. Mr. Lacy has pointed out the injury to health which is likely to follow the use of white lead as a cosmetic by actors. (Medical Times and Gazette, Aug. 1852, p. 223.)

Symptoms.—The diagnostic symptoms of chronic poisoning by lead are well marked. There is first pain, with a sense of sinking commonly in or about the region of the navel (the seat of the colon). Next to pain there is obstinate constipation, retraction of the abdominal parietes, loss of appetite, thirst, fetid odour of the breath, and general emaciation. The skin acquires a yellowish or earthy colour, and the patient experiences a saccharine, stypic, or astringent taste in the mouth. A symptom of a peculiar nature has been pointed out by the late Dr. Burton, and others (Med. Gaz. xxi. 687), namely a blueness of the edges of the gums, where these join the bodies of the teeth: the teeth are of a brownish colour. Dr. Chowne states that from inquiry and observation, he considers that the presence or absence of this blue line is not connected with the administration or non-administration of lead (Lancet, Oct. 26, 1844). It has, however, been so frequently observed, that most pathologists now regard it as a well-marked pathognomonic symptom. A similar blue mark around the edges of the gums has been noticed in other cases of poisoning—or by mercurial preparations (ante, p. 113) ; and it is possible that in an advanced stage of chronic poisoning by lead it may be absent (see a case by Mr. Fletcher, Med. Times, Feb. 14, 1846, p. 395) ;—as where, for example, the individual has ceased to expose himself to emanations of lead. Many facts tend to show that it is an early symptom. This disease often kills the patient; and after death the large and small intestines are found much contracted, and their coats thickened. These changes have been especially observed in the colon.

For an instructive series of cases on chronic poisoning by lead, I must refer the reader to a paper, by Dr. de Mussy, published in the Dublin Quarterly Journal for May 1849; also Medical Gazette, Vol. xlv, page 260. These cases occurred at Claremont, in the members of the Royal Family of France. The effects were traced to the use of very pure water, which had acquired an impregnation of lead from contact with that metal, in the proportion of one grain to the imperial gallon. Thirteen out of thirty-eight persons were affected, and to such a degree, that the nails of the toes and fingers acquired a bluish discolouration. The children of the family did not suffer.

For an account of the circumstances under which water is liable to be poisoned with lead, and the effects produced by the use of such water, I must refer the reader to my work On Poisons.
Analysis.—Carbonate of lead is a solid white powder, insoluble in water, and immediately blackened by sulphuretted hydrogen or hydro-sulphuret of ammonia. 1. When heated on platina, it leaves a residue of yellow or orange-coloured oxide of lead, soluble in nitric acid. 2. The carbonate is easily dissolved with effervescence, by diluted nitric acid—a fact which shows that it contains carbonic acid. The oxide of lead, combined with nitric acid, may be readily detected by the tests already mentioned. This salt of lead is sometimes contained in very small proportion in loaf sugar, owing to the moulds in which the loaf is set to crystallise being painted with white lead, and a portion being thus mechanically taken up. This is a dangerous process, and ought to be prohibited.

Oxides of Lead.

The yellow oxide (massicot), and the brown oxide (peroxide), are but little known except to chemists. Litharge and minium or Red lead are, however, much employed in the arts, and have sometimes given rise to accidental poisoning. In October 1849, a woman who had swallowed two and a quarter ounces of the red oxide of lead was admitted into Guy's Hospital. No symptoms appeared for nine hours. There was then colicky pain, with urgent vomiting, followed by headache and general tenderness of the abdomen. She entirely recovered in about twelve days. (Guy's Hosp. Reports, October 1850, 209.)

Liquids used for culinary or dietetic purposes, especially if they contain a free acid, are liable to become impregnated with oxide of lead derived from the glaze of the vessel in which they are kept, and thus form poisonous salts. If vinegar be used, acetate of lead may result. Litharge-glaze is also easily dissolved by alkaline or fatty substances. The eating of dripping, or the fat of meat baked in a newly glazed vessel, has been known to give rise to slight attacks of colic; while the symptoms were referred by the party to some substance mixed with the food. A case in which the whole of the members of a family were thus poisoned will be found in the Lancet (July 4, p. 27). Another case of a similar kind is reported in the Medical Gazette (Vol. xlvii. page 659); and I am indebted to Mr. Procter of York, for the particulars of a case of some novelty, in reference to the contamination of food with lead. In July, 1852, four men partook of rhubarb-pie, and milk for supper; shortly afterwards, they were all seized with violent vomiting and intense colic. A portion of the vomited matters and food was examined by Mr. Procter, and lead was detected in them. The only source to which the lead could be traced, was the glaze of the pans in which the milk was kept. Lead pipes are largely used by publicans for the supply of beer. It is possible, therefore, if the beer is acid, and is allowed to remain some time in the pipe,
it may acquire an impregnation of lead, which might give rise to
colic and other unpleasant symptoms. When liquids of this
kind are impregnated with oxide of lead, the fact is imme-
diately known by their being turned of a brown colour by
hydrosulphuret of ammonia. All newly glazed vessels yield
traces of lead, more or less, on boiling in them pure acetic acid
or a solution of pure caustic potash. In this way the poisonous
nature of the glaze may be tested:—the oxide of lead being
dissolved either by the acid or the alkali. I have found com-
mon acetic acid itself containing, as impurity, two per cent.
of acetate of lead. Litharge was formerly much used to re-
move the acidity of sour wine, and to convey a sweet taste.
Acetate of lead, or some other vegetable salt of the metal, is
in these cases formed; and the use of such wine may be pro-
ductive of alarming symptoms. Many years since a fatal ep-
demic colic prevailed in Paris owing to this cause:—the adul-
teration was discovered by Fourcroy, and it was immediately
suppressed. Wine thus poisoned is known by its being
blackened by hydrosulphuret of ammonia. Snuff has been
adulterated with red lead: in one instance this mixture is
supposed to have caused death, and in another it gave rise to
serious symptoms. (Medical Gazette, xxxii. 138; also Ann-
ales d’Hygiène, 1831, ii. 197.)

CHAPTER XII.

COPPER—BLUE VITRIOL. SYMPTOMS. APPEARANCES AFTER
DEATH—TREATMENT. POISONING BY VERDIGRIS—SUBCHLOR-
HYDRE OF COPPER—CARBONATE—SCHEELE’S GREEN. CHEMICAL
ANALYSIS—TESTS—SPECIAL CHARACTERS OF THE SALTS.
COPPER IN ORGANIC LIQUIDS—IN ARTICLES OF FOOD.

All the salts of copper are poisonous. The two most commonly
known in commerce are the Sulphate of Blue vitriol, and the
Subacetate of Verdigris. This substance has been frequently
taken and administered in large doses for the purpose of suicide
and in attempts at murder. In the latter case the attempt has
been immediately discovered, owing to the very strong metallic
taste possessed by the salt. This would in general render it im-
possible that the poison should be taken unknowingly. With the
exception of these salts, poisoning by copper is usually the
accidental result of the common employment of this metal for
culinary purposes.

Sulphate of Copper.

Symptoms.—Sulphate of copper has been frequently given for
the purpose of procuring abortion. In doses of half an ounce
and upwards, it acts as a powerful irritant on adults, and a much
smaller quantity would suffice to destroy infants or children.
The salt speedily induces vomiting of the most violent kind; this
sometimes expels the poison from the stomach, and the
person recovers. The vomited matters are remarkable for being
generally of a blue or green colour; and broken crystals of blue
vitriol were discovered in them in a case in which the poison was
taken in a loosely pulverulent state. If the green colour of the
vomited liquids be owing to altered bile, it will not acquire a
blue tint on adding to a portion of the liquid a strong solution of
ammonia; but if it be caused by a salt of copper, this change of
colour will serve to indicate the fact. There is headache, pain
in the abdomen, with purging; the pain is of a colicky charac-
ter; and in aggravated cases there are spasms of the extre-
mities and convulsions. Dr. Percival met with a case in
which the most violent convulsions were produced in a young
female by two drachms of the sulphate of copper. Paralysis,
insensibility, and even tetanus, have preceded death, when the
poison was administered to animals. Among the symptoms
casually met with in the human subject, may be mentioned
jaundice. This has been observed to attend poisoning by the
sulphate, as well as by Scheele’s green. The medicinal dose of
sulphate of copper as an emetic, is from five to fifteen grains, and
as a tonic from one to three or four grains.

There are but few instances in which this poison has proved
fatal in the human subject. In 1836, a girl, sixteen months old,
pot some pieces of Blue stone (sulphate of copper), which were
given to her to play with, into her mouth. In a quarter of an
hour, the child vomited a bluish-green coloured matter, with
pieces of sulphate of copper in it; the skin was alternately cold
and hot, but there was neither purging nor convulsions. The
child died in four hours, and was insensible before death. (Me-
dical Gazette, xviii. p. 742.) Unfortunately no inspection of the
body was made; and yet, in the event of murder being com-
mitted by the administration of this substance, it will be some-
what unreasonably expected that medical witnesses ought to be
fully acquainted with the appearances produced by it!

Appearances. — In poisoning by the salts of copper, the mucus-
nous membrane of the stomach and intestines has been found more or
less thickened and inflamed in the few fatal cases which have
been hitherto examined: the membrane has been also found
eroded and softened in poisoning by verdigris. The gullet has
presented an inflammatory appearance. In a case of poisoning
by verdigris, quoted by Orfila, the stomach was inflamed and
thickened especially towards the pylorus (the intestinal opening),
the orifice of which, from the general thickening, was almost
obliterated. The small intestines were throughout inflamed, and
perforation had taken place, so that part of the green liquid was
effused into the abdomen. The large intestines were distended
in some parts, and contracted in others, and the rectum was
ulcerated on its inner surface. (Toxicologie, i. 623.) The lining membrane of the alimentary canal has been found throughout of a deep green colour, owing to small particles of verdigris adhering to it. It has been said that this is an uncertain character of poisoning by copper; since a morbid state of the bile often gives a similar colour to the mucous membrane of the stomach and duodenum. This objection cannot apply, when the green colour is found in the gullet, and throughout the intestines: and, under any circumstances, the evidence from the presence of a green colour would amount to nothing in the judgment of a prudent witness, unless copper were freely detected in the parts so coloured. It is well to remember, that the green stain, if due to copper, would be turned blue by ammonia. In death from arsenite of copper, the inflammatory appearances would probably be more strongly marked.

**Verdigris. Subacetate of Copper.**

This salt produces symptoms somewhat similar to those caused by the sulphate. There is a strong styptic metallic taste, with a sense of constriction in the throat, followed by severe colicky pains,—vomiting of a green-coloured liquid, and purging with violent straining. In a case reported by Pyl, a woman who swallowed two ounces of verdigris died in three days: in addition to the symptoms above described there were convulsions and paralysis before death. Niemann relates that a female, aged twenty-four, swallowed half an ounce of verdigris, and died under symptoms of severe irritation of the stomach in sixty hours. (Taschenbuch, 458.) In consequence of the great uncertainty of its operation, subacetate of copper is not employed internally.

**Subchloride of Copper.**

This is a rich green compound, known as Oxychloride or Brunswick Green. It is formed when common salt has been used in a copper vessel, and has thus given rise to accidental poisoning. It is also used as a pigment.

**Carbonate of Copper.**

A case of poisoning by this substance has been reported by M. Desgranges of Bordeaux. A man died in about six hours, as it was supposed from the effects of an unknown quantity of this poison which he had taken. He had sustained some violence from a fall, and when first seen he was in a state of complete stupor, and there was great coldness of the extremities. There was neither vomiting, purging, nor pain in the abdomen on pressure. On inspection, the gullet and stomach were covered with a green-coloured substance. The larger extremity of the stomach was vascular, and the mucous membrane of the intestines, as well as the liquid contained in them, was green. Car-
bonate of copper was found in the stomach, and traces of the metal existed in the urine—none was found in the blood. (Med. Gaz. xxi. 495.) It is remarkable that in this case there should have been neither vomiting nor purging. The poison seems to have acted more like a narcotic or cerebral than an irritant poison.

**Arsenite of Copper (Scheele’s Green).**

This compound, which is known under the name of Scheele’s —Emerald or Mineral—Green, contains about half its weight of arsenic. It is extensively used as a pigment in the arts, not only in the form of oil-paint, but for imparting numerous shades of green to the decorative papers of rooms. It is also improperly employed to give a green colour to wafers, the paper of adhesive envelopes, and articles of confectionery.

**Symptoms and Effects.**—A child, aged three years, swallowed a small capsule of Scheele’s green, used by his father as a pigment. In half an hour he complained of violent colic: there was frequent vomiting, with purging, cold sweats, intense thirst, and retraction of the parietes of the abdomen. The mouth and throat were stained of a deep green colour. Hydrated sesquioxide of iron was given: in about an hour, the vomiting and purging ceased, and soon afterwards the thirst and pain in the abdomen abated. The next morning the child was well. In another case, a child, a year old, ate several pieces of a cake of arsenite of copper used for colours. There was immediate vomiting of a liquid containing green-coloured particles of the arsenite, but there were no other urgent symptoms. White of egg, with sugared water, was given to it. After a short time the child became pale, and complained of a pain in the abdomen: the pulse was frequent, the skin cold, and there was great depression. Copious purging followed, soon after which the child recovered. (Galtier, i. 635.)

In the cases of two children poisoned by confectionery coloured with this substance, the chief symptom was incessant vomiting of a light green-coloured liquid, resembling bile diluted with water. Mr. Bulley, of Reading, who reports these cases (Medical Times, April 28, 1849, page 507), describes the symptoms as severe, although the quantity of poison swallowed was small. Under the use of an emetic of ipecacuanha the children recovered. A case was communicated to me in July 1849, by Mr. J. H. Hicks, in which a child, aged seven years, ate a slice of cake with a part of a green ornament on it. There was severe pain with thirst, burning sensation in the throat, with constant vomiting, but no purging. The child recovered in three days. The green pigment was found to be pure arsenite of copper mixed with sugar. (Guy’s Hosp. Reports, Oct. 1850, p. 218. See also Medical Gazette, Vol. xliii. p. 304.) In two cases which I examined in January 1853, a small quantity of a confectionery ornament, coloured with arsenite of copper, proved
fatal to two children. In a case which was the subject of a
criminal trial, this deadly compound was proved to have caused
the death of a gentleman by reason of its having been employed
to give a rich green colour to some blanc-mange served at a
public dinner:—the person who employed it considering that
emerald or mineral green was nothing more than an extract of
spinach! It led to death under the usual symptoms, and the
parties were convicted of manslaughter and sentenced to impris-
onment. (Reg. v. Franklin and Randall, Northampton Summer
Assizes, 1848.) Most of the colours used for confectionery are
of a poisonous nature: the pink colour given by cochineal or
madder is the only one which can be regarded as innocent.

Scheele’s green is extensively used to give a green colour to
paper-hangings, as it is one of the cheapest and most durable
greens. Dr. Traill reports a case in which a child aged three
years suffered severely from symptoms of arsenical poisoning,
owing to its having sucked some slips of paper coloured with
this green pigment; some of the paper, still retaining a green
colour, was passed in the motions. The child recovered (Edin-
burgh Monthly Journal, July 1851, page 1). This practice of
covering the walls of rooms with a large quantity of arsenic in
a loose and pulverulent state, is, I believe, liable to be attended
with considerable danger to health. I have been consulted in
several cases in which symptoms of chronic poisoning by arsenic
had apparently resulted from this cause alone. (See ante, Anse-
nic, p. 69, also p. 119, on the effects of lead-vapours.) The men
who manufacture and hang the paper, suffer also, as I am in-
formed, from inflammation of the eyes, and other symptoms,
apparently as a result of breathing the fine arsenical dust.

On some of these papers, the arsenical pigment is so lightly
laid, that the slightest friction is sufficient to remove it.
Numerous cases of illness, in which the cause is unsuspected,
are probably due to this pernicious practice of surrounding our-
selves with arsenic, in sitting and bed-rooms. In the kingdom
of Prussia, the use of arsenic in the manufacture of such papers,
is strictly prohibited. Among other uses of this noxious com-
pound, we find it employed for imparting a bright green colour
to the shelves of bakers’ and green-grocers’ shops. An incident
which occurred to myself will show that food may thus acquire
an arsenical impregnation. Several loaves of bread were sup-
plied to me, having upon the undercrust a quantity of a green-
coloured pigment, which on analysis turned out to be arsenite
of copper, containing about fifty per cent. of arsenic! On
inquiry, I found that the baker had recently painted the shelves
of his shop with this pigment, and the hot loaves placed upon
them had taken off a portion of the arsenical paint. It is easy
to conceive that an accident of this kind, if undetected, might
lead to serious results, and perhaps to very erroneous suspi-
cions. (Medical Times and Gazette, April, 1854, p. 326.)
Chemical analysis of the Salts of Copper.—The salts of copper are generally known by their colour: whether in the solid state, or in solution, they are either blue or green. The salts of one other metal are also of a green colour, namely nickel; but there are striking chemical differences between the salts of this metal, and those of copper. There are three very soluble salts of copper; two of these are blue, the sulphate and nitrate,—and one green, the chloride. The solutions of the cuprous salts have generally an acid reaction. The salt should be dissolved in water, diluted, and the following tests may then be applied.

Tests.—1. Solution of ammonia: this gives, in a solution of copper, a bluish-white precipitate, which is soluble in an excess of the test, forming a deep violet-blue liquid. 2. Ferrocyanide of potassium gives a rich claret-red precipitate;—if the quantity of copper be small, the liquid acquires merely a light-red colour; if large, the precipitate is of a deep red-brown colour, and of a gelatinous consistency. The ferrocyanide of potassium will act on the violet-blue solution produced by ammonia, provided it be much diluted or an acid added (sulphuric) to neutralise the ammonia. One portion of liquid may thus be tried by the two tests. 3. Sulphuretted hydrogen gas, or hydro-sulphuret of ammonia, gives a deep chocolate-brown precipitate, even in an acid solution; or if the copper be in small proportion merely a light-brown colour. 4. A slip of Polished Iron (a common needle) suspended by a thread in the liquid, is speedily coated with a layer of copper, even when the salt is in very small proportion. When much diluted, a drop of diluted sulphuric acid may be added. If the needle be left for some days in the liquid, the iron will be slowly removed, and a hollow cylinder of metallic copper will remain. This may be dissolved in diluted nitric acid, and tested with the foregoing tests; or the needle coated with copper, may be immersed in ammonia and exposed to air. The liquid then becomes slowly blue. Half a grain of sulphate of copper dissolved in sixteen ounces of water may be thus easily detected. It was long since proposed by Orfila to substitute Phosphorus for polished iron. This substance most effectually separates metallic copper from its salts, even when they are dissolved in organic liquids. 5. The Galvanic test.—If a few drops of the copper-solution be placed on platina-foil, slightly acidulated with a diluted acid, and the platina be then touched through the solution with a thin slip of zinc, metallic copper, of its well-known red colour, is immediately deposited on the platina. When the quantity of copper is small, there is merely a brown stain; but a blue liquid is formed by pouring on it ammonia, and exposing it to air. A coil of fine platina and zinc wire may be substituted for the foil.

Copper in organic liquids.—The oxide of copper is liable to be precipitated by certain organic principles, as albumen, fibrin, and mucous membrane: but some of these organic compounds are
easily dissolved by acids, or even by an excess of the solution of cupreous salt. A portion at least of the salt of copper is, therefore, commonly held dissolved. In such cases there is one peculiar character possessed by these liquids, i.e., they have a decidedly green colour even when the copper-salt is in a far less than poisonous proportion.

Separation by iron.—We first filter the liquid, and save the insoluble portions for a separate operation. We may use as a trial-test either a needle, zinc with platina wire, or add to a portion, oxalic acid: the last gives a bluish-white precipitate only when the copper is in a moderately large quantity, and the liquid is not very acid. If the needle be not coated with copper in the course of a few hours, it is certain that there is no detectable quantity of the poison present in the liquid.

Separation as a sulphuret.—If the copper-salt be present in large quantity, any of the trial-tests will indicate it immediately. We now destroy the viscosity of the liquid by diluting it if necessary; and pass into it a current of sulphuretted hydrogen gas in order to precipitate all the copper in the state of sulphuret. The black sulphuret may be collected, washed, dried, and then boiled in equal parts of nitric acid and water for a quarter of an hour. Nitrate and sulphate of copper are produced and dissolved,—a fact indicated by the liquid acquiring a rich blue colour; and some sulphur is at the same time separated. This liquid, when filtered, will give the usual reactions with the tests for copper.

Separation by platina.—The following is an expeditious and simple method of obtaining copper from organic liquids which contain the soluble poisonous salts of this metal. Having filtered the liquid, let a portion of it be placed in a clean platina capsule or crucible. A few drops of diluted sulphuric acid may be added, and a slip of zinc foil introduced. Wherever the platina is touched by the zinc, metallic copper is deposited; and after having in this way coated the platina-capsule, the surplus liquid may be poured off and the capsule well washed out. The copper is then dissolved in diluted nitric acid, and the tests may be applied after the excess of acid has been driven off by heat. This is perhaps the most expeditious and certain method of detecting a salt of copper in an organic liquid. It is, however, less delicate than the Iron-test.

Copper in articles of food.—The medico-legal history of poisoning by copper would be incomplete without some remarks on the action of certain articles of food on this metal when used for culinary purposes. This is not an infrequent form of accidental poisoning. The symptoms rarely appear until after the lapse of three or four hours. There is commonly nausea, with colicky pains and cramps in the limbs. It results from the experiments of Falconer and others, that metallic copper undergoes no changes
FOOD POISONED BY COPPER.

by contact with water, unless air be present, when a hydrated carbonate will be formed mixed with peroxide. If the water contain any acid, such as vinegar, or common salt, or if there be oily or fatty matter in contact with the metal, then the copper is more rapidly oxidized, and the liquor or fat acquires a green colour. If the copper vessel be kept perfectly clean, and the food prepared in it be allowed to cool in other vessels, there is no much risk of its acquiring a poisonous impregnation: nevertheless, no acid, saline, fatty, or oily liquid should be prepared as an article of food in a copper vessel. (See Ann. d'Hyg. 1832, i. 102.) Under the influence of heat and air, a portion of copper becomes dissolved, and the oily or other liquid acquires a green colour. The preparation of fruits, such as preserves, in copper vessels, is necessarily attended with some risk; for on cooling, a green crust is apt to form on the copper, just above the surface where the air and acid liquid meet. Some liquids while boiling appear to be but little liable to this impregnation:—thus, coffee, beer, milk and tea, have been separately boiled for two hours together, in a clean copper vessel, without any portion of the metal being taken up by either of the liquids. (See Falconer, on the Poison of Copper, 65, London, 1774, also Orfila, i. 611.) Accidents of this kind are usually prevented by lining the copper vessel with tin; but in very large boilers this plan is not always adopted—cleanliness alone is trusted to, and this, when properly observed, is a sufficient preventive. According to Passch, of Berlin, many of the accidents attributed to this form of cupreous poisoning are really due to other causes. (Casper's Vierteljahrschrift, 1852, B. i. H. i. S. 78.)

It has been stated that an impure alloy used by some of the lower grade of dentists has been so largely composed of copper, as to affect the health of those who have used the plates for the support of artificial teeth. The acid and salts in the saliva would facilitate the production of a poisonous salt of copper.

In the making of preserved fruits and vegetable pickles, the salts of copper (blue vitriol) are sometimes used for the purpose of giving a rich green colour. Many of the green pickles sold in shops are thus impregnated with the vegetable salts of this metal, to which they owe their bright grass-green colour. If the fruit or pickle be placed in a solution of ammonia, and copper be present, the substance is speedily turned blue. The iron test is, however, more delicate. A bright needle immersed in the pickle, or plunged into the solid, will be speedily coated with copper. The quantity of copper contained in such articles may not be sufficient to cause fatal effects; but serious symptoms of gastric irritation are sometimes produced, and in very young subjects these may assume an alarming character. (See Falconer, 87.)
CHAPTER XIII.

TARTARIZED ANTIMONY (TARTAR EMETIC), STIBIATED TARTAR.

Symptoms and effects.—When this substance is taken in a poisonous dose, a strong metallic taste is perceived in the mouth during the act of swallowing. There is great heat and constriction of the throat, with difficulty of swallowing, violent burning pain in the region of the stomach, followed by incessant vomiting, profuse purging, faintness, and extreme depression. The pulse is small and rapid, sometimes imperceptible; the skin cold, and covered with a clammy perspiration; and the respiration is painful. Should the case prove fatal, death may be preceded by giddiness, insensibility, great prostration of strength, and sometimes violent spasms of the muscles of the extremities. Such are the symptoms in an acute case of poisoning by this substance.

The quantity actually required to destroy life is unknown. It will probably depend in some degree on whether active vomiting and purging have been excited or not; for these symptoms have not been present in all cases. Doses of from twenty grains to one ounce have been taken without destroying life; although alarming symptoms of irritation have followed. In one case related by Orfila, a man, aged fifty, took forty grains of tartarized antimony, and died in about four days. This was the only one out of five cases of poisoning by this substance quoted by Orfila, which proved fatal. (Orfila, i. 480.) Dr. Beck mentions a case in which fifteen grains of tartarized antimony in solution killed a child in a few weeks: vomiting and purging ensued, followed by convulsions and death. This case proves that a patient is not always saved by vomiting and purging:—the fatal effects on such an occasion are probably due to rapid absorption. (See also Medical Gazette, Vol. xliv. p. 334.) Dr. Pollock has recorded a case in which an adult was killed in ten hours by a dose of one drachm in spite of early and violent vomiting. (Med. Gaz. Vol. xliv. p. 801.) In two cases observed by Mr. Hartley, which will be presently described, ten grains killed each child in a few hours. A dose of four grains, however, has been known
to produce alarming symptoms. Dr. Lambert, who reports the case in Casper's Wochenschrift, states that this dose gave rise to violent pain in the abdomen, vomiting, and purging. The patient then fell into strong convulsions, which lasted half an hour. He became speechless,—no pulse could be perceived, the skin was cold, and it was supposed that he was dead. Stimulating frictions and poultices were employed, and he slowly recovered in about fourteen days. This poison might, in a much smaller dose, occasion death by reason of its exerting a depressing influence on the action of the heart. Aged persons, or those who are debilitated by disease, might die under these circumstances from a dose or doses which would produce no injury to strong and healthy adults. The effects, however, should be clearly traced to the action of the poison, and not be owing to exhaustion as a result of disease. In February, 1853, Mr. Wakley referred to me, for examination, a case in which it was supposed that two doses of antimonial wine, equal to about three grains of tartar emetic, had caused the death of a man who was in a diseased condition, by its remote effect upon the heart. No trace of poison was found in the stomach or tissues, there were no symptoms to indicate poisoning, and under these circumstances death could not be reasonably attributed to the medicine. The man died in about twenty hours afterwards, probably as a result of the exhaustion of the vital powers from disease, and not from the action of this substance.

In a case reported by Mr. Freer, of Stourbridge, a man, stat. 28, swallowed two drachms of tartarized antimony by mistake for Epsom salts, and recovered from its effects. An hour after the poison had been taken, he was found in the following state:—his pulse imperceptible; tongue dry and red; countenance cold and livid, bathed with clammy perspiration, and indicative of great suffering; violent pain in the stomach and over the whole of the abdomen, with constant spasmodic contraction of all the muscles, particularly of the abdomen and upper extremities. The fingers were firmly contracted, and the muscles quite rigid. He vomited only once, about half an hour after he had swallowed the poison, and after this he had constant involuntary aqueous purging. An emetic of mustard and salt was given to him, and this produced violent vomiting of bilious matter. Green tea, brandy, and decoction of oak-bark, were freely given. The cramps, vomittings, and aqueous purging, continued for six hours. The symptoms then became mitigated, and he gradually recovered, suffering chiefly from profuse night perspirations. (Lancet, May 22d, 1847, 535.) This case is remarkable for the anomalous character of the symptoms, as, in the absence of active vomiting, an emetic was actually required to be given,—also for the recovery of the individual after a very large dose of the poison. In the Association Medical Journal for April 1, 1853, at page 281, will be
found reported a case in which a physician took half an ounce of tartarized antimony by mistake for Rochelle salts. Vomiting did not come on for half an hour; but under good medical treatment he recovered in a few days. In another case fifty-five grains caused the death of an adult in sixteen hours. In one instance a small dose of this substance caused death by producing intestinal haemorrhage. (See the same Journal, June 10, 1853, p. 513.)

Dr. Gleaves, U.S., has related, in the Western Journal of Medicine and Surgery, the following case:—A young man swallowed by mistake a tablespoonful of tartarized antimony (= about 478 grains). In an hour after, he was speechless, pulseless, and apparently dying. Although he drank freely of cold water, and irritated his throat repeatedly with his finger, no vomiting had occurred. During the first three hours he vomited only two or three times, and the matter ejected was chiefly the warm water taken to favour vomiting. After the lapse of two hours there was the most violent purging. In seven hours this ceased, and there was great thirst, with a sense of burning pain in the throat, gullet, stomach, and bowels. There was also great irritability of the stomach, and the vomited matters were tinged with blood. On the following day the vomiting continued, but the purging was arrested. The throat was covered with pustules: there was pain in passing the urine, which was copious. On the third day, the whole of the body was covered with genuine tartarized antimony pustules. These began to heal, and the patient to recover, in about two weeks. (Medical Times, Jan. 24, 1846, p. 127.) This is the only case of poisoning by tartarized antimony in which vesicular eruptions on the skin are stated to have been observed. It is otherwise remarkable for recovery from so large a dose, considering that but little of the poison could have been expelled in the first instance by vomiting.

Appearances after death.—The following cases, reported by Mr. Hartley, show the nature of the appearances likely to be found after death:—Two children, a boy aged five years, and a girl aged three years, each swallowed a powder containing ten grains of tartarized antimony mixed with a little sugar. It was stated that, in twenty minutes after taking the powders, they were seized with violent vomiting and purging, and great prostration of strength, followed by convulsions and tetanic spasms: there was also great thirst. The boy died in eight hours, and the girl in twelve or thirteen hours, after swallowing the dose. The bodies were inspected between four and five days after death. In that of the boy there was effusion of serum in the right pleura; the lower lobe of the right lung posteriorly was redder than natural, and the peritoneum was injected from recent inflammation. The mucous membrane of the duodenum was inflamed, and covered with a whitish yellow viscid secretion; this was observed throughout the intestinal canal, although the colour was of a deeper yellow in the large intestines; there was no ulce-
ration. The peritoneal coat of the stomach was inflamed. The mucous membrane of this organ was much inflamed, especially about the larger curvature and at the cardiac orifice: there was no ulceration. The contents (about two ounces and a half of a dark grumous fluid, having a slightly acid reaction) were adherent to it; and in one case there was a patch of lymph. The tests used did not indicate the presence of antimony. With regard to other appearances, the tongue was covered with a white fur, and appeared soddened; the fauces were not inflamed; the windpipe and gullet had a natural appearance. On opening the cranium, the dura mater was found vascular; the longitudinal sinus contained a coagulum of lymph, and but little blood. The vessels of the surface of the brain were much injected with dark blood, the whole surface having a deep purple colour. Every portion of the brain, when cut, presented many bloody points. The cerebellum and medulla oblongata were also extremely vascular; there was no effusion in the ventricles or at the base of the brain. In the body of the girl, the morbid appearances were similar; there were also patches resembling the eruption of scarlatina on the arms, legs, and neck. The arachnoid membrane was more opaque than usual; and on the mucous membrane of the stomach, where the inflammation was greatest, were two or three white spots, each about the size of a split pea, which appeared to be the commencement of ulceration. (Lancet, April 25, 1846, 460.) A girl, 9t, 16, swallowed a dose of tartarized antimony, amounting to from forty to sixty grains. There was severe vomiting in a quarter of an hour, and this was soon followed by purging: these symptoms continued for about three hours. She also complained of pain, and a burning sensation down the oesophagus. The vomited matters were of a dark colour. On the following morning she had recovered from the severity of the symptoms; but in the afternoon there was a relapse. She continually threw her head back, and screamed: the skin was warm and moist: the pupils were dilated; and the knees drawn up. She died in about thirty-six hours after taking the poison, and during the six or eight hours previous to her death she was quite delirious. An inspection was made thirty-six hours after death. The throat appeared swollen: the lungs were slightly congested: the heart was healthy, and contained about six drachms of fluid blood. The stomach contained sixteen ounces of a thick bloody fluid: at the greater extremity the coats were softened, and blood was effused under the mucous coat in several places. The small intestines contained a similar fluid, with much mucus; but there was no appearance of inflammation. Only slight traces of the poison were found in the contents of the stomach by the usual tests, the greater part having probably passed off by vomiting and purging. (Mr. Beale in Lancet, Jan. 21, 1854.) In animals poisoned by this
substance, it is common to find general inflammation of the alimentary canal.

It has been hitherto supposed that the cases in which this poison has proved fatal have been few; but I have elsewhere reported thirty-seven, of which sixteen were fatal. The smallest fatal dose was in a child,—three quarters of a grain, and in an adult, two grains; but in this case, there were circumstances which favoured the fatal operation of the poison (Guy's Hospital Reports, Oct. 1857).

**Chronic poisoning.**—A good account of the effects produced by this poison, given at intervals in small doses to healthy persons, has been published by Dr. Mayerhofer (Heller's Archiv, 1846, pts. 2, 3, 4, page 100, et seq.). The principal symptoms are,—great nausea, vomiting of mucous and bilious liquids, great depression, watery purging, followed often by constipation of the bowels,—small, contracted, and frequent pulse,—loss of voice and muscular strength,—coldness of the skin, with clammy perspiration, and death from complete exhaustion. Several cases have recently occurred in this country, which show that tartarized antimony has been thus criminally used. In addition to the cases of Ann Palmer and J. P. Cook, there are those of Reg. v. McMullen, Liverpool Summer Assizes, 1856; Reg. v. Freeman, Drogheda, Spring Assizes, 1857; and Reg. v. Hardman, Lancaster Summer Assizes, 1857.) (See Poisons; also, Guy's Hospital Reports, October, 1857.)

**Chemical analysis. Tartarized antimony as a solid.**—In the state of powder.—1. Tartarized antimony is easily dissolved by water,—it is taken up by fourteen parts of cold, and two of boiling water; the solution has a faint acid reaction, and an acid caustic taste; it is decomposed by long keeping. It is insoluble in alcohol. 2. The powder dropped into hydro-sulphuret of ammonia is turned into a deep reddish-brown colour, and is thereby known from other poisonous metallic salts. 3. When heated in a reduction-tube, it is charred, but does not melt before charring, like the acetate of lead. The metal is partially reduced by the carbon of the vegetable acid, and the decomposed mass has a greyish-blue metallic lustre. I have not found that a metallic sublimate is produced in this experiment by the heat of a spirit-lamp. 4. When boiled with muriatic acid and metallic copper, a grey deposit of antimony takes place on that metal. The colour of the deposit is violet if the quantity be very small, and the deposit is black and pulverulent if very large.

**Tartarized antimony in solution.**—1. On slowly evaporating a small quantity on a slip of glass, it will crystallise in tetrahebra. If obtained from a very diluted solution, this crystallisation is confused, and resembles that of arsenic. 2. Diluted nitric acid added to the solution, throws down a white precipitate (sub-
nitrates of antimony); the other two mineral acids act in the same way; but, as they precipitate numerous other metallic solutions, there are objections to them which do not hold with respect to nitric acid. The white precipitate thus formed possesses the remarkable property of being easily and entirely redissolved by a solution of tartaric acid; it is also soluble in a large excess of nitric acid, so that if much of the test be added at once, no precipitate is produced. 3. Ferrocyanide of potassium does not precipitate the solution, whereby tartarized antimony is known from most other metallic poisons. 4. Hydrosulphuret of ammonia or sulphuretted hydrogen gas, produces in the solution a reddish orange-coloured precipitate, differing in colour from every other metallic sulphuret.

The foregoing tests, it will be observed, merely indicate the presence of oxide of antimony, — but this is in reality the poison which we have to seek, — the cream of tartar with which it is combined being merely the vehicle; and in a case of poisoning, this is no more the object of medico-legal research than if it were the vehicle for the administration of arsenic or corrosive sublimate. It is, besides, well known that tartarized antimony is the only salt of the oxide of antimony in a soluble form which is likely to be met with in medicine or chemistry. Should it be required to prove the presence of cream of tartar, this may be done by filtering the liquid from which the oxide of antimony has been entirely precipitated by sulphuretted hydrogen gas. On evaporating this liquid, the cream of tartar may be obtained.

In liquids containing organic matter,—Tartarized antimony is precipitated by tannic acid in all its forms, but not readily by albumen or mucus membrane; therefore it may be found partly dissolved in the liquids of the stomach, provided no antidote has been administered. The liquid must be filtered, and then strongly acidulated with tartaric acid. A current of sulphuretted hydrogen gas is now passed into it, until there is no further precipitation. The sulphuret is collected, washed, and dried. If it be the sulphuret of antimony, it will have an orange-red or brown colour, and will, when dried, be dissolved by a small quantity of boiling muriatic acid (forming sesquichloride of antimony) with the evolution of sulphuretted hydrogen. The boiling should be continued for several minutes. On adding this solution to a large quantity of water, a dense white precipitate of oxychloride of antimony (powder of Algaroth or Algarotti, Mercurius Vitæ) falls down. This is characteristic of antimony. If it be objected that nitrate of bismuth undergoes a similar change when dropped into water, hydrosulphuret of ammonia will easily enable us to distinguish the two metals; the antimonial precipitate is turned of an orange-red by that solution, while the bismuthic precipitate is turned of a deep black. A medical jurist must remember that the discovery of tartarized antimony in the con-

\[ \text{\textit{K 4}} \]
tents of a stomach is by no means a proof of its having been taken or administered as a poison; since it is frequently prescribed as a medicine, and often taken as such by persons of their own accord. We could only suspect that it existed as a poison, or had caused death, when the quantity present was large, and there were corresponding appearances of irritation in the alimentary canal. The presence of any quantity, if not lawfully administered as a medicine, is always a suspicious fact, and demands explanation. In two cases of criminal administration in small doses, the quantity found in each body did not exceed three grains. The discovery of it in a medicinal mixture would not of itself be evidence of an intent to poison.

In the tissues.—Orfila has successfully applied Marsh's process for arsenic to the detection of antimony in the tissues. (For the details of this process I must refer to my work On Poisons.) Reinsch's process also serves to separate antimony from the soft parts when they are boiled for some time in muriatic acid and water. The copper acquires a violet-blue or steel-grey colour (resembling arsenic), according to the proportion present. The deposit on copper does not yield a sublimate of octahedral crystals like arsenic. Its antimonial nature may be proved by a process suggested by Dr. Odling. The coated copper, either foil or gauze, is boiled in water tinted with permanganate of potash, and rendered feebly alkaline by potash. When the pink colour of the permanganate is discharged, the liquid is filtered, acidulated with hydrochloric acid, and treated with a current of sulphuretted hydrogen. If the deposit on copper was antimonial, there will be produced a light orange-yellow precipitate of sulphuret of antimony. This separation of antimony from the tissues does not necessarily indicate that it has been criminally administered or has caused death; but its presence must be reasonably accounted for, as antimony may have been unlawfully administered. In several cases of suspected death from poison, deposits on copper, evidently of an antimonial nature, have been obtained from the liver or tissues. On inquiry, it has been found that antimonial medicines had been taken shortly before death.

CHLORIDE OF ANTIMONY. SESQUICHLORIDE OR BUTTER OF ANTIMONY.

Symptoms and appearances.—In 1836, a boy, aged 12, swallowed by mistake for ginger beer four or five drachms of a solution of butter of antimony. In half an hour he was seized with vomiting, which continued at intervals for two hours. There was faintness, with general weakness, and great prostration of strength. Remedial means were adopted, and the next day the chief symptoms were heat and uneasiness in the mouth and throat, with pain in swallowing. There were numerous abrasions on the mucous membrane of the mouth and fauces; and
POISONING BY ZINC.

there was slight fever, from which the boy quite recovered in about eight days. Another case of recovery from a dose of an ounce is reported in the Lancet, Feb. 26, 1848, p. 230.

The only fatal case which I have met with was communicated to me by Mr. Mann, of Bartholomew Close. An army surgeon swallowed, for the purpose of suicide, from two to three ounces by measure of chloride of antimony. About an hour afterwards he was seen by Mr. Mann. There was entire prostration of strength, with coldness of skin, and incessant attempts to vomit. The most excruciating griping pains were felt in the abdomen; and there was a frequent desire to evacuate the bowels, but nothing was passed. In the course of a few hours reaction took place, the pain subsided, and the pulse rose to 120. There was now a strong disposition to sleep, so that he appeared as if labouring under the effects of a narcotic poison. In this state he continued until he died,—ten hours and a half after he had swallowed the poison. On inspection the interior of the alimentary canal from the mouth downwards to the jejunum, presented a black appearance, as if the parts had been charred. In general, there was no mucous membrane remaining, either on the stomach or elsewhere; only a flocculent substance, which could be easily scraped off with the back of the scalpel, leaving the submucous tissue and the peritoneal coat. All these parts were so soft that they were easily torn by the fingers.

Chemical analysis.—If any portion of the chloride be left in the vessel, it may be tested by adding a few drops to a large quantity of water, when the whitish-yellow oxchloride of antimony will be precipitated; the supernatant liquid will contain muriatic acid, which may be detected by nitrate of silver. It has been already observed, that the only objection to this mode of testing is, that the salts of bismuth are also decomposed by water; but the precipitate in this case is insoluble in tartaric acid, and is blackened by hydrosulphuret of ammonia; while in the case of antimony it is soluble in that acid and is changed to an orange-red colour by the hydrosulphuret.

PREPARATIONS OF ZINC. Sulphate of Zinc. White Vitriol or White Copperas.

Symptoms and appearances.—The symptoms produced by an over-dose of sulphate of zinc are pain in the abdomen and violent vomiting, coming on almost immediately, followed by purging. After death, the stomach has been found inflamed. The sulphate appears to act as a pure irritant; it has no corrosive properties. This salt may cause death indirectly as the result of exhaustion from violent vomiting, when an ordinary dose has been given to a person already debilitated by disease. (Med. Times and Gaz., July 16, 1853, p. 78.) Dr. Gibb has reported
a case of poisoning by this substance, in which a lady recovered after taking sixty-seven grains. (Lancet, May 17, 1856.)

**Chemical analysis.**—The pure sulphate is seen in white prismatic crystals, closely resembling in appearance sulphate of magnesia and oxalic acid; from oxalic acid it is distinguished by remaining fixed when heated on platina foil,—from the sulphate of magnesia, by tests applied to its solution. It is readily dissolved by water, this fluid taking up about one-third of its weight at common temperatures. Analysis of the solution.—The solution in water has a slightly acid reaction. The following tests may be used for the detection of oxide of zinc. 1. *Ammonia* gives a white precipitate, soluble in an excess of the alkali. 2. *Sesquicarbonate of ammonia*, a white precipitate, also soluble in a large excess of the test. 3. *Ferrocyanide of potassium*, a white precipitate. 4. *Sulphuretted hydrogen* and hydrosulphuret of ammonia, a milky-white precipitate, provided the solution be pure and neutral, or nearly so. If the solution be very acid, sulphuretted hydrogen produces no effect whatever.

**In organic mixtures.**—If the sulphate of zinc be dissolved, we may pass into the solution a current of sulphuretted hydrogen gas; the presence of zinc is immediately indicated by a milky-white froth—the sulphuret may be collected, and decomposed by boiling it with muriatic acid. The solution may be then tested for zinc.

**Chloride of Zinc.**

The Chloride of zinc is sold to the public as a disinfectant under the name of “Sir W. Burnett’s Fluid.” This is a highly concentrated solution of the pure or sometimes impure chloride of the metal; it has been taken by accident in several cases, and in one instance was supposed to have been criminally administered as a poison.

**Symptoms.**—In a case reported by Dr. Stratton, about two ounces of a solution containing only twelve grains of the chloride were swallowed. The patient immediately felt pain and nausea; vomiting followed, and she recovered, but suffered from some indisposition for three weeks. In a second case, a wineglassful, equivalent to at least two hundred grains of solid chloride, was swallowed. The man instantly experienced burning pain in the gullet, burning and gripping pain in the stomach, great nausea, and coldness. Vomiting came on in two minutes; the legs were drawn up to the body; there was cold perspiration, with other signs of collapse. The man perfectly recovered in sixteen days. (Ed. Med. and Surg. Journal, Oct. 1848, p. 335; and British American Journal, Dec. 1848, p. 201.) Other cases show that the concentrated liquid has a strong corrosive action locally, destroying the membrane of the mouth, fauces, gullet, and stomach. There has been frothing of the mouth, with general
lividity, and coldness of the skin. In a case in which only a mouthful of the fluid had been swallowed, the patient experienced giddiness and loss of sight, with immediate burning heat in the stomach: vomiting and purging came on, and the former symptom continued for a week. There was so much irritability of the stomach for a period of three weeks, that the patient became greatly reduced. Among the early symptoms was loss of voice, which did not return for five weeks. (Med. Times, Oct. 11, 1851, p. 382; and Nov. 8, 1851, p. 497.) Dr. R. Hassall has reported a case in which the nervous symptoms were strongly marked, and were of a peculiar kind. Three ounces of "Burnett’s Fluid" were swallowed. There was immediately a sense of constriction in the throat, with a hot burning sensation in the stomach. There was no pain in the mouth, and there was no appearance of corrosion in this cavity or on the lips. There was incessant vomiting, the vomited matters consisting of thick mucus, streaked with blood, and some portion of mucous membrane was discharged. There was no purging until the third day, when the discharges from the bowels had a coffee-ground appearance. After the lapse of a fortnight a train of nervous symptoms set in, indicated by a complete perversion of taste and smell. The patient appears to have recovered in about three months. (Lancet, Aug. 20, 1853, p. 159.)

Appearances after death.—Out of five cases of poisoning by this substance, only one proved fatal; this was in the case of an infant aged fifteen months. The lining membrane of the mouth and throat was white and opake. The stomach was hard and leathery, containing a liquid like curds and whey. Its inner surface was corrugated, opake, and tinged of a dark leaden hue. The lungs and kidneys were congested. The fluid of the stomach was found to contain chloride of zinc. (Med. Times, July 13, 1850, p. 47.) These facts show that the concentrated solution of chloride of zinc is both a corrosive and an irritant poison, exerting also a powerful action on the nervous system. In a case which proved fatal at Guy’s Hospital, in 1856, the coats of the stomach were excessively thickened, and had a leathery consistency. It may destroy life by producing stricture of the oesophagus, or by its chemical action on the lining membrane of the stomach leading to a loss of power of digestion, emaciation, and exhaustion.

Analysis.—The chlorine may be detected by nitrate of silver—the zinc by the tests above described. (See Sulphate.) All the samples which I have examined contained iron.

Carbonate of Zinc (Calamine).

This compound does not appear to have any poisonous action; and it would probably require to be given in large quantity to
produce any effect. Carbonate of zinc is the white substance which is formed on the metal when long exposed to air and moisture. Its effects may become a subject of investigation as a matter of medical police; since zinc is now much used for roofing, and also in the manufacture of water-pipes and cisterns. (See Ann. d’Hyg. 1837, ii. 353; also Edinburgh Monthly Journal, Aug. 1850, p. 181.)

**Preparations of Tin.**

The only preparations of this metal which require to be noticed as poisons are the Chlorides, or Muriates, a mixture of which is extensively used in the arts, under the name of Dyer’s Spirit. The salts may exist in the form of whitish-yellow crystals; but more commonly they are met with in a strongly acid solution in water. They are irritant poisons; but so seldom used as such, that only one death occurred from them in England and Wales during a period of two years.

**Preparations of Silver.**

Nitrate of Silver. Lunar Caustic. Lapis Infernalis.—This substance, which is commonly met with in small sticks of a white or dark grey colour, is readily soluble in distilled water; in common water it forms a milky solution. It acts as a powerful corrosive, destroying all the organic tissues with which it comes in contact. There are at least two cases on record in which it has proved fatal in the human subject: one of these occurred in 1837-8, but the particulars are unknown. The symptoms come on immediately, and the whitish flaky matter vomited is rendered dark by exposure to light. Dark-coloured spots on the skin will also indicate the nature of the poison.

**Preparations of Gold.**

Perchloride.—This is the only preparation of gold which requires notice. It is a powerful irritant poison, acting locally like the nitrate of silver. Nothing is known of its effects on the human subject; but in administering it to animals, Orfila has found extensive inflammation, and even ulceration, of the mucous membrane of the stomach. (Toxicologie, ii. 30.) The metal is absorbed and carried into the tissues, but its poisonous action appears to be wholly independent of absorption.

**Preparations of Iron.**

Sulphate of Iron. Copperas. Green Vitriol.—This compound has been several times administered with malicious intention. One death from it took place in 1837-8. It cannot, however, be a very active preparation; for a girl who swallowed an ounce of it recovered, although she suffered for some hours from violent pain, vomiting, and purging. (Christison on Poisons, 506.)
Green vitriol or copperas is sometimes given as an abortive. A suspicious case is reported, in which a woman far advanced in pregnancy, but enjoying good health, was suddenly seized about midnight with vomiting and purging, and died in about fourteen hours. The body, which had been buried, was disinterred, and iron found in large quantity in the viscera. The symptoms are not always of this violent kind. In a case which occurred to M. Chevalier, a man gave a large dose of sulphate of iron to his wife. There was neither colic nor vomiting. The woman lost her appetite, but ultimately recovered. In another case reported by the same authority, a woman was tried and convicted of poisoning her husband with sulphate of iron: but in consequence of the great diversity of opinion among the scientific witnesses at the trial respecting the poisonous properties of this mineral salt, and the dose in which it would be likely to operate injuriously, the Court and Jury recommended that the sentence of death should not be carried into execution. (Ann. d’Hyg. 1851, i. p. 155.) The reader will find some additional remarks in reference to the action of the sulphate of iron on the body, by the late M. Orfila, in the same Journal, 1851, ii. 337.

Muriate of Iron. Tranquility of Sesquichloride of Iron.—This is an acid solution of peroxide of iron with alcohol, of a red colour, much used in medicine. Dr. Christison relates an instance in which a man by mistake swallowed an ounce and a half of this liquid: the symptoms were somewhat like those produced by muriatic acid. He at first rallied, but died in about five weeks. The stomach was found partially inflamed, and thickened towards the lesser end (the pylorus). This salt has been much used for criminal purposes in France. (See Medical Gazette, Vol. xlvi. p. 307: also Ann. d’Hyg. 1850, i. p. 180, 416; and, 1851, i. p. 155, ii. 337.) A case was reported to the Westminster Medical Society, in November 1842, in which a girl, aged fifteen, five months advanced in pregnancy, swallowed an ounce of the tincture of muriate of iron in four doses in one day, for the purpose of inducing abortion. Great irritation of the whole urinary system followed, but this was speedily removed, and she recovered. Another case of recovery from a large dose of this preparation has been reported by Mr. Amyot. A healthy married female swallowed, by mistake for an aperient draught, one ounce and a half of the tincture of muriate of iron. She immediately ejected a portion, and violent retching continued for some time. There was great swelling of the giottis, with cough, and difficulty of swallowing. These symptoms were followed by heat and dryness of the throat, with a pricking sensation along the course of the gullet and stomach; and in the afternoon a quantity of dark purulent blood was vomited. The motions were black, owing doubtless to the action of sulphur upon the metal. In about a month the patient was perfectly restored to health. (Provincial
Journal, April 7 and 21, 1847, 180.) Another case of recovery from a large dose has been reported by Sir James Murray. The patient, at 72, swallowed by mistake three ounces of the tincture in a concentrated state. The tongue soon became swollen; a ropy mucous flowed from the mouth and nose; there was croupy respiration, with a sense of impending suffocation. The pulse was feeble, the skin cold and clammy, and the face swollen and livid. A castor-oil mixture brought away inky evacuations, and the patient rapidly recovered. (Dub. Med. Press, Feb. 21, 1849.) This liquid has been used in large doses for the purposes of criminal abortion.

Chemical analysis.—The muriatic acid may be detected by nitrate of silver and nitric acid, while the peroxide of iron is immediately indicated by a precipitate of Prussian blue on adding a solution of Ferrocyanide of potassium.

Preparations of Bismuth.

Subnitrate of Bismuth. Pearl-white. Magistery of Bismuth.—This substance, in a dose of two drachms, caused the death of an adult in nine days. There was burning pain in the throat, with vomiting and purging, coldness of the surface, and spasms of the arms and legs,—also a strong metallic taste in the mouth. On inspection, the throat, larynx, and gullet were found inflamed; and there was inflammatory redness in the stomach and throughout the intestinal canal. (Sobernheim, 335.) In a case mentioned by Dr. Traill, a man took by mistake six drachms of the subnitrate, in divided doses, in three days. He suffered from vomiting and pain in the abdomen and throat, but finally recovered. (Outlines, 115.) These cases are sufficient to prove that a substance very slightly soluble in water may exert a powerfully poisonous action on the human system.

Preparations of Chrome.

Bichromate of Potash.—Well-observed instances of poisoning by this compound, which is now extensively used in the arts, are rare; and therefore, the details of the following case, communicated to the Medical Gazette (xxxiii. 734) by Mr. Wilson of Leeds, are of practical interest. A man, aged sixty-four, was found dead in his bed twelve hours after he had gone to rest: he had been heard to snore loudly during the night, but this had occasioned no alarm to his relatives. When discovered, he was lying on his left side, his lower limbs being a little drawn up to his body; his countenance was pale, placid, and composed; eyes and mouth closed; pupils dilated; no discharge from any of the outlets of the body; no marks of vomiting or purging, nor any stain upon his hands or person, or upon the bed linen or furniture. The surface was moderately
warm. Some dye-stuff, in the form of a black powder was found in his pocket. On inspection, the brain and its membranes were healthy and natural; there was neither congestion nor effusion in any part. The thoracic viscera were equally healthy, as well as those of the abdomen, with the exception of the liver, which contained several hydatids. A pint of a turbid inky-looking fluid was found in the stomach. The mucous membrane was red and very vascular, particularly at the union of the greater end with the gullet; this was ascribed to the known intemperate habits of the deceased. In the absence of any obvious cause for death, poison was suspected; and on analysing the contents of the stomach they were found to contain bichromate of potash. The dye-powder taken from the man's pocket consisted of this salt mixed with cream of tartar and sand. It is remarkable that in this case there was neither vomiting nor purging. The salt does not appear to have operated so much by its irritant properties as by its indirect effects on the nervous system. This, however, is by no means an unusual occurrence, even with irritants far more powerful than the bichromate of potash. A case has been communicated to me by Mr. Bishop, of Kirkstall, in which a boy recovered from the effects of a dose of this salt only after the lapse of four months. The first symptoms were pain, vomiting, dilated and fixed pupils, cramps in the legs, and insensitivity. His recovery was due to early and active treatment. A report of this case will be found in Guy's Hosp. Reports, Oct. 1850, p. 214.

There can be no doubt that bichromate of potash is an active poison. Mr. West has published a case from which it appears that a medical man, who had inadvertently tasted a solution of it, suffered from severe symptoms, resembling those of Asiatic cholera. (Provincial Journal, Dec. 24, 1851, p. 700.)
GENERAL REMARKS.—MODE OF ACTION OF VEGETABLE IRRITANTS. ALOES. COLOCYNTH. GAMBOGE. JALAP. SCAMMONY. SAVIN. CROTON OIL. CASTOR SEEDS. OIL OF TURPENTINE. OIL OF TAR. MOULDY BREAD. DARNEL. ERGOT OF RYE. CAROB OR LOCUST BEAN.

General Remarks.—The poisonous substances of an irritant nature which belong to the vegetable kingdom are very numerous as a class; but it will here be necessary to notice only those which have either caused death, or have given rise to accidental poisoning.

ALOES. COLOCYNTH. GAMBOGE. JALAP. SCAMMONY.

These different substances, which are used in small doses as medicines, are liable, when taken in large quantities, to excite vomiting, purging, and other symptoms of irritation. Colocynth has occasioned death in several instances: in one case a teaspoonful and a half of colocynth powder destroyed life; and one drachm of gamboge, a medicine much used by quacks, has proved fatal to man. (Traill's Outlines, 150.) Aloe and colocynth mixed are said to be the basis of a certain quack medicine sold under the name of Morison's Pills. These have proved fatal in many instances from the exhaustion produced by excessive purging, owing to the large quantity of these pills taken in frequently repeated doses. Our knowledge of the symptoms and appearances produced by these irritants, is, indeed, chiefly derived from the cases which have proved fatal under this pernicious treatment. In the seventeenth volume of the Medical Gazette will be found four cases of this description. The most prominent symptom is excessive purging, with the discharge of large quantities of mucus; the individual becomes emaciated, and slowly sinks. In some instances the symptoms are those of inflammation and ulceration of the bowels. In 1836, a man was convicted of having caused the death of a person by the administration of these pills; in this instance the death of the deceased
was clearly due to the medicine; and on inspection, the stomach
was found inflamed and ulcerated; the mucous membrane of the
small intestines was inflamed and softened, and there was the ap-
pearance of effused lymph upon it. An ingenious attempt was
made in the defence to draw from the medical witness a state-
ment that the good effects of some medicines invariably increased
in proportion to the quantity taken. This anti-homeopathic
proposition was, however, very properly rejected. The same
remarks apply to Holloway’s pills, although these are of a more
innocent description. The principal ingredient in them is aloes.
In all cases it must be remembered that these drastic purgatives
may cause serious symptoms or even death when administered to
infants, or to persons debilitated by age or disease; and it is not
necessary that the dose should be very large for fatal effects to
follow. The question here will be, whether the medicine caused
death, or whether it simply accelerated it: although in a legal
view, that which accelerates, causes.

Hierapicra (Holy bitter) is a popular aloeotic compound, and
one death is recorded to have been produced by it in 1837–8.
There is reason to believe that it is occasionally used for the
purpose of procuring criminal abortion. A man was tried and
convicted of this offence at the Aylesbury Lent Assizes, 1857
(Reg. v. White), and the noxious properties of this compound
then became a subject of inquiry. The dose, and the condition
of the woman to whom it is administered, will of course affect
the answer to this question. At the trial above-mentioned, it
was properly considered to be a noxious substance within the
meaning of the statute. The fact that under the name of
Pulvis Aloes cum Canella, it was formerly admitted into the
British Pharmacopoeias, cannot justify the mischievous uses to
which it may be put.

Hierapicra is a snuff-coloured powder, of an intensely bitter
taste. It consists of four parts by weight of aloes, and one part
by weight of powdered Canella bark. The proper medicinal dose
was formerly fixed at from five to fifteen grains. Its injurious
effects on pregnant females are chiefly due to the aloes. This
specially affects the rectum, and by contiguity, under violent
irritation or purging, may affect the uterus. From the taste
and colour which it imparts to liquids, it is not probable that
it could be taken by a female unknowingly.

In another instance death was caused by aloes taken in nitric
acid, in which case the mineral acid was most probably the de-
structive agent. A singular case occurred in Germany a few
years since, wherein a medico-legal question was raised respecting
the poisonous properties of Aloes. A woman, aged forty-three,
not labouring under any apparent disease, swallowed two
drachms of powdered aloes in coffee. Violent purging superv-
ened, and she died the following morning, twelve hours after
having taken the medicine. On inspection, the stomach was found partially, and the small intestines extensively, inflamed. There were no other particular appearances to account for death, and this was referred to the effect of the aloees.

**Savin. (Juniperus Sabina.)**

This is a well-known plant, the leaves or tops of which contain an irritant poison in the form of an acrid volatile oil of a remarkable odour. They exert an irritant action, both in the state of infusion and powder. They yield by distillation a light yellow oil, on which the irritant properties of the plant depend. The powder is sometimes used in medicine in a dose of from five to twenty grains. Savin is not often taken as a poison for the specific purpose of destroying life; but this is occasionally an indirect result of its use, as a popular means of procuring abortion. In this manner it appears to have proved fatal in one case in 1837–8. From the little that is known of its effects, it acts by producing violent pain in the abdomen, vomiting, and strangury. After death, the gullet, stomach and intestines, with the kidneys, have been found either much inflamed or congested. It has no action as an abortive, except like other irritants, by causing a violent shock to the system, under which the uterus may expel its contents. Such a result can never be obtained without placing in jeopardy the life of a woman; and when abortion follows, she generally falls a victim. On the other hand, the female may be killed by the poison without abortion ensuing. In May, 1845, I met with a case in which death had been caused by savin-powder,—abortion having first taken place. Eight ounces of green liquid were found in the stomach, which, with the gullet and the small intestines, was highly inflamed. The poison was easily identified by placing some of the minute portions of the leaves found in the stomach, under a microscope. (Med. Gaz. xxxvi. 646.)

**Croton Oil.**

This is an oil extracted from the seeds of the Croton tiglium. It is a powerful drastic purgative, producing in a large dose severe purging, collapse, and death. A case occurred in Paris in 1839, in which a man swallowed by mistake two drachms and a half of croton oil. In three-quarters of an hour the surface was cold and clammy, the pulse imperceptible, respiration difficult, and the extremities and face were as blue as in the collapsed stage of cholera. In an hour and a half purging set in; the stools were passed involuntarily, and the abdomen was very sensitive to the touch. The patient complained of a burning pain in the course of the gullet. He died in four hours after swallowing the
poison. There was no marked change in the mucous membrane of the stomach.

In June, 1850, I was consulted in a case in which it was supposed that this liquid had been employed for the purpose of destroying life; and, although arsenic was found in the stomach, it became a question to determine what was the fatal dose of this oil. In this instance, sixty drops had been sold, mixed with two ounces of linseed oil. This is considered a proper dose for cattle. In man, a dose of from fifteen to twenty drops of the pure oil might give rise to excessive purging, and thus cause death by exhaustion. The cases recorded of its fatal operation are very few, and do not enable us to solve this question from observed facts. According to Landeberg, as quoted by Christison, (Dispensatory, p. 382), thirty drops of the oil have killed a dog, and Dr. Christison states that he has known four grains of the oil to produce an alarming degree of purging. It is frequently adulterated with castor-oil and other substances, and these adulterations must of course influence the dose required to act fatally.

In a recent volume of the Medical Gazette, there is a report of a case in which a woman died from the effects of an embrocation, containing croton oil—with other drugs. A teaspoonful was incautiously given to her: she immediately complained of a hot burning sensation in her throat. She was an aged person, and died in convulsions in three days (Med. Gaz. Vol. xliii. page 41).

CASTOR SEEDS.

Of castor oil itself nothing need be said. It is not commonly known that the seeds from which this oil is extracted, contain in the embryo a very active poison, and that a few of them are sufficient to produce violent purging and death. The following is an instance of poisoning by these seeds,—the only one with which I have met. The deceased, aged eighteen, was the sister of a gentleman who was at the time attending my lectures at Guy's Hospital.

The deceased, it appears, ate about twenty castor-oil seeds; one of her sisters ate four or five, and another, two. This was on a Wednesday evening. In the night they were all taken ill. About five hours after the seeds were eaten, the deceased felt faint and sick; vomiting and purging came on, and continued through the night. On the following morning she appeared like one affected with malignant cholera. The skin was cold and dark-coloured, the features contracted, and the breath cold; the pulse was small and wiry; there was restlessness, thirst, pain in the abdomen, and she lay in a sort of drowsy, half-conscious state. Whatever liquid was taken was immediately rejected, and the matters passed by stool consisted chiefly of a serous fluid with blood. She died in five days without rallying; the two
other sisters recovered. On inspection, a very large portion of the mucous membrane of the stomach was found abraded and softened in the course of the great curvature. There was general vascularity of the organ, and the abraded portion presented the appearance of a granulating surface of a pale rose-colour; it was covered by a considerable quantity of slimy mucus. The small intestines were inflamed, and the inner surface of them was abraded. The effects produced on the sisters who recovered, bear out the statement of Dr. Christison, that two or three of the seeds will operate as a violent cathartic.

**The Elder. (Sambucus nigra.)**

Dr. Christison states that the leaves and flowers of the common elder act as an irritant poison, having caused in a boy severe inflammation of the bowels, which lasted for eight days. (Ed. Med. and Surg. Jour. xxxiii. 73.) The berries of this tree do not appear to possess, in the ripe state, any noxious properties. The following case of poisoning by the expressed juice of the roots is reported in the Med. Gaz. xxxv. 96.

A weakly woman, fifty four years of age, who had been sick all day, and thrown up a quantity of greenish matter, which she regarded as bile, was persuaded by her husband to take two tablespoonsfuls of the juice of the fresh elder root, which he himself had dug up, shaved down, and pressed. The woman soon after complained of severe pain in the abdomen. She was ordered some infusion of senna, but did not take it, as the bowels began almost immediately to act copiously. Next day the symptoms were those of enteritis, which proved fatal.

**Oil of Turpentine.**

The few cases in which this liquid has produced any noxious symptoms have occurred among children. From these it appears to have rather the effects of a narcotic (narcotic) than an irritant poison. In a dose of three drachms, it has produced intoxication. A dose of a tablespoonful caused in a child, aged eighteen months, symptoms bearing a strong resemblance to those occasioned by an overdose of opium, although they were not so rapidly manifested. (See case by Mr. Johnson, Med. Times, Oct. 11, 1851, page 380.) In three hours there was complete insensibility,—stertorous breathing, strongly contracted pupils, rapid and weak pulse,—coldness of surface, paleness of the countenance, — general relaxation of the muscles, with occasional convulsive movements. In no instance yet recorded has this oil caused death. A case of recovery in an infant that had swallowed four ounces, is recorded in another work (On Poisons).

A case in which this liquid was criminally administered to an infant, was the subject of a trial at the Central Criminal Court, December 1856 (Reg. v. Rodanbosh): it did not destroy
life, but the child suffered for some time from the effects. The
defence was, that the oil of turpentine was poured down the
child's throat by the mother with a view to cure it of a cough!
She was acquitted.

OIL OF TAR.

This is a powerful vegetable irritant. In 1832, about ten
drachms of it caused the death of a gentleman, to whom it had
been sent by mistake for a black draught. The party who sent
it was tried for manslaughter, but acquitted. The irritant
properties are owing to cresote and other compounds.

MOULDY BREAD.

There is a common article of food, namely bread, upon the oc-
casionally noxious effects of which some observations have been
made by toxicologists. (In the Annales d'Hygiène, 1843, pp. 35
and 347, will be found communications on this subject from MM.
Guérard, Chevallier, and Gaultier de Claubry; also in the same
journal, 1852, i. p. 350.) The changes which take place in the
decomposition of flour and bread, and the production of various
kinds of mouldiness, are here investigated, together with the effects
of such bread upon the animal system. It would appear that in
some parts of France the peasantry manifest no repugnance to
the eating of mouldy bread; and that in many instances the
practice appears to be attended with no ill effects. The nature
of the mould produced, however, is subject to great variation,
and it is not improbable, as M. Chevallier suggests, that in some
cases a poisonous principle is actually developed. In two in-
stances of children, who had partaken of mouldy rye-bread,
symptoms resembling those of irritant poisoning supervened.
The countenance was red and swollen; the tongue dry; the pulse
quick; there were violent colics, with pain in the head, and in-
tense thirst. Vomiting and purging supervened with a state of
collapse, but the children eventually recovered. These symptoms
were ascribed to the production of "mucor mucido" in the bread.
In 1829, alarming effects having followed from the use of a
certain kind of bread in Paris, M. Barruel was called upon to
determine whether any irritant poison had or had not become
accidentally intermixed with it. The bread was simply in a
mouldy state; there was no trace of poison. It is unnecessary
to enter further into this subject; the facts adduced, together
with experiments performed on animals, show that bread, in a
state of mouldiness or decay, may not only produce symptoms of
poisoning, but actually cause death; and as it is impossible to
distinguish the noxious from the innoxious kind of mould, the
use of all bread in such a condition should be avoided.

Even fresh bread may occasionally seriously affect the body.
The brown bread of London has been known to produce giddiness,
lethargy, and other unpleasant symptoms, indicative of an affection of the brain and nervous system. This has been ascribed, with some probability, to the presence of Darnel seeds in the corn.

DARNEL. (LOLIIUM TEMULENTUM.)

In January 1854, Dr. Kingsley, of Roscrea, furnished me with the particulars of some cases in which several families (including about thirty persons) suffered severely from the effects of bread containing, by accidental admixture, the flour of Darnel seeds. The persons who partook of this bread staggered about as if intoxicated; there was giddiness, with violent tremors of the arms and legs, similar to those observed in delirium tremens, but of much greater intensity (the patients requesting those about them to hold them, and experiencing great comfort for this assistance being given to them); greatly impaired vision, everything appearing quite green to the sufferer; coldness of the skin, particularly of the hands and feet; great prostration of strength, and in several cases vomiting. Under the free use of stimulants and castor oil the whole of the patients were convalescent the following day, but much debilitated from the effects of the poison. In one instance in which Darnel seeds were mixed in the proportion of one-tenth part with rye, the persons partaking of the bread suffered from giddiness, headache, nausea, vomiting, deafness, and cramps. (Medical Gazette, xlv. 872; Ann. d’Hyg. 1853, ii. p. 147.) Among the symptoms in other cases there has been noticed a sense of burning in the mouth and throat, with confusion in the head, trembling, and a small irregular pulse. (See Ed. Monthly Jour., Aug. 1850, p. 180.) When these symptoms attack simultaneously many persons who partake of the same bread there is strong ground for suspicion.

Rye-bread is not much used in this country, but the accidental presence of Ergot might, in some cases, account for the symptoms of poisoning which have been observed. (See Ann. d’Hyg. 1834, ii. 179; 1835, ii. 240; 1843, i. 41, 347; Henke, Zeitschrift der S. A. 1842. ii, 185; 1844, i. 286, ii. 215.)

CAROB OR LOCUST BEAN.

The locust beans or locust nuts have been much used in England for the fattening of cattle; but in a few cases in which they have been eaten by children, they are supposed to have occasioned violent irritation; and in one case (March 1857), a boy, aged ten years, died in about sixteen hours, apparently from their poisonous action on the body. The chief symptoms during life were pain in the head, vomiting, and purging, with clenching of the hands, and a spasmodic action of the muscles of the face. On inspection the stomach and intestines were found much inflamed. The viscera were carefully examined by Mr. Watson
of Bolton, but no poison could be detected. Another fatal case, as it was alleged from eating locust nuts, occurred subsequently in London, and was the subject of an inquest before Mr. Wakley. The facts at present scarcely admit of an explanation. The nuts contain no substance injurious to animals, and as it is alleged that many human beings have eaten them with impunity, the effects produced in the above cases may have been dependent on idiosyncrasy in those who have suffered (ante, page 7; see also On Poisons).

Other vegetable irritants might be enumerated, but these are the principal which have given rise to medico-legal inquiries. The treatment of such cases must depend on the nature of the symptoms; the main object should always be to remove the poison either from the stomach or bowels, by mild emetics or purgatives (castor-oil), with as little delay as possible. The nature of the poison is commonly apparent from the circumstances; for these cases, if we except poisoning by Savin, which is sometimes criminally administered, are generally the result of accident. These vegetable poisons are beyond the reach of chemical processes: they are only to be recognised either by their physical properties, or by the botanical characters of the berries, seeds, or leaves.
ANIMAL IRRITANTS.

CHEESE — SAUSAGES — DISEASED FLESH OF ANIMALS.

CANTHARIDES. (SPANISH FLY.)

Symptoms and effects. — This poison has been frequently administered, either in the state of powder or tincture, for the purpose of exciting aphrodisiac propensities, or of procuring abortion. When taken in powder, in the dose of one or two drachms, it gives rise to the following symptoms: — a burning sensation in the throat, with great difficulty of swallowing — violent pain in the abdomen, with nausea, and vomiting of bloody mucus: — there is also great thirst and dryness of the fauces, but in a few cases observed by Mr. Maxwell, salivation was a prominent symptom. As the case proceeds, pain is commonly experienced in the loins, and there is incessant desire to void urine, but only a small quantity of blood or bloody urine is passed at each effort. The abdominal pain becomes of the most violent griping kind. Purging supervenes, but this is not always observed: — the matters discharged from the bowels are mixed with blood and mucus, and there is often tenesmus (straining). In these, as well as in the vomited liquids, shining green particles may be commonly seen on examination, whereby the nature of the poison taken is at once indicated. After a time, there is severe priapism, and the genital organs are swollen and inflamed both in the male and female. In one instance, observed by Dr. Pereira, abortion was induced, probably owing to excitements of the uterus, from the severe affection of the bladder: for there is no proof that this substance acts directly on the uterus to induce abortion. With respect to the aphrodisiac propensities caused by cantharides, these can seldom be excited in either sex, except when the substance is administered in a dose which would seriously endanger life. When the case proves fatal, death is usually preceded by faintness, giddiness, and convulsions.
SYMPTOMS AND APPEARANCES.

The tincture of cantharides produces similar symptoms: — they are, however, more speedily induced, and the burning sensation and constriction of the throat and stomach are more strongly marked: this symptom is often so severe as to render it impossible for the individual to swallow; and the act of swallowing gives rise to excruciating pain in the throat and abdomen.

Appearances. — In one well-marked case of poisoning by this substance, the whole of the alimentary canal, from the mouth downwards, was in a state of inflammation, as well as the ureters, kidneys, and internal organs of generation. The mouth and tongue seemed to be deprived of their mucous membrane. In another instance, in which an ounce of the tincture was swallowed, and death did not occur for fourteen days, the mucous membrane of the stomach was not inflamed; but it was pulpy, and easily detached. The kidneys were, however, inflamed. The brain has been found congested, and ulceration of the bladder is said to have been met with. There are few fatal cases reported, in which the appearances have been accurately noted; indeed, the greater number of those who have taken this poison have recovered. In a case which occurred to Mr. Saunders, death took place in about twenty-four hours. The deceased must have taken the greater part of half an ounce of cantharides in powder. The symptoms were such as have been above described. On inspection, the vessels of the brain were filled with dark-coloured blood, and the ventricles were distended with serum. Both lungs were highly engorged with dark-coloured blood. The gullet was partially inflamed, and there were patches of inflammation on the mucous coat of the stomach, which had become detached in several places. The same inflammatory appearance existed in the small intestines, in the folds of which the powder of cantharides was abundantly seen. The vessels were distended, and the liver was engorged with dark blood. The gall-bladder was much distended with bile, and none of this secretion appeared to have passed into the bowels. The spleen and kidneys were highly congested; the ureters were inflamed; the bladder contracted and empty, and its internal surface pale. The glittering of the particles of cantharides in the viscera during the inspection by candlelight was very remarkable. (Medical Times, Feb. 3, 1849, page 287.) Cantharides have no local action of a chemical nature. The poison is a pure irritant, and the effects observed are entirely due to irritation and inflammation.

Fatal dose. — The quantity of this poison required to produce serious effects, or to destroy life, has been a frequent subject of medico-legal inquiry. Dr. Thomson represents the medicinal dose of the powder to be from one to three grains. On a late criminal investigation one medical witness stated, that one grain was the maximum dose, but this is an under-statement; according
to Thomson it is three grains. The dose of the London Pharmacopeial tincture is from ten minims gradually increased to one fluid-drachm,—of the powder, from one to two grains. (Pereira, Mat. Med. Part ii. Vol. ii. 754.) Doses above this, whether of the powder or the tincture, are likely to be injurious, and to give rise to symptoms of poisoning. On a trial which took place at Aberdeen, in 1825, it appeared that a drachm of the powder had been administered: severe symptoms followed, but the person recovered. Dr. Dyce, the medical witness, said he had given ten grains of the powder as a medicinal dose. In three cases, observed by Mr. Maxwell, a drachm of the powder mixed with six ounces of rum was taken by each person: they were robust, healthy negroes,—they suffered severely, but recovered in about ten days: in these cases, irritation of the urinary organs did not appear until after the men had been bled. The smallest quantity of powder which has been known to destroy life, was in the case of a young female, quoted by Orfila,—the quantity taken was estimated at twenty-four grains in two doses. She died in four days; but as abortion preceded death, it is difficult to say how far this may have been concerned in accelerating that event. Her intellect was clear until the last. In one instance a man recovered after having taken twenty grains of the powder (Ed. Med. and Surg. Journ. Oct. 1844); and in another, after having taken two drachms (Med. Gaz. xxii. 873).

An ounce of the tincture has been known to destroy life. It was taken by a boy, aged seventeen, and he died in fourteen days. This, I believe, is the smallest dose of the tincture which has killed. Dr. Pereira met with a case in which one ounce destroyed life (Mat. Med. Vol. ii. Pt. ii. p. 750.). In the following instance a similar dose produced severe symptoms. A woman, aged twenty-nine, swallowed an ounce of tincture of cantharides. Some time afterwards, there was severe pain in the abdomen, increased by pressure: it was swollen and tympanitic. She passed in the night a pint and a half of urine unmixed with blood. In two days, the pulse became feeble and scarcely perceptible;—there was delirium, with severe pain in the region of the kidneys and bladder: the urine was continually drawn off by a catheter. It was more than a fortnight before she was convalescent. (Med. Gaz. xxix. 63.) Four drachms and even six drachms have been taken; and although the usual symptoms followed, the parties did well. The last case was the subject of a trial at the Central Criminal Court, in September, 1836. Six drachms of the tincture were administered to a girl, aged seventeen: the medical witness was required to say whether half an ounce was sufficient to kill, as also what proportion of cantharides was contained in an ounce of the tincture; he said, five grains. One ounce of the tincture (P.L.) is equivalent to six grains of the powder; but considering that the principle cantharidine is the substance
CANTHARIDES. CHEMICAL ANALYSIS. 155

on which the poisonous properties depend, it is very likely that
the tincture varies in strength according to its mode of pre-
paration. A case is quoted by Pereira, from Dr. Hosack (Mat.
Med. Vol. ii. Pt. ii. p. 750.), in which it is said six ounces of the tinc-
ture were taken by a man without causing dangerous symptoms!
This must have been an extraordinarily weak preparation; and
probably the insects from which the tincture was made contained
little or no cantharidine. The same writer mentions a case
within his own knowledge, in which one ounce of the tincture
caused serious symptoms.

Chemical analysis.—Ofilia has applied reagents to detect can-
tharidine in the tincture; but without success. It has been
recommended to digest the suspected solid or the liquid contents
of the stomach evaporated to an extract, in successive quantities
of ether,—to concentrate these ethereal solutions by slow eva-
poration, and then observe whether the concentrated liquid ap-
plied to the skin of the lips produces vesication or not: the me-
dical jurist being expected in such cases to make himself the
subject of experiment. In this way Barruel discovered can-
tharides in some chocolate. (Ann. d’Hyg. 1835, i. 455.) In
an elaborate essay on this subject (Ann. d’Hyg. Oct. 1842),
M. Poumet recommends that the suspected liquids, mixed with
alcohol, should be spread on sheets of glass, and allowed to
evaporate spontaneously to dryness. The shining scales will
then be seen, on examining, by reflected light, either one or both
surfaces of the glass. This process answers very well for the
detection of the powder.

The evidence of the presence of cantharides, or of their having
been taken, is necessary to support a criminal charge; for, how-
ever unambiguous the symptoms produced by this poison may
appear to be in its peculiar effects on the generative and urinary
apparatus, the medical jurist should be aware that similar symp-
toms may proceed from disease. An important case of this kind
has been reported by Dr. Hastings. (Med. Gaz. xii. 431.) A
young lady was suddenly seized with vomiting, thirst, pain in
the loins, strangury, and considerable discharge of blood from the
urethra: the generative organs were swollen and painful. She
died in four days. She was governess in a family, and there was
some suspicion that she had been poisoned by cantharides. The
stomach and the kidneys were found inflamed, and the bladder
also; this contained about two ounces of blood. There was no
trace of poison; and indeed, it was pretty certain, from the
general evidence, that none could have been taken.

POISONOUS FOOD.

Certain kinds of animal food are found to produce, occasion-
ally, symptoms resembling those of irritant poisoning. In some
cases this poisonous effect appears to be due to idiosyncrasy; for only one person out of several may be affected. These cases are of some importance to the medical jurist, since they are very likely to give rise to unfounded charges of criminal poisoning. In the absence of any demonstrable poison, we must test the question of idiosyncrasy by observing whether more than one person is affected, and whether the same kind of food, given to animals, produces symptoms of poisoning. If, with this latter condition, several persons be affected simultaneously, we cannot refer the effects to idiosyncrasy; they are most probably due to the presence of an animal poison. Among the articles of food which have given rise to symptoms of poisoning, may be mentioned,—

Poisonous Fish. Mussels. Salmon.—Of all the varieties of shell-fish, none have so frequently given rise to accidents as the common mussel. The symptoms which it produces, are uneasiness and sense of weight in the stomach, sensation of numbness in the extremities, heat and constriction in the mouth and throat; thirst, rigors, difficulty in breathing, cramps in the legs, swelling and inflammation of the eyelids, with a profuse secretion of tears, and heat and itching of the skin, followed by an eruption resembling nettle-rash. The symptoms are sometimes accompanied by vomiting, colic, and purging. They may occur within ten minutes or a quarter of an hour; but their appearance has been delayed for twenty-four hours. There is generally great debility. These symptoms have proceeded from the eating of not more than ten or twelve mussels. Two cases, reported by Christison, proved fatal, the one in three, and the other in about seven hours. In general, however, especially when there is free vomiting, the patients recover. In the inspection of the two above-named fatal cases, no appearance was found to account for death. The treatment consists in the free exhibition of emetics. A case in which two mussels produced in a boy aged ten, very alarming symptoms, followed by an eruption resembling scarlatina and nettle-rash, will be found elsewhere reported (Guy's Hosp. Reports, Oct. 1850, 213).

The poisonous action of mussels can neither be referred to putrefaction nor disease; nor in all cases to idiosyncrasy, since sometimes those mussels only have been poisonous which have been taken from a particular spot; all persons who partook of them suffered, and a dog was killed to which some of them were given. From a case which occurred to M. Bouchardat, it would appear that copper is sometimes present, and may be the cause of the poisonous effects. Two women were poisoned by mussels, and he found on analysis sufficient copper in the fish to account for the symptoms of irritation from which they suffered. (Ann. d'Hyg. 1837, i. 358.) Copper is not, however, present in all cases, and it is therefore probable that there is in
somes, if not in all instances, an animal poison present in the fish. (See Ann. d'Hyg. 1851, i. 387, ii. 108.) Oysters and Periwinkles have occasionally given rise to similar symptoms. Salmon, sold in the state of pickled salmon, or even Herrings salted, may also act as irritants: this may be due to the fish being partially decayed before it is used. In 1834, two persons at Maidstone lost their lives from eating salmon of this description.

[For some remarks by Dr. Hamilton on the poisonous properties of fish see the Pharmaceutical Journal, Jan. 1853, 244.]

Cheese. Sausages.—These articles of food have frequently given rise to symptoms of poisoning in Germany, but there is, I believe, no instance of their having proved fatal in England. The symptoms produced by cheese have been those of irritant poisoning. The nature of the poison is unknown. In some cases the irritant property is undoubtedly due to a putrefied state of the curd. Again, it has been supposed that the poison is occasionally derived from certain vegetables on which the cows feed. The symptoms caused by the sausage-poison are very slow in appearing, — sometimes two, three, or four days elapsed before they manifest themselves; they partake of the narcotic-irritant character. This poison is of a very formidable kind. In the Medical Gazette for Nov. 1842, there is an account of the cases of three persons, who had died from the effects of liver-sausages, which had been made from an apparently healthy pig, slaughtered only a week before. The inspection threw no light on the cause of death. The poisonous effect is supposed to depend on a partial decomposition of the fatty parts of the sausages. It is said, that when extremely putrefied, they possess no poisonous properties!

Pork. Bacon.—These common articles of food occasionally give rise to symptoms so closely resembling those of irritant poisoning, as to be easily mistaken for them. In some cases, the effect appears to be due to idiosyncrasy; but in others it can only be explained by supposing the food to have a directly poisonous action. The noxious effects of pork have been particularly shown by the cases published by the late Dr. MacDivitt. (Ed. Med. and Surg. Jour. Oct. 1836.)

There is no doubt that epizootic disease may be a frequent cause of rendering animal food poisonous. Partial decay may also render unwholesome and injurious the flesh of the most healthy animal. What the nature of the poison is which is thus produced, has not yet been determined. Liebig imagines that it is owing to the production of a fermenting principle, and that it operates fatally by producing a kind of fermentation in the animal body. It has been said that the symptoms of irritant poisoning produced by animal food seldom appear until five or six hours after the meal. This may be generally true, but in certain instances it has undoubtedly happened that the symp-
toms came on in from a quarter to half an hour after the noxious food was taken.

Much of the game and butcher's meat sold to the poor in this metropolis is in a state of decay, and quite unfit for human food. In January 1851, the family of a surgeon near London were all affected with symptoms resembling irritant poisoning, after having partaken of a hare which had been stewed in a clean earthen vessel. The surgeon informed me that on the second day, his wife was seized with vomiting and purging, giddiness, heat in the throat, and general numbness, with semi-inflamed eyes. Other members of the family vomited, and in the course of a few days the symptoms disappeared. I examined the vomited matter, and found it to consist of portions of the hare partially digested, but in a state of putrefaction, so that there was abundant evidence of sulphuretted hydrogen in the liquid. There was no mineral poison of any kind, although the symptoms, it will be observed, were rather like those occasioned by arsenic. It had been remarked by the family, that a silver spoon, which had been used in serving out this unwholesome food, was turned of a brown colour, no doubt from the chemical action of sulphuretted hydrogen; and this may be taken as a good domestic test of the putrefied condition of such food. Nature generally applies an appropriate remedy, in the fact that the food itself produces copious vomiting and purging.

Cases of this kind must be distinguished from those in which poisoned game is sold to the public. The game may be quite free from putrefaction, but noxious from the poisoned grain which may have caused death. It is a very common practice to steep grain in a solution of arsenic, previous to sowing, and pheasants, partridges, and other birds may be accidentally destroyed by eating the grain. In some instances, grouse and other game are maliciously destroyed by corn saturated in arsenic being laid in the localities where the birds abound. There is no law to prevent the sale of poisoned game by poulterers, and there is no precaution which can be taken by the purchasers, except by observing whether the birds have or have not been shot. (See on this subject, On Poisons; also a letter by Dr. Fuller, Med. Gaz. xlii. 1036.)

Opium.

Symptoms. — The symptoms which manifest themselves when
a large dose of opium or its tincture has been taken, are in
general of a uniform character. They consist in giddiness, drow-
siness, a strong tendency to sleep, stupor, succeeded by perfect
insensibility, the person lying motionless, with the eyes closed
as if in a sound sleep. In this state he may be easily roused by
a loud noise, and made to answer a question: but he speedily
relapses into stupor. In a later stage, when coma has super-
vened with stertorous breathing, it will be difficult, if not im-
possible, to rouse him. The pulse is at first small, quick, and
irregular, the respiration hurried, and the skin warm and bathed
in perspiration — sometimes livid: but when the individual be-
comes comatose, the breathing is slow and stertorous: the pulse
slow and full. The skin is occasionally cold and pallid. The
pupils are sometimes contracted, at others dilated. From
cases which I have been able to collect, contraction of the
pupils is much more frequent than dilatation. In a case referred
to me in 1846, one pupil was contracted and the other dilated.
They are commonly insensible to light. The expression of the
countenance is placid, pale, and ghastly: the eyes are heavy,
and the lips are livid. Sometimes there is vomiting, or even purging; and if vomiting takes place freely before stupor sets in, there is great hope of recovery. This symptom is chiefly observed when a large dose of opium has been taken; and it may then be, perhaps, ascribed to the mechanical effect of the poison on the stomach. The odour of opium is occasionally perceptible in the breath. Nausea and vomiting, with headache, loss of appetite and lassitude, often follow on recovery. The muscles of the limbs feel flabby and relaxed, the lower jaw drops, the pulse is feeble and imperceptible, the sphincters are in a state of relaxation, the temperature of the body is low, there is a loud mucous rattle in breathing, and convulsions are sometimes observed before death; these are more commonly met with in children than in adults. One of the marked effects of this poison is to suspend all the secretions except that of the skin. During the lethargic state, the skin, although cold, is often copiously bathed in perspiration. It is a question yet to be determined, whether this may not be a medium by which the poison is principally eliminated.

These symptoms usually commence in from half an hour to an hour after the poison has been swallowed. Sometimes they come on in a few minutes, especially in children; and at others their appearance is protracted for a long period. In a case reported by Dr. Skae, the individual was found totally insensible in fifteen minutes. As we might expect, from the facts connected with the absorption of poisons, when the drug is taken in the solid state, the symptoms are commonly more slow in appearing, than when it is dissolved in water or alcohol.

Appearances. — In a case which proved fatal in fifteen hours, the vessels of the head were found unusually turgid throughout. On the surface of the anterior part of the left hemisphere there was an ecchymosis, apparently produced by the effusion of a few drops of blood. There were numerous bloody points on the cut surface of the brain; there was no serum collected in the ventricles. The stomach was quite healthy. Fluidity of the blood is mentioned as a common appearance in cases of poisoning by opium. There is also engorgement of the lungs; most frequently observed, according to Dr. Christison, in those cases which have been preceded by convulsions. (Op. cit. 732.) Among the external appearances there is often great lividity of the skin. This may be taken as a general statement of the appearances in poisoning by opium. Extravasation of blood on the brain is rarely seen; serous effusion in the ventricles, or between the membranes, is sometimes met with. The stomach is so seldom found otherwise than in a healthy state, that the inflammatory redness said to have been occasionally met with, may be regarded as probably due to accidental causes. When tincture of opium has been taken and retained on the stomach,
increased redness of the mucous membrane may occasionally be produced by the alcohol alone.

In a case of poisoning by a large dose of tincture of opium, Dr. Sharkey found the following appearances twelve hours after death:—the body warm and rigid; the stomach healthy, containing a quantity of a gruel-like fluid, without any smell of opium. The intestinal canal and all the other viscera were healthy. The veins of the scalp, as well as of the dura mater and sinuses, were gorged with blood; but there was no effusion in any part of the brain. The contents of the stomach yielded no trace of morphia or meconic acid, but there was no doubt that death had been caused by opium, taken the previous night. (Med. Gaz. xxxvii. 235.)

This description of the appearances refers to the action of large doses on adults. In a case which I had to investigate a few years since, a child aged fourteen months was killed in eighteen hours, from the effects of a dose of infusion of opium, equivalent to from three to five grains of the powder. The inspection of the body was made about twenty-four hours after death. It was not emaciated; and, externally, there were no particular appearances, excepting a few livid spots on the skin of the abdomen, back, and genitals, as also on the upper part of the thighs, sides, and back of the neck. The eyelids were open; the eyes sunk in the orbits, and their transparency gone: the child, it seems, had died with its eyes prominent and open. The pupils appeared contracted, but the condition of the iris was not particularly noticed during life. The viscera of the chest were perfectly healthy; there was no mark of effusion, or of any organic disease. The right cavities of the heart were congested, and the lining membrane of this organ was observed to be somewhat opalescent. The viscera of the abdomen were also healthy, except the kidneys, the structure of which had undergone a slight change from disease. The stomach was perfectly healthy; the mucous membrane was raised into numerous folds, but there was no trace of inflammation or disease in any part. The cavity of the organ contained about a teaspoonful of a white viscid liquid, apparently consisting of milk and mucus in a semi-digested state. There was no smell of opium; and not the slightest trace of morphia or meconic acid was detected in it on analysis, although the child had not vomited, but had remained throughout in a state of insensibility. The intestines were quite healthy. In the head, the blood-vessels of the brain were found much congested; but there was no effusion or extravasation of blood or serum. In all other respects, the brain presented its usual healthy characters. A case was communicated to me by Dr. Ogston, which was the subject of a trial at the Aberdeen Autumn Circuit, in Sept. 1853, in which a child, aged six months, died in a few hours from a dose of sixty drops
of wine of opium. The brain was congested to a marked extent. Although the dose was comparatively large, and death rapid, there was no decided indication of the presence of opium in the stomach. From this account of the appearances in the dead body, it will be seen that there is nothing but a fulness of the vessels of the brain, which can be looked upon as specially indicative of poisoning by opium, and even this is not always present. This congested condition of the brain, however, if it exist, can furnish no evidence of poisoning when taken alone, since it is so frequently found, as a result of morbid causes, in otherwise healthy subjects.

The occasionally anomalous nature of the symptoms and appearances in poisoning by opium, is well shown in a case communicated to me in November 1850, by Mr. Walter Clegg, Deputy Coroner for the County of Lincoln. A man, re. 56, in good health, swallowed by mistake in two pills from twenty-eight to thirty grains of the opium of commerce. This was at three o'clock in the morning, and he died rather suddenly at one o'clock in the day—i.e. ten hours after taking the drug. In about an hour after he had taken it he was heard to moan; there was twitching of the head and arms, and copious perspirations, with alteration of speech; but he retained his senses, was a little drowsy at intervals, and vomited occasionally. He dressed himself as usual in the morning, and complained of severe pain in his stomach. He was seen by a medical man about two hours before his death: there was no coma, contraction of the pupils, nor any other symptom of poisoning by opium. Even the vomited liquid had no smell of the drug. He walked in a trembling way. As it was not supposed that he could have swallowed opium, no emetic was given. After death, there was no fulness of the vessels of the brain or of its membranes, but there was such congestion at the greater end of the stomach as to lead to the supposition that irritant poison had been taken. No irritant poison was found, but there were distinct indications of opium. The poison appears in this case to have produced no effect on the brain, but to have exerted its influence chiefly on the nerves connected with speech and motion.

Quantity required to destroy life.—The medicinal dose of opium, in extract or powder, for a healthy adult, varies from half a grain to two grains. Five grains would be a very full dose. The medicinal dose of the tincture is from ten minims to one drachm,—as an average, from thirty to forty minims. The smallest dose of solid opium which has been known to prove fatal to an adult was in a case reported by Dr. Sharkey, of Jersey. A man, aged 32, died very speedily in a convulsive fit, after having taken two pills, each containing about one grain and a quarter of extract of opium. This quantity is equivalent to four grains of crude opium. (Med. Gaz. xiii. 236.) It is stated that Henrietta
Maria, the Queen of Charles L, was destroyed by a dose of three grains of opium. The smallest fatal dose of the tincture in an adult, which I have found recorded, is two drachms. The case is reported by Dr. Skae. (Ed. Med. and Surg. Journ. July, 1840.) The patient was a robust man, aged fifty-six;—he swallowed the tincture at ten in the morning, and died under the usual symptoms the following morning; the case having lasted only twelve hours. The quantity actually swallowed, however, appears to be involved in some doubt; for it is subsequently stated (p. 160) that half an ounce of laudanum may have been taken. Very large doses of the tincture have frequently been taken without proving fatal. I have elsewhere recorded a case in which five ounces of laudanum were taken without producing sleep, and the patient recovered. (Gny's Hosp. Reports, Oct. 1850, p. 220.)

Action of opium on infants.—In connection with this subject, it is important for a medical jurist to bear in mind that infants and young persons are liable to be killed by very small doses of opium; they appear to be peculiarly susceptible of the effects of this poison. Dr. Ramisch, of Prague, met with an instance of a child, four months old, that was nearly killed by the administration of one grain of Dover's powder, containing only the tenth part of a grain of opium;—the child suffered from stupor and other alarming symptoms. The following case occurred in June 1822. Four grains of Dover's powder (containing less than half a grain of opium) were given to a child four years and a half old. It soon became comatose, and died in seven hours. Death was referred to inflammation of the throat, and the jury returned the usual meaningless verdict of "Died by the visitation of God;" but there was no doubt, from the evidence, that death was caused by the opiate medicine. Dr. Kelso also met with an instance in which a child, nine months old, was killed in nine hours by four drops (minims?) of laudanum, equal to only one-fifth part of a grain of opium: it was much convulsed before death. A case is referred to in the Medical Gazette, in which two drops (minims?) of laudanum, equal to the tenth part of a grain of opium, killed an infant. The following is a more recent illustration of the fatal effects of a similar dose. A nurse gave to an infant, five days old, two drops (minims?) of laudanum, about three o'clock in the morning. Five hours afterwards the child was found by the medical attendant in a state of complete narcotism. It was revived by a cold bath, but a relapse came on, and it died the same evening, about eighteen hours after the poison had been given to it. On inspection, the brain and abdominal viscera were found in a perfectly healthy state, and there was no smell of opium in the stomach. (Prov. Med. Journ. Oct. 28, 1846, p. 519.) The fatal dose here, as in the former case, was equal to the tenth part of a.
grain of opium, and to only an infinitesimal dose of morphia! Dr. E. Smith has reported a case (Lancet, April 15, 1854), in which an infant, seven days old, died in eighteen hours from the effects of one minim of the tincture, or the twelfth part of a grain of opium. Coma with the usual symptoms was complete in half an hour. On inspection, the heart was found distended with black liquid blood; the lungs were collapsed but not congested. The brain was congested, but there was no effusion either into the ventricles or on the surface. The foramen ovale was still quite open. (See also Med. Times and Gazette, April 15, 1854, p. 386.) The smallest fatal dose recorded (in an infant) was in a case communicated to me by Dr. Edwards of Liverpool (November, 1857). An infant, four weeks old, died from the symptoms of poisoning by opium, in seven hours after a dose of paregoric elixir, equivalent to one nineteenth of a grain of opium, had been administered to it. In some instances infants have been found to manifest an astonishing power of recovery. Dr. Guy met with a case in which an infant of six months recovered after having had administered to it ten grains of Dover's powder, equal to one grain of opium (Lancet, June 8, 1850); and Mr. Tubbs has informed me, that in a case which occurred in January 1852, an infant of nine months recovered under treatment from a dose of two teaspoonsfuls of laudanum, given by mistake. This quantity left by evaporation four grains of an impure extract of opium.

There is a difference of opinion respecting the strength of laudanum or the pharmacopoeial tincture of opium. According to some, one fluid drachm, or sixty minims of the tincture, contains five grains of opium, while the London Pharmacopoeia assigns only about three grains. The strength of the tincture as it is procured of different druggists varies greatly. (See Pereira, Mat. Med. Vol. ii. Part ii. p. 647; also Lancet, March 12, 1853, p. 251.)

**Period at which death takes place.—** It has been remarked, that most cases of poisoning by opium prove fatal in from about six to twelve hours. They who recover from the stupor, and survive longer than this period, generally do well; but from some cases which have occurred, it would seem that there may be a partial recovery, or a remission of the symptoms, and afterwards a relapse. The symptoms, however, generally progress steadily to a fatal termination, or the stupor suddenly disappears, vomiting ensues, and the individual recovers. Several instances are recorded of this poison having destroyed life in from seven to nine hours. One has occurred within my knowledge, in which an adult died in five hours after taking the drug prescribed for him by a quack. Dr. Christison met with a case which could not have lasted above five, and another is mentioned by him which lasted only three hours. Dr. Beck quotes a
case which proved fatal in two hours and a half. (Beck, Med. Jur. 873.) The most rapid case of death yet reported, was that of a soldier who was accidentally poisoned, in September, 1846, in the Hospital of Val-de-Grâce. It appears that he swallowed by mistake about an ounce of laudanum, and died in convulsions in three-quarters of an hour. (Journal de Médecine, Oct. 1846, p. 475. For a similar case, see Med. Gaz. xlv. 743.) It is possible that the drug may even kill with greater rapidity than this; but, as a medico-legal fact, we are at present entitled to state, that it has destroyed life within the short period above mentioned. On the other hand the cases are sometimes much protracted. There are several instances of death in fifteen or seventeen hours. I have known one case fatal in twenty-two hours, and among those collected by Dr. Christison, the longest lasted twenty-four hours. (Op. cit. 712.)

Poisoning by Poppies.

The heads of the white poppy grown in this country have a narcotic action. They yield an insipidated extract called English opium, which, according to Mr. Hennell, contains five per cent. of morphia. The white poppy-heads, therefore, yield to water, in the form of decoction, a poisonous substance capable of acting deleteriously on children. Many cases of poisoning have occurred from the injudicious use of Syrup of poppies, which is nothing more than a sweetened decoction of the poppy-heads. This syrup is said to contain one gravis of extract (opium) to one ounce (Thomson). The common dose of it, for an infant three or four months old, is half a drachm; for adults, two to four drachms (Pereira, Vol. ii. Pt. ii. p. 643). There is some reason to believe that what is oft sold by many druggists for syrup of poppies as a soothing or cordial medicine for children, is nothing more than a mixture of tincture or infusion of opium with simple syrup; it is therefore a preparation of very variable strength. This may account for what appears to many persons inexplicable, namely, that an infant may be destroyed by a very small dose. In January, 1841, a child six months old is said to have died from the effects of less than half a teaspoonful of syrup of poppies bought at a retail druggist's. The narcotic symptoms were fully developed in three quarters of an hour. The syrup in this case probably contained tincture of opium. Seven children are reported to have lost their lives by this syrup in 1837-8. In one of these cases, a teaspoonful and a half was given. Stupor came on in half an hour, and the child died the following day. A teaspoonful has been known to prove fatal to a healthy child. (Pereira, Vol. ii. Pt. ii. p. 644.)
**GODFREY'S CORDIAL.**

This is chiefly a mixture of infusion of sassafras, treacle, and tincture of opium. The quantity of tincture of opium contained in it is stated by the late Dr. Paris to be one drachm in six ounces of the mixture, or half a grain of opium to one ounce: but it is very probable that, like the so-called syrup of poppies, its strength is subject to great variation. A case has been reported, in which half a teaspoonful, = 1-32nd part of a grain of opium, was alleged to have caused the death of an infant. In 1837-8, twelve children were admitted to have been killed by this mixture alone. The explanation of this is, that the medicine is given in large doses by very ignorant persons.

**DALBY'S CARMINATIVE.**

This is a compound of several essential oils and aromatic tinctures in peppermint water, with carbonate of magnesia and tincture of opium. According to the late Dr. Paris there are five minims of the tincture, or one quarter of a grain of opium, in rather more than two ounces of this mixture, or the one-eighth of a grain in an ounce. The formula commonly given is—carbonate of magnesia two scruples, oil of peppermint one minim, of nutmegs two minims, of aniseed three minims, tincture of opium five minims, spirit of pennyroyal and tincture of assafoetida of each fifteen minims, tincture of castor and compound tincture of cardamoms of each thirty minims, and of peppermint water two ounces. According to this formula, tincture of opium forms the 1-211th part by measure, or one teaspoonful would contain the 1-64th part of a grain of opium. Like most of these quack preparations, it probably varies in strength. An infant is reported to have been destroyed by forty drops of this nostrum—a quantity, according to the strength assigned, equivalent to more than two minims of the tincture, or from one-sixth to one-tenth of a grain, of opium. Accidents frequently occur from its use, partly owing to ignorance, and partly to gross carelessness on the part of mothers and nurses.

**PAREGORIC ELIXIR. COMPOUND TINCTURE OF CAMPHOR.**

This is a medicinal preparation of alcohol, opium, benzoic acid, oil of aniseed, and camphor. Opium is the active ingredient, and of this, the tincture contains rather less than one grain in every half ounce (nine grains to five ounces). In one case of poisoning by this tincture, a child aged seven months died from the effects of a teaspoonful (equal to one quarter of a grain of opium), given in two doses at an interval of a day. (Pharmacetical Journal, April 1845.) But an infant has been killed by a dose equivalent to not more than the ninetieth part of a grain of opium. (Anie, p. 164.)
POISONING BY MORPHIA. SYMPTOMS AND APPEARANCES. 167

DOVER'S POWDER. (PULV. IPECAC. COMP.)

This is a preparation of opium, the effects of which on young children have been already adverted to. The proportion of opium is one-tenth part, or one grain in every ten grains of the powder. A child has been killed by four grains; therefore by a quantity containing about two-fifths of a grain of opium. On the other hand, Dr. Guy has reported a case in which an infant of six months recovered, under active treatment, from a dose of ten grains. (Lancet, June 8, 1850.)

MORPHIA AND ITS SALTS.

Morphia and its saline combinations must be regarded as active poisons. The pure alkaloid is known from its salts by its great insolubility in water; and owing to this property some have regarded it as less poisonous. The acid secretions of the stomach would, however, dissolve it in sufficient quantity to produce, very speedily, dangerous effects. The two principal salts of morphia are the muriate and the acetate.

Symptoms.—They generally commence in from five to twenty minutes after the dose of poison has been swallowed; and they very closely resemble those observed in poisoning by opium. As a summary, it may be stated that they consist in dimness of sight, weakness and relaxation of the muscular system, tendency to sleep, stupor, loss of consciousness, coma, stertorous respiration, and more commonly than in poisoning by opium, there are convulsions. According to Orfila, in nineteen-twentieths of all cases the pupils will be found strongly contracted, a statement which I believe to be correct; the few exceptional cases were those in which the dose was excessive, and the symptoms were unusually violent. The state of the pupils gave rise to great difference of opinion among the medical witnesses on the trial of Dr. Castaign. (Orfila, ii. 185; On Poisons.) The condition of the pulse varies greatly. In some cases there is great irritability, as well as itching of the skin, and irritability of the bladder with difficulty of passing urine. Vomiting and purging have been met with in those instances in which the dose was large.

Appearances.—The only appearance which can be referred to the action of morphia is fulness of the cerebral vessels, with occasionally serous effusion. These poisons have no local irritant action, and they therefore leave no marks of their operation in the stomach and bowels. An account of the appearances produced by an overdose of sulphate of morphia has been published by Orfila in a report of the case of Dr. Ellenberger. (Ann. d'Hyg. 1852, ii. p.359.) The case presents some curious features. The deceased imagined that he had discovered a certain antidote for morphia and its salts, and proposed, while Orfila was at Prague in October 1851, to swallow the poison and the antidote.
in his presence. Orfila consented to witness the experiment. A powder was produced, which was found to have a bitter taste, and to possess some of the chemical properties of morphia, evidently mixed however with some other substance. The Doctor swallowed about twenty-three grains of this powder, and immediately afterwards, his so-called antidote, which was a fine white powder having a sweetish taste. He did not suffer from any symptoms of poisoning. Orfila, with a keen eye to the practical use of antidotes, inquired whether he had ever allowed a certain interval to pass before taking the remedy. Dr. Ellenberger said that the results were the same. About six months afterwards, Dr. Ellenberger died from a dose of about ten grains of sulphate of morphia. He had taken his antidote, but not until a considerable interval had elapsed. A minute inspection of the body was made, and the principal appearance was a well-marked congestion of the brain and its membranes. Traces of sulphate of morphia were found in the stomach. The so-called antidote was examined, and found to consist of a mixture of magnesia and carbonate of magnesia.

**Black Drop.**

This is a preparation of opium, in which the morphia is combined with acetic acid, and very little meconic acid is present. In the black drop, according to Pereira (Mat. Med. Vol. ii. Pt. ii. p. 650), vinegar, the juice of the wild crab, is employed as a menstruum instead of vinegar. The black drop is considered to have from three to four times the strength of the tincture of opium. The formula for this preparation will be found in Dr. Neligan’s work, On Medicines, &c., p. 235. According to this, it is a compound of half a pound of opium to three pints of the expressed juice of the wild crab. It resembles the *Acetum Opii*, and has more than twice the strength of laudanum.

**Sedative Solution. (Batitley’s.)**

This is an aqueous solution of opium with a little spirit and less meconic acid than the common tincture. (Pereira, Vol. ii. Pt. ii. p. 646.) It is considered to have three times the strength of tincture of opium; but there is so great a difference of opinion on this point, that Dr. Neligan represents it as being only of about the same strength as laudanum. (Medicines, &c., p. 236.) He states that it is composed of three ounces of extract of opium, six drachms of spirit, and as much distilled water as will make up two pints. It appears to be an energetic preparation. Mr. Streeter stated at the Westminster Medical Society, Dec. 1838, that he had known one drachm and a half of it prove fatal to a lunatic; and twenty minims of the solution destroyed the life of an old woman. A medical gentleman, lying dangerously ill from an attack of dysentery, took, by mistake,
about seven drachms of Battley's solution. Within five minutes, salt and water, with mustard, were administered, and twenty-four grains of sulphate of zinc. Vomiting ensued; the emetic was repeated, and with the same effect; the fluid evacuated at the second vomiting, having the usual smell of opium. Half a drachm of ipecacuanha was subsequently given to complete the emptying of the stomach. Norwithstanding repeated vomiting, symptoms of narcotism presented themselves speedily, with contraction of the pupils, and great drowsiness—rendering it necessary to remove the patient from bed in his very debilitated state, and keep him constantly moving, until about 9 P.M. (seventeen hours), when vomiting came on spontaneously, and he was put to bed, and allowed to sleep. The original disease afterwards resumed its course (complicated by an attack of gastritis), and at length terminated favourably; but the patient had no recollection whatever of what occurred for twenty-four hours after the administration of the emetics; and it appeared to his medical attendants that an excited state of mind remained for some days afterwards. (Prov. Journ., Jan. 28, 1846, p. 42.) The death of Dr. Badeley, of Chelmsford, from a dose of this solution taken medicinally, furnishes an additional proof of the dangerous uncertainty in the strength of this preparation.

Chemical analysis. Opium.—There are no means of detecting opium itself, either in its solid or liquid state, except by its smell and other physical properties, or by exhibiting a portion of the suspected substance to animals, and observing the effects produced. The smell is said to be peculiar, but a similar smell is possessed by lactucaarium, which contains neither meconic acid nor morphia. The odour is a good concomitant test of the presence of the drug, whether it be in a free state, or dissolved in alcohol or water, but it is not perceptible when the solution is much diluted. I found that half a grain of powdered opium, dissolved in half an ounce of water, lost its characteristic smell by a short exposure. The odour is decidedly volatile, and passes off when an opiate liquid is heated; it also escapes slowly at common temperatures. Again, it may be easily concealed by other odours, or the drug may undergo some change in the stomach during life which may destroy the odour. The analysis in cases of poisoning by opium is therefore limited to the detection of morphia and meconic acid.

Morphia.—Morphia is known by the following properties:—
1. It crystallises in fine prisms, which are white and perfect, according to their degree of purity. 2. When heated on platina, the crystals melt, become dark-coloured, and burn like a resin with a yellow smoky flame, leaving a carbonaceous residue. If this experiment be performed in a small reduction-tube, it will be found, by employing test-paper, that ammonia is one of the
products of decomposition. 3. It is scarcely soluble in cold water, as it requires 1000 parts to dissolve it: it is soluble in one hundred parts of boiling water, and the hot solution has a faint alkaline reaction. By its insolubility in water it is readily known from its salts. It is not very soluble in ether, thus differing from narcotina; but it is dissolved by forty parts of cold, and rather less than this quantity of boiling alcohol. It is soluble in oils and in the caustic alkalies (potash). 4. It is easily dissolved by a very small quantity of all diluted acids, mineral and vegetable. 5. It has a bitter taste.

Tests. — In order to apply the chemical tests for morphia, the alkaloid may be dissolved in a few drops of a diluted acid, either the acetic or muriatic. If the muriate or the acetate of morphia be presented for analysis it may be at once dissolved in a small quantity of boiling water. The tests for this alkaloid are the following: 1. Nitric acid. This, when added to a moderately strong solution of a salt of morphia, produces slowly a deep orange-red colour. If added to the crystals of morphia or its salts, deoxide of nitrogen is evolved: — the morphia becomes entirely dissolved, and the solution acquires instantly the deep red colour above described,—becoming, however, lighter by standing. In order that the effect should follow, the solution of morphia must not be too much diluted, and the acid must be added in pretty large quantity. The colour is rendered much lighter by boiling; therefore, the test should never be added to a hot solution. 2. Permutate of iron (sesquichloride), or colourless persulphate. Either of these solutions, when saturated and neutralised (by a small quantity of potash if necessary), produces an inky-blue colour in a solution of morphia. If the quantity of morphia be small, or the test have a deep red or yellow tint, the colour is greenish. The blue colour is entirely destroyed by acids,—it is also destroyed by heat: thus the iron-test should never be employed with a very acid or a very hot solution of a salt of morphia. It may be observed, that the blue given by the test in a solution of morphia is entirely destroyed by nitric acid and replaced by an orange-red colour, so that the nitric acid will act through the iron-test, but not vice versa. In this way two tests may be applied to one quantity of liquid. 3. Iodic acid. Morphia in the solid state or in solution decomposes this acid, taking part of its oxygen, and setting free iodine. In order to make this evident, the iodic acid should be first mixed with starch; and a part of this mixture only, added to the suspected solution,—part being reserved, to allow of a comparison. If the iodic acid be added to a solution of morphia without starch, the liquid becomes brown, and smells of iodine. When the quantity is very small, there is only a reddish or purple tint slowly produced: — when large, the dark-blue iodide of farina is formed in a few seconds. This colour being destroyed by heat,
the test must not be added to a hot solution. This test succeeds equally well with morphia or its salts, when unmixed with organic matter; but the analyst must remember, that the blue iodide of farina forms a colourless combination with a large quantity of starch: hence but little of this substance should be used, if the quantity of morphia be small. 4. Sulphuric acid and bichromate of potash. When strong sulphuric acid is poured on pure morphia in a solid state, there is either no effect, or the alkaloid acquires a light pinkish colour. On adding to this a drop of solution of bichromate of potash, or a small fragment of a crystal, it immediately becomes green (from oxide of chrome), and retains this colour for some time. Other alkaloids (strychnia) are not thus affected. Narcotins is turned of a bright yellow by sulphuric acid; therefore, although it becomes green when mixed with bichromate of potash, it could not be mistaken for morphia: besides, the green rapidly passes to a dingy brown colour.

Meconic acid.—This is a solid crystalline acid, seen commonly in scaly crystals of a reddish colour. It is combined with morphia in opium, of which, according to Mulder, it forms on an average six per cent. (Brande’s Chemistry, Vol. ii. p. 1403); and it serves to render that alkaloid soluble in water and other menstrua.

Tests.—Many tests have been proposed for meconic acid; there is only one upon which any reliance can be placed, namely, the Permuriate or Persulphate of iron. This test gives, even in a very diluted solution of meconic acid, a deep red colour; and it is owing to the presence of this acid that the salt of iron causes a deep red colour in tincture and infusion of opium, as well as in all liquids containing traces of meconate of morphia, the effects of the iron-test with morphia being counteracted by the presence of meconic acid. The red colour of the meconate of iron is not easily destroyed by diluted mineral acids, by a solution of corrosive sublimate, or by chloride of gold, but it is by sulphurous acid and chloride of tin. In liquids containing tannic acid, e.g. tea or beer, the action of this test is obscured.

Detection of opium in organic mixtures.—Opium itself may be regarded as an organic solid, containing the poisonous salt which we wish to extract. It is not often that, in fatal cases of poisoning by opium or its tincture, even when these are taken in large quantity and death is speedy, we can succeed in detecting meconate of morphia in the stomach. It is probably removed by vomiting, digestion, or absorption. If the matter be solid, it should be cut into small slices; if liquid, evaporated to an extract; and in either case, digested with distilled water and a small quantity of acetic acid for one or two hours at a gentle heat. The aqueous solution should be filtered, some acetic acid added, and then treated with acetate of lead, until there is no further precipitation. The liquid should be boiled and filtered.
meconate of lead is left on the filter, while any morphia passes through under the form of acetate. The surplus acetate of lead contained in the filtered liquid (containing the morphia) should now be precipitated by a current of sulphuretted hydrogen—the sulphuret of lead separated by filtration, and the liquid evaporated at a very gentle heat to an extract, so that any sulphuretted hydrogen may be entirely expelled. On treating this extract with alcohol, the acetate of morphia, if present in sufficient quantity, may be dissolved out and tested. The meconate of lead left on the filter may be decomposed by boiling it with a small quantity of diluted sulphuric acid; and in the filtered liquid, neutralised if necessary by an alkali, the meconic acid is easily detected by the iron-test. This analysis requires care as well as some practice in the operator, in order that the morphia should be obtained in a sufficiently pure state for the application of the tests. Before resorting to this process, it is advisable to employ trial tests on the original liquid, in order to determine whether any meconic acid or morphia be present or not. The smell of opium may be entirely absent. The best trial tests are nitric acid and the permuriate of iron. These will produce in the infusion or liquid, if it contain opium, the changes already indicated. In testing for meconic acid, it is advisable to dilute the organic liquid, if coloured, with a sufficient quantity of water to render the production of a change of colour by the test perceptible. In respect to this method of detecting the meconate of morphia in a suspected liquid, it is proper to observe, that nitric acid will indicate the presence of morphia, and permuriate of iron the presence of meconic acid, in infusions containing so small a quantity of opium as not to be precipitated by the acetate of lead.

The separation and detection of meconic acid is a comparatively simple process. It has been found in no vegetable substance excepting opium; hence, before pronouncing this drug to be present, the presence of this acid in the suspected liquid should be clearly determined. It has been erroneously asserted that the extract of taraxacum (dandelion) contained a resinoid matter, which might by its reactions be mistaken for morphia. This, however, is not the case: taraxacum contains no meconic acid and no alkaloid resembling morphia. The statement appears to have arisen from a too confident reliance on the colour produced by the application of tests to organic liquids. (See Medical Times and Gazette, Aug. 29, 1857, p. 229, and Oct. 17, p. 406; also Guy's Hospital Reports, October, 1857, p. 497.)
CHAPTER XVII

PRUSSIC ACID—DIFFERENCES IN STRENGTH—TASTE AND ODOUR
— CONDITIONS UNDER WHICH THE ODOUR MAY AND MAY
NOT BE DETECTED—SYMPTOMS PRODUCED BY SMALL AND
LARGE DOSES—PERIOD AT WHICH THE SYMPTOMS COMMENCE
— POWER OF VOLITION AND LOCOMOTION—APPEARANCES—
QUANTITY REQUIRED TO DESTROY LIFE—FATAL DOSE—PERIOD
AT WHICH DEATH TAKES PLACE—TESTS FOR THE ACID—
VAPOUR TESTS—PROCESS FOR ORGANIC MIXTURES. BITTER
ALMONDS. NOYAU. CYANIDE OF POTASSIUM.

General remarks.—Hydrocyanic, or Prussic Acid, owing to
its rapid and unerring effects when taken even in comparatively
small doses, is one of the most formidable poisons with which we
are acquainted. As it is sold in shops, it varies considerably in
strength. I have found different specimens to contain from 1·3
to 6·5 per cent. of the strong acid; but two varieties are now
commonly met with—1. The prussic acid of the London Phar-
macopœia, containing about two per cent. (Phillips.) 2. Scheele’s
acid, containing from four to five per cent. In a case of poison-
ing which I was required to investigate in July 1847, the acid
which was sold for Scheele’s was found to contain only two per
cent! (Med. Gaz. xl. p. 171.) In another instance there was the
same deficiency of strength. In short, there is no certainty re-
specting the strength of any two specimens sold as Scheele’s acid,
—a subject which demands the serious consideration of medical
practitioners who prescribe it.

Taste and odour.—The evidence derivable from the taste and
odour of this poison is, in some instances, of importance. The
taste is described by Dr. Christison as pungent; some state that
it is hot, others that it is bitter (Pereira). In one fatal case
(December 1856) deceased complained, on swallowing about a
drachm of the poison by mistake, that it had a bitter taste. When
the common acid is taken mixed with organic liquids, a taste
is not likely to be perceptible unless the dose be large.

With regard to the odour, Dr. Christison states that when
diffused, it has a distant resemblance to that of bitter almonds;
but it is accompanied with a peculiar impression of acridity on
the nostrils and back of the throat. (Op. cit. 752.) Orfila also
says that it is similar to that of bitter almonds;—this is, indeed,
the common impression. There is, however, a difference between
these odours; but the difference is not perceptible to the senses
of all, and the only practical point requiring notice is, that the
diluted odour of bitter almonds would probably be pronounced
by many to indicate the presence of prussic acid, especially if
there existed any suspicion of violent death. Even experienced
medical men have to my knowledge been deceived on this point. There are some who are unable to perceive the odour of prussic acid when it exists in large proportion, whether mixed with water or other liquids; while others, again, are peculiarly susceptible of it. With some, it does not affect the olfactory nerves at all, but produces merely a sense of constriction in the fauces. These facts appear to me to explain,—why, on being called to a case of poisoning by this acid, or during the examination of a body, some medical men perceive the odour while others do not. When many have to form a judgment on this subject, it is much more common to find disagreement than unanimity. In a case seen by Dr. Christison, in which a man had swallowed a large dose of prussic acid, there was no odour in the breath near the patient nor in any part of the room. Two friends could not perceive any odour in six ounces of the warm fluid freshly drawn from the stomach by the pump. (Ed. Month. Jour. Feb. 1850, p. 97.) In other instances the odour may be completely concealed by other odours. In a case communicated to me in May 1850, by Mr. Rake, of Newark, a man swallowed a large dose of prussic acid, and was afterwards observed walking and smoking his pipe. He was found dead in a privy very shortly afterwards; but although the body was still warm, the smell of tobacco-smoke from the mouth completely overpowered and concealed the odour of prussic acid. On opening the body, the smell of the acid was at once perceptible.

Symptoms. — The time at which the symptoms of poisoning commence in the human subject, is liable to great variation from circumstances not well understood. When a large dose has been taken, as from half an ounce to an ounce of the diluted acid, the symptoms usually commence in the act of swallowing, or within a few seconds. It is rare that their appearance is delayed beyond one or two minutes. When the patient has been seen at this period, he has been perfectly insensible, the eyes fixed and glistening, the pupils dilated and unaffected by light, the limbs flaccid, the skin cold and covered with a clammy perspiration;—there is convulsive respiration at long intervals, and the patient appears dead in the intermediate time; the pulse is imperceptible, and involuntary evacuations are occasionally passed. The respiration is slow, deep, gasping, and sometimes heaving, or sobbing. The following case was communicated to me by Mr. French: it presents a fair example of the effects of this poison in a large and fatal dose. A medical man swallowed seven drachms of the common prussic acid. He survived about four or five minutes, but was quite insensible when discovered, i.e. about two minutes after he had taken the poison. He was found lying on the floor, senseless,—there were no convulsions of the limbs or trunk, but a faint flickering motion was observed about the muscles of the lips. The process of respiration ap-
peared to cease entirely for some seconds: it was then performed in convulsive fits, and the act of expiration was remarkably deep, and lasted for a very long time. The deceased swallowed the poison while ascending a staircase; his body was found on the landing. The bottle had rolled some distance from him, and the stopper was lying in another direction. Simon mentions a case in which an ounce was taken, and the symptoms were precisely similar. There was besides coldness of the hands and feet; and no pulse could be felt. In such cases, i.e. when the dose is large, the breath commonly exhales a strong odour of the acid. Convulsions of the limbs and trunk, with spasmodic closure of the jaws, are usually met with among the symptoms; the finger-nails have been found of a livid colour, and the hands firmly clenched.

The breathing is generally convulsive, but when the coma or insensibility is profound, it is sometimes stertorous. This was noticed in a case which occurred to Dr. Christison (Edinburgh Monthly Journal, February, 1850, p. 97). It was also observed in the case of Marcooley (Reg. v. Burroughs, C.C.C., February, 1857). Stertorous breathing has not been hitherto recorded by toxicologists as one of the symptoms of poisoning by prussic acid. In the inquiry which took place at Rugeley, in January 1856, respecting the death of Walter Palmer, it was contended that the fact of the deceased having had stertorous breathing was a proof that he had died from apoplexy, and not, as it was alleged, from prussic acid, administered to him by his brother, William Palmer; but the facts here recorded show that such an inference is inadmissible. On the other hand, there were moral circumstances which rendered it highly probable that deceased might have had a dose of prussic acid administered to him shortly before his death, and that he had really died from its effects.

When a small dose (i.e. about thirty minims of a weak acid) has been taken, the individual has first experienced weight and pain in the head, with confusion of intellect, giddiness, nausea, a quick pulse, and loss of muscular power; these symptoms are, however, sometimes slow in appearing. Vomiting has been occasionally observed, but it is more common to find foaming at the mouth, with suffusion or a bloated appearance of the face, and prominence of the eyes. If death result, this is preceded by tetanic spasms, opisthotonos, and involuntary evacuations. Vomiting is sometimes the precursor of recovery. (See cases in Medical Gazette, xxxvi. 103; xxxv. pp. 859, 893.) A case which occurred to Mr. Bishop (Prov. Med. and Surg. Jour. Aug. 13, 1845, p. 517) was remarkable in several particulars: the individual swallowed, it was supposed, forty minims of an acid (at three and a quarter per cent.), and was able to give an account of his symptoms. He was conscious for some time after he had
taken it, and he recollected experiencing the sensation of his jaws becoming gradually stiff and tight.

*Period at which the symptoms commence. Power of volition and locomotion.* — One of the most marked effects of prussic acid is to produce insensibility, and loss of muscular power, much more speedily than any other poison. In some instances, there may be loss of consciousness in a few seconds; in others, certain acts indicative of volition and locomotion may be performed, although requiring for their performance several minutes. This is one of the most important questions connected with death by prussic acid. In treating of this subject, Dr. Lonsdale says, that a drachm of Scheele’s acid would affect an ordinary adult *within a minute*; and if the dose were three or four drachms, it would exert its influence within ten or fifteen seconds. When the acid is stronger and the quantity larger, we are pretty certain of its *immediate* action, and the consequent annihilation of the sensorial functions. (Ed. Med. and Surg. Jour. ii. 30.) Mr. Nunneley found that in some instances the action of the poison was so expeditious as to prevent the least indication of voluntary motion: but in the majority of dogs, about twenty seconds elapsed before any symptoms were manifested. (Pro. Trans. N. S. iii. p. 75.) Dr. Gerecke gave a teaspoonful of concentrated prussic acid to a doe; symptoms were *instantaneously* produced, and in three seconds the animal was dead. (Casper’s Wochenschrift, 26 Sept. 1846, p. 615.) In his evidence in the case of *Rex v. Freeman* (Leicester Spring Assizes, 1829), Mr. Macaulay stated that in one experiment a dog was killed in three seconds; and Dr. A. Thomson has observed that a dog has been killed in two seconds. (See *On Poisons.*) Dr. Christison ascertained that a quantity of poison, equivalent to two scruples of medicinal acid, did not begin to act on a rabbit for twenty seconds, and, for so small an animal, he considers two scruples to be as large a dose as *five drachms* given to a grown-up girl. (Op. cit. p. 757.) These very different results appear to me to show clearly that experiments on animals cannot enable us to give a satisfactory solution of this question. We should rather trust to the few observations made on the human subject, as well as to analogy from other sources, —as, for example, to the fact of survival, after the infliction of what are commonly regarded as instantaneously mortal wounds.

*Appearances.* — The body often exhales the odour of prussic acid when seen soon after death; but if it has remained exposed for some time before it is seen, and especially if it has been exposed to the open air or in a shower of rain, the odour may not be perceptible: again, as in a case already related, the odour may be concealed by tobacco-smoke, peppermint, or other powerful odours. In a case in which a person poisoned himself with two ounces of the acid, and his body was examined twenty-eight hours after death, the vapour of prussic acid which escaped on
opening the stomach, was so powerful that the inspectors were seized with dizziness, and obliged to quit the room hastily. This may serve as a caution in conducting an examination. In cases of suicide or accident, the vessel out of which the poison has been taken will commonly be found near; but there is nothing to preclude the possibility of a person throwing it from him in the last act of life, or even concealing it, if the appearance of the symptoms should be delayed. (See post, case by Dr. Christie, page 178.) Owing to the great volatility of the poison, the vessel may, if left uncorked, not retain the odour when found. Putrefaction is said to be accelerated in these cases; but from what I have been able to collect, there seems to be no ground for this opinion, any more than in a case of poisoning by opium. (See case in Prov. Med. Jour. July 30, 1845.) Orfila has shown that in most instances of sudden death, from whatever cause, putrefaction is, ceteris paribus, accelerated; and the fact that in one or two instances of death from prussic acid, the bodies have speedily putrefied, has improperly led to this condition being set down as one of the characters of poisoning by the acid.

The appearances in the body are very slight. Externally, the skin is commonly livid, or is tinged of a violet colour; the nails are blue, the fingers clenched, and the toes contracted; the jaws firmly closed, with foam or froth about the mouth, the face often pallid, but sometimes bloated and swollen, and the eyes have been observed to be wide open, fixed, glassy, very prominent and glistening, and the pupils dilated: but this condition of the eyes has been observed in other kinds of death. Internally, the venous system is gorged with dark-coloured blood: the stomach and alimentary canal are in their natural state; but in several instances they have been found more or less reddened. The mucous membrane of the stomach of a dog which died in a few minutes from a dose of three drachms of Scheele's acid, was intensely reddened throughout, presenting the appearance met with in cases of arsenical poisoning. In a large number of experiments upon dogs, Mr. Nunnleley states that he found generally a congested condition of the mucous membrane of the stomach: if empty at the time the poison was taken, the organ was found much contracted, and of a brick-red colour. This appearance of congestion was observed on the mucous membrane of the vagina, the rectum, and conjunctiva, when the acid was applied to these parts. (Prov. Trans. N.S. iii. p. 79.) Redness of the stomach was noticed in the case of the Parisian epileptics (Annales d'Hygiène, 1829, i. 507). Dr. Geoghegan, of Dublin, has communicated to me the particulars of a case in which this redness of the mucous membrane was well marked. In April 1847, a healthy man, aged 30, swallowed a large dose of prussic acid. He was soon afterwards found dead in his bed. The body was
inspected five hours afterwards: rigidity had commenced, but there was some warmth. The face was pale, the eyes half closed, not presenting any remarkable brilliancy or prominence, and there was great dilatation of the pupils. The mouth was closed, and no froth issued from it. The abdomen was the only cavity examined. The muscles were red, and gave out, on section, a good deal of fluid blood, which had a strong odour of prussic acid; the odour of the poison was also perceptible in the abdomen. About eight ounces of a thick farinaceous mass were found in the stomach; the odour of prussic acid was very perceptible in this organ, but it was mixed with that of rancid food. The mucous membrane had everywhere, except at the greater end and posterior wall, a vivid inflammatory redness, of a well-marked character, and it was covered with a layer of viscid mucus to a considerable extent. The coats were not thickened, but the submucous coat presented ramified redness; the peritoneal coat was also decidedly red. The posterior wall, at the splenic end, was of a chocolate colour, with spots of effused blood; the great venous trunks stood out in relief as dark blue lines. The mucous membrane, even when washed three times in water, gave out a strong odour of prussic acid. In a case which I examined in May 1850, in which death had been caused by a large dose of the acid, there was also a general redness of the stomach. Hence an irritant action may be fairly assigned to this poison.

Quantity required to destroy life.—This is a very important question; and it is made somewhat perplexing by the fact, that beyond a certain dose, the weak and the strong acid appear to act with equal rapidity. (Christison, 658.) The smallest dose which is reported to have caused death, was in a case which occurred to Mr. Hicks. (Med. Gaz. xxxv. 896.) The female, a healthy adult, died in twenty minutes from a dose equivalent to nine-tenths of a grain of anhydrous prussic acid. This was equivalent to forty-nine grains of the London Pharmacopoeial acid; and taking Scheele’s acid at five per cent., to about twenty grains of this acid. In a case reported by Mr. T. Taylor (Med. Gaz. xxxvi. 104), a stout healthy man swallowed this dose, i.e., nine-tenths of a grain, by mistake, and remained insensible for four hours, when he vomited and began to recover. The vomited matters had no odour of the poison, showing that if not concealed by other odours the whole of the acid must have been here absorbed. He had a very narrow escape of his life. Dr. Banks has published a case in which a female recovered after swallowing thirty drops of prussic acid (Ed. Med. and Surg. Journ. xlviii. p. 44); but the interest of this case is lost owing to the strength of the acid not having been determined.

Recoveries from large doses.—The largest dose from which an adult has recovered, was probably in a case which has been re-
ported by Mr. Burman, (Lanceet, Jan. 14, 1854). His father, aged 60, and of a strong constitution, took by mistake a drachm of prussic acid, equivalent to 2-4 grains of anhydrous acid. In a few seconds he perceived the mistake, and swallowed half an ounce of aromatic spirits of ammonia with a little water. He called to his son; told him what had occurred; spoke hurriedly and breathed deeply. Some solution of green sulphate of iron was given two minutes after the poison had been swallowed. Insensibility then came on, and the respiration was deeper and slower. Four minutes after taking the poison cold affusion was employed, and sulphate of iron and spirits of ammonia administered. Vomiting with convulsive shuddering took place. In twenty minutes consciousness returned, and fifteen minutes later he was able to walk up stairs to bed. He perfectly recovered, but in the absence of the treatment resorted to, it is most probable that he would have died. Dr. Christison has reported in the Edinburgh Monthly Journal (Feb. 1850, p. 97) the case of an adult who recovered after having taken a dose of a grain and a half or two grains of anhydrous acid. The treatment consisted in the evacuation of the stomach by the stomach-pump, and in pouring a current of cold water on the head. The symptoms were such that the man would have died, but for immediate treatment. It is a remarkable fact that in this case no bottle or vessel could be found in the room or under the window. The patient hastily summoned his wife one evening, told her that he had taken prussic acid, and immediately fell down senseless on a sofa, without either cry or convulsion, but drawing his breath deeply, forcibly, and slowly. He recovered in about three hours, but had an unusual disposition to sleep even on the following day. Another remarkable case of recovery from a dose nearly as large, occurred to Mr. Bishop. (Prov. Med. Journ. Aug. 13, 1845, p. 317.) The person swallowed, it was supposed, forty minims of an acid at three and a quarter per cent. Taking the minim as equal to the grain, although it may be a little more or less according to circumstances, this is equivalent to about one grain and one-third of anhydrous acid. The man was for a short time conscious, got into bed after taking the poison, and spoke. He felt his jaw become stiff, and then remained insensible until roused by the cold affusion. The fact of recovery having taken place on these occasions must not lead us to suppose that such large doses could be commonly taken with impunity. If we refer to the chapters on arsenic and corrosive sublimate, we shall find that persons have recovered from doses of these poisons much larger than those which have proved fatal in other cases. The same circumstance is observed in respect to all other poisons. Judging by the effects produced in Dr. Geoghegan's case from 0·66 grain of anhydrous acid,—from the fact that death took place in Mr. Hicks's case from nine-tenths of a grain, and, that, in another
instance, a strong adult had a narrow escape of his life from the same dose, we shall not be wrong in assuming that a quantity of Scheele's acid (at five per cent.) above twenty grains (i.e. one grain of anhydrous acid), or an equivalent portion of any other acid, would commonly suffice to destroy the life of an adult. This I believe to be the nearest approach we can make to the smallest fatal dose. It is scarcely necessary to remark that the quantity of poison found in the stomach is the surplus of that which has actually destroyed life. On the trial of John Tawell, the Quaker (Bucks Lent Ass. 1845), it was made a great point in the chemical defence, undertaken by Mr. Herapath and Dr. Lethbye, that, as not more than one grain of anhydrous prussic acid was separated from the contents of the stomach, and this, in their opinion, was insufficient to have caused death, therefore the deceased could not have died from the effects of this poison! That an acute lawyer should make a perverted use of a scientific point for the purpose of obtaining a verdict from a jury, is not surprising: but that persons professing to be acquainted with the action of poisons should either suggest or allow suggestions to be made, the only tendency of which must be to mislead a jury on an important scientific question, is discreditable to medical science. I have elsewhere pointed out the danger of relying upon the necessity of discovering what is called a fatal dose of poison in a dead body. (See ante, Arsenic, p. 89.)

There appears to be no strict relation between grains, minims, and drops. I have found by experiment, that sixty minims (or one drachm) of the same prussic acid, at two per cent., measured in three different measures, weighed respectively 61, 62.5, and 64 grains (On Poisons), while sixty minims, dropped from an eight-ounce bottle, of the acid containing two per cent. were equivalent to 42 drops,—and the same measure of an acid at four per cent. was equivalent to 40 drops. The volume and weight of drops vary according to the nature of the liquid, the size of the bottle, the width of the lip of the bottle, and the angle of inclination. Hence it is a most uncertain mode of measuring, and in reference to doses I have here substituted "grains" for "drops."

Period at which death takes place.—When the dose is two drachms and upwards, we may probably take the average period for death at from two to ten minutes. In Mr. Hicks’s case, forty-nine grains of the Pharmacopoeia acid destroyed life in twenty minutes. It is only when the dose is just in a fatal proportion, that we find the individual to survive from half an hour to an hour. In this respect, death by prussic acid is like death by lightning,—the person in general either dies speedily or recovers altogether. According to Dr. Lonsdale, death has occurred in the human subject as early as the second, and as late as the forty-fifth minute. But although death does not commonly ensue
CHEMICAL ANALYSIS.

181

until after the lapse of a few minutes, insensibility, and consequently a want of power to perform acts of volition and locomotion, may come on sometimes in a few seconds. The time at which this loss of muscular power is supposed to take place, has frequently become an important medico-legal question; and on the answer to it the hypothesis of suicide or murder in a particular case may rest.

**Prussic Acid Vapour.**—Death may occur from the inhalation of the vapour of prussic acid, without any of the liquid entering the stomach. Insensibility was in one instance produced by the respiration of the vapour, arising from a small quantity of the acid spilled upon a dress. Dr. Regnauld has reported a case in which a student nearly lost his life by respiring the vapour of prussic acid, which escaped from a flask in which he was preparing the poison. He lay in a perfectly insensible state for many hours. There was a slight lividity of the face, the eyelids were closed, and the pupils widely dilated; respiration was difficult and took place at intervals—extremities cold, pulse barely perceptible. The muscles of the arms and legs were firmly contracted, but there were no tetanic convulsions. The patient was in a state of complete coma, and could not be roused. After some hours recovery took place, but the patient suffered from headache and other symptoms. (Ann. d’Hyg. 1852, i. 455.)

**Chemical analysis.**—Prussic acid is limpid like water; it possesses a faint acid reaction, and its vapour has a peculiar odour, which, when the acid is concentrated, although not at first perceptible, is sufficient to produce giddiness, insensibility, and other alarming symptoms. The tests which are best adapted for the detection of this poison, either in liquid or vapour, are equally applicable whether the acid be concentrated or diluted, and, so far as the detection of the vapour is concerned, whether it be pure or mixed with organic matter. In the simple state, the tests are three in number: the Silver, the Iron, and the Sulphur tests.

1. **The Silver Test.**—**Nitrate of Silver.**—This yields, with prussic acid, a dense white precipitate, speedily subsiding in heavy clots to the bottom of the vessel, and leaving the liquid almost clear. The precipitate is identified as cyanide of silver by the following properties:—a. It is insoluble in cold nitric acid; but when drained of water, and a sufficient quantity of strong acid is added, it is easily dissolved on boiling. b. It evolves prussic acid when digested in muriatic acid. c. The precipitate, when well dried and heated in a small reduction tube, yields cyanogen gas, which may be burnt at the mouth with a rose-red flame and blue halo. This is a well-marked character, and at once identifies the acid which yielded the precipitate as prussic acid. By this property, the cyanide is eminently dis-
timguished from all the other salts of silver. In the employment of the silver-test for the detection of the vapour of the poison, we place a few drops of the silver solution in a watch-glass, and invert it over another watch-glass containing the suspected poisonous liquid. Cyanide of silver, indicated by the formation of an opaque white film in the solution, is immediately produced, if the acid be only in a moderate state of concentration. One drop of the pharmacopoeial acid (containing less than the 1-50th of a grain) produces speedily a visible effect. When the prussic acid is much diluted, a few minutes are required; and the opaque film begins to show itself at the edges of the silver solution. In this case the action may be accelerated by the heat of the hand.

2. The Iron-Test.—The object of the application of this test is the production of Prussian Blue. We add to a small quantity of the suspected poisonous liquid, a few drops of potash and of a solution of green sulphate of iron. A dirty green or brownish precipitate falls; on shaking this for a few minutes, and then adding diluted muriatic or sulphuric acid, the liquid becomes blue; and Prussian blue, of its well-known colour, unaffected by diluted acids, subsides. If the prussic acid be in small quantity, the liquid is at first yellow, from the salt of iron formed; it then becomes green, but the precipitate ultimately subsides so as to appear of a blue colour in the mass. The same result is obtained by adding the solution of the iron-salt to the potash-solution of the cyanide of silver; and thus, in this way, the two tests may be applied to only one portion of the poison. The iron-test may be employed for the detection of the vapour of prussic acid, by the same method as that described in speaking of the silver-test. For this purpose we place a few drops of caustic potash in a small white saucer, and invert it over the suspected liquid. After a few minutes a drop of solution of green sulphate of iron may be added, and then a drop of diluted muriatic acid, — Prussian blue appears. The recently precipitated mixed oxides of iron with potash, may be placed in the upper vessel with the same results. The silver and the iron-tests may be easily conjoined in testing the same quantity of poison. If the precipitated cyanide of silver, obtained by the addition of nitrate of silver to the suspected liquid, be moistened with strong muriatic acid, and the vapour collected in a watch-glass or saucer, on the plan just described, Prussian blue will be procured, and thus strongly corroborate the action of the silver-test.

3. The Sulphur-Test. — Liebig has proposed the following process for detecting prussic acid as a liquid. (Oesterreichische Med. Wochenschrift, 27 März, 1847, 396.) If a small quantity of hydrosulphate of ammonia (containing a little excess of sulphur) be added to a few drops of the solution of prussic acid, and the mixture be gently warmed, it becomes colourless,
and, on evaporation, leaves sulphocyanate of ammonia — the sulphocyanic acid being indicated by the intense blood-red colour produced on adding to the residue a solution of a persalt of iron: the colour immediately disappears on adding one or two drops of a solution of corrosive sublimate. The intensity of the colour is also destroyed by moderate dilution with water. This process is very delicate, and it therefore requires some care in its application: thus, if the boiling and evaporation be not carried far enough, the persalt of iron will be precipitated black by the undecomposed hydrosulphate of ammonia; and, if the heat be carried too far, the sulphocyanate of ammonia may itself undergo decomposition, and be lost. It will be perceived, too, that it requires a longer time for its application than either the silver or the iron-test. If the prussic acid contains traces of Prussian blue or a salt of iron, it will acquire a dark colour on the addition of hydrosulphate of ammonia.

The great utility of the sulphur-test, however, is in its application to the detection of the minutest portion of prussic acid when in the state of vapour. In this respect it surpasses any other process yet discovered. In order to apply it, we place the diluted prussic acid in a watch-glass, and invert over it another watch-glass, holding in its centre one drop of the hydrosulphate of ammonia. No change apparently takes place in the hydrosulphate; but if the watch-glass be removed after the lapse of from half a minute to ten minutes, according to the quantity and strength of prussic acid present, sulphocyanate of ammonia will be obtained on gently heating the drop of hydrosulphate and evaporating it to dryness. With an acid of from three to five per cent, the action is completed in ten seconds. The addition of one drop of persulphate of iron to the dried residue brings out the blood-red colour instantly, which is intense in proportion to the quantity of sulphocyanate present. Such is the simple method of employing the test. When the prussic acid is excessively diluted, the warmth of the hand may serve to expedite the evolution of the vapour. I have elsewhere made some remarks on the application of this process for the detection of prussic acid. (See Med. Gaz. Vol. xxxix. p. 765.)

In detecting the vapour, the sulphur-test acts, ceteris paribus, more rapidly and more delicately than the silver-test; but the two may be usefully employed together in corroborative of each other. If a suspected liquid, placed in a watch-glass, produce a film on a drop of nitrate of silver, the reaction will be very speedy with the hydrosulphate. The silver-test acts visibly, and therefore serves as a guide: the sulphur-test acts invisibly; for there is no apparent change unless the glass be left so long that the ammonia is spontaneously evaporated, and the sulphur oxidated or deposited.

Prussic Acid in Organic Liquids. Detection by vapour without
distillation.—The organic liquid may be placed in a wide-mouthed bottle, to which a watch-glass has been previously fitted as a cover. The capacity of the bottle may be such as to allow the surface of the liquid to be within one or two inches of the concave surface of the watch-glass. The solution of Nitrate of silver is then used as a trial-test in the way already described. If the 1-200th of a grain of prussic acid be present, and not too largely diluted, it will be detected (at a temperature of 60°) by the drop of nitrate of silver being converted into an opaque white film of cyanide of silver, the chemical change commencing at the margin. We may then substitute for the nitrate of silver the hydrosulphuret of ammonia, and proceed in the manner above described. By this process I have detected prussic acid in the stomach of a person poisoned by it, as late as twelve days after death. After the stomach had been exposed for a few days longer, all traces of the poison had disappeared.

Detection by distillation.—This process was originally suggested by Lassaigne. The organic liquid should be distilled in a water-bath, at 212°, and about one-sixth or one-eighth of the contents of the retort collected in a receiver kept cool by water. The tests may now be applied to the distilled liquid. If the trial-tests indicate that the quantity of poison is small, a solution of nitrate of silver or caustic potash may be placed in the receiver, to fix the acid as it distils over; Prussian blue may then be procured in the way described, or the vapour may be at once absorbed by hydrosulphuret of ammonia in the receiver, and the liquid evaporated to obtain sulphocyanate. Prussic acid has been found in the stomach by distillation, so late as seven days after death, although the odour could not be perceived before distillation. According to a statement made by the late Mr. West, he was able to detect prussic acid, on distillation, by the odour, and the silver and iron tests, twenty-three days after death; although no pains had been taken to insure its preservation, and not more than four-tenths of a grain of anhydrous acid could have originally existed in the contents of the stomach. (Prov. Med. Jour. July 23, 1845.)

In the case of Walter Palmer (Rugeley Inquest, Jan. 1856), the question arose whether, assuming that the deceased had taken just a fatal dose of Scheele's prussic acid, i.e. twenty grains, or about one-third of a teaspoonful,—it was probable that any part of this dose would remain in the stomach four and a half months after death? Dr. Rees and I had examined the stomach, and found no prussic acid. We gave our opinion to the effect that, under the circumstances, the deceased might have taken a fatal dose, and all have disappeared within the time mentioned. Mr. Herapath of Bristol, subsequently to the inquest, circulated a statement implying that he had succeeded in detecting prussic acid after a longer period. Admitting this statement, it amounts
to nothing in the absence of any knowledge of the quantity of poison taken, of the length of time the person survived, the quantity found in the stomach, or the circumstances under which the body or bodies were placed. As a "professed analyst" Mr. Herapath knew that the question was, not whether the poison could be detected in some cases after long periods, but whether any portion of twenty grains of Scheele's acid would be likely to be found in a dead stomach nearly five months after a body had been in the grave! This question he abstained from answering. So volatile is prussic acid, that I have found the vapour to traverse wet and dry bladder in a few minutes. Hence great care should be taken in preserving a stomach supposed to contain this poison.

Detection of prussic acid in the tissues. — Soon after death the poison may be easily detected in the blood, secretions, or any of the soft organs, by placing them in a bottle, and collecting the vapour in the manner already described. This will be found to be far more convenient and satisfactory than the process by distillation. In the case of a dog poisoned by a large dose of prussic acid, Mr. Hicks brought to me the stomach after it had been exposed twenty-four hours, and thoroughly washed under a current of water, and yet the poison was readily detected by placing the whole organ in a bottle, and absorbing the vapour by nitrate of silver. This shows how completely the animal tissues at death are penetrated by prussic acid, and how firmly for a time it is retained by them. The poison has been thus discovered, in experiments on animals, in the blood and in the serous exhalation of the chest.

Oil of Bitter Almonds. Almond Flavour.

Bitter Almonds, when eaten in immoderate quantity, may exert a poisonous action. (See On Poisons; also Ed. Monthly Jour. Oct. 1850, p. 379.)

Symptoms and effects. — A man, aged forty-eight, swallowed two drachms of the ethereal oil of bitter almonds. In a few minutes afterwards, he was found by his servant with his features spasmodically contracted, his eyes fixed, staring, and turned upwards. The chest was expanded convulsively and hurriedly. In twenty minutes he was insensible, the pupils immovable, the breathing slow and stertorous,—the breath having a strong odour of bitter almonds, and the pulse feeble. He died half an hour after he had taken the poison. On inspection, the whole of the body, and the blood which escaped, smelt strongly of bitter almonds; the teeth were fixed, the lips pale, fingers contracted, and the nails blue. The mucous membrane of the stomach and intestines presented an inflammatory redness, and there was turgescence of the brain. The blood, bile, and the muscles, had a deep violet colour. (Ed. Med. and Surg. Jour.
The following case occurred to Mr. Chavasse, of Birmingham:—A druggist swallowed by mistake half an ounce of "almond flavour." In half a minute he fell down in a state of syncope; his face being deadly pale, and his pulse imperceptible. After a few minutes he came to himself, and vomited some undigested food mixed with bile, and strongly impregnated with the odour of bitter almonds. Delirium, with slight convulsions, came on: he then became sensible, and conversed upon his condition; but again gradually relapsed into delirium, his eyes being prominent and brilliant. In a few minutes he again became sensible, and slowly recovered from the effects of the poison. The quantity of "almond flavour" which he had taken was estimated to contain about half a drachm of the essential oil.

A case in which a similar dose proved fatal, occurred to Mr. Phillips, of Coventry, in March, 1853. A woman, aged thirty-nine, swallowed half an ounce of almond flavour (prepared with one drachm of the essential oil to seven drachms of rectified spirit). After swallowing the poison, she seized a water-jug, walked to a tap in the yard, and drew and drank off a large quantity of water. She then went up two flights of stairs, calling for her child, descended one flight to a bed-room, and was heard to fall heavily on the bed. These acts occupied about five minutes. In another five minutes she was seen by Mr. Phillips, who found her perfectly insensible and motionless, pupils moderately dilated and insensible to light, mouth partly open, lips pale, no distortion or spasmodic movement of the features, pulse slightly tremulous, entirely ceasing in a few minutes, breathing slightly stertorous, and taking place at long intervals. She continued in this state for twenty minutes without the least convulsive movement of the body, when she died, i.e., half an hour after taking the poison. There was a strong odour of bitter almonds in the room. On inspection, twenty-four hours after death, there was a strong smell of bitter almonds at the mouth. The vessels of the brain were much congested with dark fluid blood, and the odour of the poison was perceptible in the brain on making a section through it. The lungs were engorged with black blood throughout. The left ventricle of the heart was firmly contracted,—the right cavities were moderately distended. The stomach contained four ounces of a fluid smelling strongly of bitter almonds; its mucous membrane presented a slight inflammatory redness towards the greater end. The intestines were healthy. There was no congestion of the liver, spleen, or kidneys. Mr. Phillips forwarded to me for examination the contents of the stomach, and about two drachms of blood taken from the right auricle of the heart. The contents of the stomach, amounting to about three ounces, were reddish coloured, owing to the presence of a small quantity of blood: they were liquid, and slightly acid. When the examination was made, i.e., five
days after death, they had a slightly aromatic smell; but an experienced person, unacquainted with the facts, could perceive in them no odour of prussic acid or of bitter almonds. Prussic acid was, however, readily detected in the vapour issuing from the liquid by the silver and sulphur tests: and by distillation a quantity of colourless liquid was procured, from which cyanide of silver and Prussian blue were readily obtained. The blood was of a dark red colour. It had separated perfectly into serum and coagulum, like healthy blood. It had no particular odour; and neither before nor after distillation did it yield any indication of the presence of prussic acid. Examined under a microscope, with a power of 300 diameters, the corpuscles were seen of their usual size and shape; they had undergone no physical change by the action of the poison.

Dr. Bull, of Hereford, communicated to me a case in which less than twenty drops of the oil destroyed the life of a woman, aged forty-nine, in half an hour. This poisonous action is owing to the quantity of prussic acid contained in the oil. The proportion varies from five to twelve per cent. [For a case of poisoning by this oil, reported by Mr. Iliff, jun., see Lancet, Dec. 1, 1849, page 575.]

Is the vapour of this oil, or rather of the prussic acid contained in it, sufficient to produce fatal effects? This question was raised in the subjoined case, which occurred in London, in 1838. The deceased, the wife of a publican, had been clearing out a closet, which contained, among other liquors, a bottle of the essential oil of bitter almonds. She was suddenly heard to call out. A servant found her pale and faint, and she complained of sickness. There was a strong odour in the room, and deceased said that the corks of some of the bottles had come out, and the smell had made her feel sick. She was removed to bed, but died before any medical assistance could be obtained. There was no motive for the deceased committing suicide, and it was a subject of inquiry, whether the vapour alone might not have caused death. This question was set at rest by an inspection of the body. Some of the poison was found in the stomach, and there was a very strong odour of bitter almonds in the contents. It was, therefore, clear that the deceased must have swallowed a portion of the poison; whether from motives of curiosity or not, it is impossible to say. The medical witness, in answer to a question, properly stated, that less that a teaspoonful might cause the death of an adult. The vapour may produce giddiness and stupor; but unless long respired, it would not be likely to cause fatal effects. In 1837-38, there were only four cases of poisoning by this oil. It is now a frequent cause of death. This poison is sold to the public, in quantities of not less than a quarter of an ounce, at the rate of five shillings per ounce.
Analysis.—The oil is of a pale yellow colour, and has a strong odour of bitter almonds. It is very heavy, and sinks in distilled water. Treated with strong sulphuric acid, it produces a rich crimson-red colour. By exposure to air, or on addition to water, this colour changes to a yellow. The oil is soluble in alcohol in all proportions. The presence of prussic acid in it is proved by adding to the alcoholic solution a few drops of a solution of green sulphate of iron, followed by potash. On adding diluted hydrochloric or sulphuric acid, Prussian blue remains and is deposited. (See Iron-Test, p. 165, ante.) The powerful odour of the oil is sufficient to reveal its presence even in small quantity.

The liquid called Almond flavour, spirit of almonds, or essence of peach-kernels, contains from half a drachm to one drachm of the essential oil to one ounce of spirit. It is sold, in quantities of not less than a quarter of an ounce, at the rate of one shilling per ounce. The chief use of this liquid is for the purpose of flavouring confectionery. Serious symptoms have in some instances been produced by small quantities of it; and as cooks and confectioners, who use it, are not aware that they are administering prussic acid to their customers, it is possible that accidents may arise from this practice. A flavour is at all times dearly purchased if it depends on even a small dose of poison. Within a recent period, a liquid has been sold for flavouring confectionery under the name of Essence of Jaryonelle Pear. It is a noxious artificial compound made by distilling oil of grain, or fusel oil, with acetate of potash and sulphuric acid. In the Pharmaceutical Journal for November, 1851 (page 214), it is stated that a child which had on two occasions eaten confectionery flavoured with about one drop of the essence of pear, became partially comatose, with livid lips and feeble pulse. The symptoms resembling poisoning, observed in children, may very commonly be referred to the eating of confectionery which is coloured or flavoured with various kinds of poison. Another artificial fruit-essence has been still more recently brought into notice—namely, the “Essence of Ripstone Pippin,” or “oil of apples.” It is procured from a mixture of bichromate of potash, sulphuric acid, and amylc alcohol (Chemical Record, Jan. 17, 1852, p. 44)—all substances of a noxious nature. A compound of impure glycerine and rectified spirit produces an essence having the odour of Pine-apple.

Noyau. Cherry Ratafia.

These liqueurs, which have the smell of bitter almonds, are considered to be poisonous when taken in large doses. The quantity of prussic acid present in them is liable to vary; it may be separated by distillation at a gentle heat, and then tested. I have found that an ounce and a half of good noyau having a
strong odour and flavour, when distilled to two-thirds, yielded scarcely a trace of prussic acid either by the silver or iron test. It had been kept some time in a well-closed bottle. An equal quantity of cherry ratafia, similarly treated, gave no ponderable quantity of Prussian blue. The prussic acid in many of these liqueurs is derived from Cherry, Peach, and Apricot Kernels. A case is reported in the Journal de Chimie Medicale, 1853, page 38, in which a child, two years of age, suffered severely in consequence of having eaten ten or twelve apricot kernels.

**Laurel-water. Cherry-laurel water.**

This is a very weak solution of prussic acid, containing only about one-fourth of a grain per cent. of the strong acid, but it is stated to be more poisonous than this quantity of acid would indicate. (Pereira, Vol. ii. pt. ii. 279.) In some specimens which I procured by distilling the bruised tops and fine shoots of the laurel with water, the odour was powerful; but the proportion of prussic acid present was much smaller than this. The water is a limpid colourless liquid, possessing a strong odour of bitter almonds, and producing, in large doses, the usual effects of poisoning by prussic acid. **Cherry-laurel oil.**—By distillation, the leaves of the plant yield also an essential oil, resembling that of the bitter almond, but much weaker, as it contains on an average less than three per cent. of prussic acid. According to Christison, almost every part of the plant is poisonous, but especially the leaves, flowers, and kernels; the pulp of the cherry is not poisonous. Articles of food are often flavoured with the leaves, and accidents are said to have arisen from this practice.

**Cyanide of Potassium.**

**Symptoms and effects.**—This is a poisonous salt, now much used in the arts of electro-gilding, plating, and photography. It is a solid, sometimes seen crystallised, at others in the form of a white chalky-looking powder. It is without odour until put into water, when it is freely dissolved, forming an alkaline solution, from which prussic acid is abundantly evolved, either by exposure to air, or on the addition of an acid. It acquires a strong smell in a damp atmosphere, and becomes dark-coloured. The cyanide of potassium is used on the continent as a medicine, and a few years since it occasioned the death of a person at St. Malo, under the following circumstances:—A physician prescribed for the deceased rather more than one drachm of the cyanide in two ounces and a half of orange-flower water and syrup; and of this mixture three spoonfuls were to be taken daily. It seems that table-spoonfuls were taken, and the patient died in three quarters of an hour after the first dose. None of the poison was found in the stomach; but a portion of the mixture
from which the dose had been taken, was examined and found to contain cyanide of potassium. A criminal procedure was instituted against the physician, and he was fined and imprisoned. M. Malagni, who gave evidence on the occasion, stated that a dog was killed in a few minutes after taking less than three grains of the cyanide in solution; and that the largest medicinal dose of this substance to a human being was five-sixths of a grain. (Lancet, Jan. 1848.) The mixture in the above case contained about three grains of the cyanide in one dram; therefore, had teaspoonfuls been taken by the deceased, he would still have taken a sufficient quantity to have destroyed life. The medicine had evidently been prescribed by a person totally ignorant of its poisonous properties. Another case occurred at Breslau, in which a man, aged thirty, died in a quarter of an hour under all the symptoms of poisoning by prussic acid, after taking a dose of a mixture containing fifteen grains of cyanide of potassium, which had been prescribed for him by his medical attendant. (Henke, Zeitschrift der S. A. 1843, 7. See also Ann. d’Hyg. 1843, i. 404.)

Cases of poisoning by this agent have been rather frequent of late years. The cyanide of potassium is much used as a solvent for silver, and is largely employed by photographers and coiners; the latter employ it for covering base metal. In its use for photographic purposes it has been productive of some injurious effects by reason of its locally corrosive action on the skin. This may have led to the absorption of a portion. The use of the solution when there were any cuts or abrasions on the hand would be attended with danger. In most cases in which it has been swallowed, the poison has proved so rapidly fatal, that the persons have died before they were seen by a medical practitioner. The symptoms have not, therefore, been frequently observed; but, so far as we can form a judgment, they are identical with those produced by prussic acid. (See Med. Times, Oct. 12, 1850, p. 390; also Nov. 9, 1850, p. 482; and July 12, 1851, p. 41.)

A new use for this substance, also leading to fatal accidents, is recorded in the Registrar-General’s report for October 3, 1857. Three deaths from it are here reported to have occurred among soldiers’ families,—two cases of suicide and one of accident. It appears that they employ it for the purpose of cleaning lace.

Analysis. — The production of Prussian blue by the Iron-test (ante, p. 181) is sufficient to identify this substance in solution. Prussic acid is obtained from it by distillation with an acid; and the vapour-tests may be applied to small portions of the salt moistened with diluted acid in watch-glasses.

It has been supposed that the cyanide of potassium might exist in the state of vapour, and destroy life by its accidental introdus-
tion into the lungs. When this salt is exposed to a damp atmosphere, or is acted upon by acids, hydrocyanic acid freely escapes, and the respiration of this vapour may produce injurious, or even fatal effects. It does not appear probable, however, that the cyanide should itself ever be respired in the state of vapour. In December, 1853, an inquest was held at Elsecar by Mr. Badger, under the following remarkable circumstances:—Three members of a family named Sadler, and a lodger, went to bed in their usual health at about ten o’clock, sleeping in different bedrooms. At seven the following morning they were all found dead. The house in which this accident occurred abutted on one of the blast furnaces of the Elsecar Iron-works; and it was obvious that some noxious vapours from the furnace must have escaped into the rooms through a crack in the house-wall. It was considered by a gentleman who examined the premises, that the noxious agent in this instance was the cyanide of potassium in vapour: but as this salt is not volatile under a white heat,—is only evolved in the lower part of iron furnaces, and cannot be carried far without condensation, it is difficult to conceive how it could exist and spread itself in the form of a respirable vapour through the air of the apartments in which the deceased were sleeping. The more probable explanation, as it appears to me, is, that carbonic oxide or nitrogen from deoxidised air was the agent of destruction in this instance, supposing that no carbonic acid was formed by the combustion of the carbonic oxide. It is inconceivable that a substance which remains fixed at a heat of 1000° and upwards, should be diffused at a distance in the form of vapour through air at common temperatures; and nothing short of its detection in and upon the bodies of the deceased could warrant the admission, that the respiration of this substance in vapour was really the cause of death.

CHAPTER XVIII.

HYOSCYAMUS NIGER.

All the parts of this plant, which is commonly known under the name of Henbane, are poisonous. The seeds produce the most powerful effect, then the roots, and lastly the leaves. The vapour evolved from the fresh-cut leaves has been known to produce vertigo, stupor, and syncope. In small or medicinal
doses, henbane has a narcotic action; but when taken in large
doses, it produces those effects usually assigned to the narcotic-
irritant class.

**Symptoms and appearances.** — The best summary of these is
given by Wibmer (Arzneimittel, Art. Hyoscyamus Niger). When
the dose is not sufficient to destroy life, the symptoms are,
— general excitement, fulness of the pulse, flushing of the face,
weight in the head, giddiness, loss of power and tremulous
motion of the limbs, somnolency, dilatation of the pupils, double
vision, nausea, and vomiting. After a time these symptoms pass
off, leaving the individual merely languid. When a large quan-
tity of the root or leaves has been eaten,—an accident which has
occurred from the plant having been mistaken for other vege-
tables,—then other and more serious effects are manifested. In
addition to the above symptoms in an aggravated form, there
will be loss or incoherency of speech, delirium, confusion of
thought, insensibility, coma, and, sometimes, a state resembling
insanity (see Med. Gaz. vol. xlvi. p. 640); the pupils are dilated,
and insensible to light; there is coldness of the surface, cold
perspiration, loss of power in the legs, alternating with spasms;
rigidity, and convulsive movements of the muscles; the pulse
small, frequent, and irregular; the respiration deep and labo-
rious. Occasionally there is nausea, with vomiting and purg-
ing. Death takes place in a few hours or days, according to
the severity of the symptoms. The special effect of this poisonous
plant is manifested in its tendency to produce a general paralysis
of the nervous system. There are other varieties of hyoscyamus
which are also poisonous.

**Lactuca.**

The two species of lettuce known under the names of *Lactuca*
Sativa (garden lettuce) and Virosa (strong-scented lettuce), con-
tain a principle which is possessed of feeble narcotic properties.
Orfila has found that the extract prepared by evaporation at a
low temperature acts upon the brain and nervous system of
animals, although very large doses were required for the pro-
duction of narcotic effects. There is no record of these plants
having exerted a poisonous action in the human subject. The
inspissated juice of the two varieties of lettuce is well known
under the name of lactucarium or lettuce-opium. (See Pereira,
Vol. ii. pt. ii. p. 36.)

**Solanum.**

There are two species of this plant—the Solanum Dulcamara,
Bitter-sweet or Woody-nightshade, which has a purple flower and
bears red berries; and the Solanum Nigrum, or Garden-night-
shade, with a white flower and black berries. Dunal gave to a dog
four ounces of the aqueous extract, and, in another experiment, 180 ripe berries of the Dulcamara, without any ill effects resulting. On the other hand, Floyer states that thirty of the berries killed a dog in three hours. (Wibmer, op. cit. Solanum.) These differences may perhaps be reconciled by supposing that the active principle Solania, on which the poisonous properties of both species depend, varies in proportion at different seasons of the year. In one instance, a decoction of the Dulcamara is said to have produced in a man dimness of sight, giddiness, and trembling of the limbs—symptoms which soon disappeared under slight treatment. (For a case of poisoning by the decoction, see Med. Gaz. xlvi. 548.) Orfila found that the extract of Solanum Nigrum had a very feeble effect as a poison; and the fatal cases reported to have been caused by it are perhaps properly referable to belladonna, for which it may have been mistaken. The single death from Dulcamara reported in the Registration returns for 1840 may have been due to a mistake of this kind.

**Camphor.**

In the few cases of poisoning by camphor which have been observed and recorded, its effects were somewhat different, although both in man and animals they were referable to an impression on the brain and nervous system.

**Symptoms and effects.**—The following case is reported by Mr. Hallet, of Axminster:—A woman swallowed in the morning about a scruple of camphor dissolved in rectified spirits of wine and mixed with tincture of myrrh. In half an hour she was suddenly seized with languor, giddiness, occasional loss of sight, delirium, numbness, tingling and coldness of the arms and legs, as well as loss of muscular power, so that she could hardly walk. The pulse was quick and respiration difficult, but she suffered no pain in any part. On the administration of an emetic, she vomited a yellowish liquid, smelling strongly of camphor. In the evening the symptoms were much diminished, but she had slight convulsive fits during the night. The next day she was convalescent; the difficulty of breathing, however, continued more or less for several weeks. The dose did not probably exceed twenty grains: this is the smallest dose of camphor which appears to have been attended with serious symptoms. In a case which occurred to Wendt, of Breslau, eight scruples dissolved in spirits were swallowed by a drunkard. The symptoms were giddiness, dimness of sight, delirium, and burning pain in the stomach. There was no vomiting; the man recovered. In another, reported by Mr. Stookes, a woman swallowed half an ounce of camphor dissolved in oil. In two hours she was delirious; her face pale; pupils dilated; hands and feet cold; pulse 120. There was neither pain, vomiting (except as the result of emetics), nor purging. She recovered in a few hours.
Times, June 10, 1848, p. 88.) These and other cases show that camphor cannot be regarded as an active poison. (Wibmer, op. cit. iii, 212.) In Orfila's experiments on animals, the mucous membrane of the stomach was found inflamed (ii. 493).

In three cases reported by Dr. Schaaf, the symptoms caused by camphor were those of a narcotico-irritant poison. A woman gave about thirty grains (half a teaspoonful) of powdered camphor to each of her three children as a vermifuge. Two of the children were respectively of the ages of three and five years, the third was an infant aged eighteen months. The first symptoms were paleness of the face, with a fixed and stupid look. Delirium followed, with a sense of burning in the throat, and great thirst. Vomiting, purging, and convulsions supervened, and in one child the convulsions were most violent. The two elder children, after suffering thus for three hours, fell into a comatose sleep, and on waking the symptoms passed off. The infant died in seven hours, not having manifested any return of consciousness from the first occurrence of convulsions. (Med. Gaz. xlvii. p. 219.)

In this Journal the dose is erroneously stated to be 180 grains. For a report of the case see Journal de Chimie Médicale, 1830, p. 507.) The severity of the symptoms is fully explained by the large quantity administered and the age of the children. In a dose of one drachm given in a oyster, camphor produced alarming symptoms. (Med. Gaz. xlviii. 552.)

Alcohol.

Symptoms.—A large quantity of spirit has been known to destroy life speedily, although such a case is rare. Orfila mentions an instance in which a man died immediately from the effects of a large dose of brandy. (Op. cit. ii. 528.) In general the symptoms come on in the course of a few minutes. There is confusion of thought, with inability to stand or walk, a tottering gait, and giddiness, followed by coma. Should the individual recover from this state, vomiting and sickness supervene. This form of poisoning presents some singular anomalies:—thus the insensibility may come on suddenly after a certain period. Dr. Christison met with a case in which the individual fell suddenly into a deep stupor some time after he had swallowed sixteen ounces of whiskey; there were none of the usual premonitory symptoms. In another instance a person will apparently recover from the first effects, then suddenly become insensible, and die convulsed. Convulsions are, however, by no means a necessary attendant upon poisoning by alcohol. Orfila makes their absence a ground of diagnosis between poisoning by alcohol and opium. (Op. cit. ii. 530.) Dr. Ogston observed them only twice out of many cases, and the subjects in these instances were young. In poisoning by alcohol, the supervision of the symptoms is not commonly so rapid as to prevent an individual
from performing locomotion or certain acts of volition. The more concentrated the alcohol, the more rapidly are the symptoms induced, and they are then more severe in their character. Diluted alcohol generally produces the stage of excitement before stupor, while in the action of concentrated alcohol there may be profound coma in a few minutes. This appears to indicate an action by sympathy on the nervous system, as the diluted alcohol is in a condition most favourable to absorption.

A person who has taken a large dose of alcohol, or alcoholic liquid, may temporarily recover to a certain extent, but subsequently die from the secondary effects of the poison on the brain and other organs. In general, in alcoholic poisoning the pupil is widely dilated. Its power of contracting is a favourable sign. (See case in Lancet, Jan. 27, 1855, p. 89.)

Alcohol may act as a poison by its vapour. If the concentrated vapour be respired, it will produce the usual effects of intoxication. It is generally known that persons who have been for the first time employed in bottling spirits are easily intoxicated by the alcoholic vapour. There is a case on record in which a child two years of age was thrown into an apoplectic stupor by the alcoholic vapour of Eau de Cologne. In this way a child might be destroyed, and no trace of the poison be found in the stomach.

Appearances.—In respect to appearances in the body, the stomach has been found inflamed—the mucous membrane having been in one case of a bright red, and in another of a dark reddish-brown colour. When death has taken place rapidly, there will be a strong odour of spirits in the contents; but this may not be perceived if many hours have elapsed before the inspection is made. The brain is found congested, and in some instances there is an effusion of blood or serum beneath the membranes. In a case observed by Dr. Geoghegan, in which a pint of spirits had been taken, and proved fatal in eight hours, black extravasation was found on the mucous membrane of the stomach; but no trace of alcohol could be detected in the contents. (Dub. Med. Press, i. 293.)

Ether.

Symptoms and appearances.—The effects produced on the system by the administration of Sulphuric ether or any other form of ether, are not unlike those occasioned by alcohol. Orfila found that about half an ounce of sulphuric ether administered to a dog caused, in a few minutes, a disposition to vomit. This was followed by giddiness, and, in ten minutes, by an entire loss of power in the muscles. Respiration was painful and hurried, but there were no convulsions. After a slight abatement in the symptoms, the dog fell into a state of insensibility, and died in three hours. The whole of the mucous membrane of the stomach
was of a blackish-red colour, and, with the other coats, intensely inflamed. There was slight inflammation in the duodenum; but the rest of the alimentary canal was in a healthy condition. The heart contained black blood partly coagulated: the lungs were gorged with fluid blood. (Op. cit. ii. 531.)

Very little is known concerning the action of large doses of liquid ether taken into the stomach. It has, in moderate doses, a hot burning taste, and produces, during swallowing, a sense of constriction in the throat. It causes, like alcohol, great excitement and exhilaration, with, subsequently, intoxication; but persons may become habituated to it; and thus, after a time, it may be taken in large doses with comparative impunity. The medicinal dose is from half a drachm to two drachms. Dr. Buchanan has known seven drachms of it taken at once: it produced, at the pit of the stomach, a most uneasy sensation of heat and pain, which only the callous stomach of a dram-drinker could withstand. (Med. Gaz. xxxix. 715.) In 1845, a young man was brought before one of the London Police-magistrates in a stupified state; to those present he appeared to be intoxicated. It was proved in evidence that he was in the habit of taking ether, and that he was then labouring under its effects. It appeared that he frequented the shops of druggists, and swallowed this liquid in large doses. There is no instance reported of ether having caused death when taken in the liquid form: but it has never been swallowed at once in the same excessive doses as alcohol. It does not admit of dilution with water to the same degree as alcohol, and therefore it acts, ceteris paribus, as a more violent local irritant. It requires ten parts of water to dissolve one of ether: hence, unless, as Dr. Buchanan has remarked, the water be in very large proportion, it does not render the ether palatable to most persons. It is at present impossible to give any precise opinion respecting the smallest quantity of this liquid which would destroy the life of an adult. Hoffmann’s Liquor is a mixture of alcohol and ether.

Ether vapour.—The vapour of ether, when respired, may act as a cerebral poison. Several cases in which it has thus proved fatal, when it has been administered for the purpose of producing insensibility during surgical operations, are recorded, and for an account of these, as well as of poisoning by the vapour generally, I must refer to the separate work On Poisons.

Chloroform.

Liquid chloroform.—This liquid, when taken in a large dose, appears to affect the system like alcohol; but as a liquid it cannot be regarded as an active poison. I have elsewhere recorded a case communicated to me by Mr. Jackson, of Sheffield, in which a man swallowed four ounces of chloroform. He was able to walk for a considerable distance after taking this dose, but he
subsequently fell into a state of coma—the pupils were dilated, the breathing stertorous, the skin cold, the pulse imperceptible, and there were general convulsions. He recovered in five days (Med. Gaz. vol. xlvii. p. 675.) I am indebted to Mr. Thursefield, of Broseley, Salop, for another case which proved fatal in March, 1854. A boy, nat. 4, was brought to him by his father in a state of total insensibility. It appears that he had swallowed a drachm of chloroform, and soon afterwards laid his head on his mother’s lap and lost all consciousness. Mr. Thursefield saw him about twenty minutes afterwards. He was then insensible, cold, and pulseless. Mustard plasters were applied to the legs; they acted well, but produced no impression on his sensibility. His breathing varied; it was sometimes natural, at others stertorous. He became warmer, his pulse full and regular; and he continued three hours in this state, when he died quite calmly without a struggle, in spite of every effort made for his recovery.

Chloroform vapour. Symptoms. — The symptoms which the vapour of chloroform produces are very similar to those produced by the vapour of ether; but the individual passes much more rapidly into a state of insensibility with stertorous breathing. From being at first excited, he becomes motionless,—the pupils widely dilated,—the sphincters lose their contractile power,—the face is pale, the lips are congested, the breathing is slow, the surface cold, and the pulse gradually sinks. There is an entire loss of sensibility. The sinking of the pulse in some cases is so rapid as to expose the patient to death by syncope (see case, Med. Gaz. xl. 1036). In some instances violent convulsions have supervened, even when the dose has been only from half a drachm to a drachm. These effects may be occasionally aggravated by idiosyncrasy, or by latent organic disease. The fatal effects of the vapour are likely to be manifested when it is breathed rapidly and unmixed with air. There is no doubt that in a concentrated state it is a powerful poison. It is absorbed into the blood, which it darkens, as in asphyxia, and is circulated throughout the system. The blood is probably directly poisoned by it.

Appearances. — In a case reported by Dr. Meggison, a girl, nat. 15, had the vapour administered to her on a warm cloth. The quantity of chloroform used was about one drachm. In about half a minute, she became insensible—the lips were suddenly blanched, and it was observed that one arm was rigid. The respiration was quick, but there was no stertor. The patient suddenly spluttered at the mouth, as if in an epileptic fit. Attempts were made to revive her, but she was dead in from two to three minutes after commencing the inhalation. On inspection, the lungs were found greatly congested. There was a bloody froth in the bronchi, mixed with mucus:—
the epiglottis was reddened. The brain and its membranes were more congested than usual, and the ventricles contained more than the usual quantity of serum. The abdominal viscera were also highly congested. (Med. Gaz. xli. 250-254.) These appearances correspond to those observed in the action of the vapour on animals. In a case reported by Dr. Jamieson, in which the quantity inhaled was probably three or four drachms, the appearances of general congestion were very similar (Med. Gaz. xli. p. 318); it was remarked that the mass of blood was darker than usual, and that it was fluid and unusually thin. The muscles were also dark-coloured.

As in cases of alcoholic poisoning, death may take place from secondary causes after slight recovery. A gentleman, age 49, had the vapour administered to him, for the purposes of a surgical operation, to the amount of six drachms. The state of insensibility was continued during eight minutes. Consciousness was completely restored after the operation, and the patient conversed freely. In the course of the day he experienced unpleasant sensations in his head, and he passed a restless night. The next morning the pulse was 100, and rather full, and he seemed drowsy. In the afternoon he became comatose, and in spite of treatment he died about forty hours after the administration of the chloroform. On inspection twelve hours after death, there was great congestion of the brain, with some effusion of serum. It is probable that in this case death was accelerated, if not caused, by chloroform. (Kesteven’s Quarterly Report on Toxicology, Med.-Chir. Rev., April 1854, p. 382. Case by Dr. King, in Ed. Med. and Surg. Journal, Jan. 1854.) Another case of death subsequent to apparent recovery has been reported by Mr. Lane, Surgeon to the Lock Hospital. (Med. Times and Gaz., June 3, 1854, p. 572.) The patient was a youth, age 18. Chloroform was administered for the purpose of preventing pain during an operation. About two drachms were inhaled through a simple mouth-piece, by which the nostrils were left uncovered. After about six minutes insensibility appeared to be coming on; the pulse was then of a good volume. There was nothing to indicate impending danger, when, after a few more inhalations, the pulse suddenly failed, became quite imperceptible, and the countenance assumed a pale and leaden hue. The inhalations were stopped, and attempts at resuscitation were made. The pulse returned, as well as spontaneous breathing, and the countenance assumed a slight flush. In ten minutes these favourable symptoms ceased, the countenance became death-like, and the patient sank rapidly. On inspection the next day, there was great venous congestion in the brain and lungs. The heart was slightly enlarged, and the walls of the ventricles were thinned. The blood was of a dark colour, and universally fluid. There appears to have been nothing in the condition of this patient to account for the fatal
POISONING BY CHLOROFORM. 

199

effects of the vapour. (See also L'Union Médicale, Sept. 3. 1857, No. 106.)

Numerous fatal cases from the effects of chloroform vapour have been reported in various medical periodicals. The symptoms and appearances have varied but little from those above described. As it would be impossible within the limits of this work to give any detailed account of the cases, I must refer the reader for additional information on the effects produced by this powerful agent, to the accurate reports of a few selected cases. (See Med. Times and Gazette, Oct. 9, 1853, p. 361; April 9, 1853, p. 369; August 13, 1853, p. 173; Oct. 15, 1853, p. 407; Oct. 22, 1853, p. 432; Oct. 29, 1853, p. 461; Nov. 26, 1853, p. 562; Lancet, June 4, 1853, p. 523; Oct. 29, 1853, p. 410; Edinburgh Monthly Journal, April, 1850, p. 377. See also communications by Dr. Snow, to the London Journal of Medicine, April, May, and June, 1852; and Association Med. Jour., Feb. 11, 1853, p. 131.) These cases are well calculated to show that even in the hands of experienced persons, and where all reasonable precautions are taken, chloroform vapour may in a sudden and unexpected manner exert a fatal influence by suspending (paralysing) the action of the heart, or disturbing the functions of the brain and lungs. According to Dr. Snow, the recorded cases of death from the inhalation of the vapour, up to 1853, amounted to thirty-seven. (Med. Times and Gazette, Dec. 24, 1853, p. 665.) Fatal cases still occasionally present themselves even when the best precautions are used, and there are probably some the details of which do not come before the public or profession. The result of experience is, that in certain morbid conditions of the heart and brain the inhalation of this vapour even in ordinary doses is likely to prove fatal; and we further learn, from the examination of the fatal cases, that the morbid states of these organs which thus render the use of chloroform vapour dangerous, are not always ascertainable during life.

The vapour of chloroform being more volatile than that of ether, would not be so readily detected in the body by the smell. In Dr. Jamieson’s case, the blood had no odour, but the bloody fluids yielded on distillation a small quantity of a volatile liquid, which had a strong chloroform smell. A process for detecting chloroform in the tissues has been suggested, but as it rather detects chlorine, hydrochloric acid or a chloride, and not chloroform, it is unnecessary here to describe it. In consequence of the power possessed by this vapour of rendering persons insensible and incapable of offering resistance in assaults with intent to commit rape and other felonies, the using of it for such a purpose has been made a felony by Act of Parliament (14 and 15 Vict. ch. 19, s. 3).
AMYLINE.

The vapour of this new anaesthetic agent has been introduced by Dr. Snow as a substitute for the vapour of chloroform. It has been found to produce a loss of sensibility without causing complete coma or stupor. Its use has already led to at least two deaths; and on the whole, it does not appear to be so safe an agent as chloroform vapour for surgical purposes. The only appearance met with in one case was an emphysematous state of the lungs or excessive dilatation of the air-cells (Med. Times and Gazette, April 14 and 18, 1857, pp. 332, 381); and in the other, a distension of the right cavities of the heart with dark fluid blood. There was no congestion of the brain and no smell of amylene perceptible in the body. (Med. Times and Gazette, Aug. 8, 1857, p. 133.)
SPINAL AND CEREBRO-SPINAL POISONS.

CHAPTER XIX.

These poisons treated in this section are derived from the vegetable kingdom. Their effects on the body are of a mixed character, since in the state of vegetable, as leaves, seeds or roots, both the brain and alimentary canal are liable to be affected by them. For the most part they contain an alkaloid or principle to which their poisonous action is due.

In order to prove fatal in the vegetable state, they require to be exhibited commonly in large doses. The symptoms in most cases appear in from half an hour to an hour; but sometimes they may be delayed for many hours. This has been especially noticed with regard to poisonous mushrooms. The symptoms usually observed are giddiness, coma, delirium, paralysis and convulsions; such, at least, are the effects resulting from Monkshood (Aconite) and deadly Nightshade (Belladonna). These vegetable poisons have in general a strong and well-marked taste, so that they cannot be criminally administered without suspicion being excited, or without detection. Murder by monkshood has, however, been accomplished by the criminal substitution of the leaves of this plant for other vegetables at a meal.

The Strychnos tribe, including Nux Vomica, has a specific action on the spinal marrow, producing tetanus and convulsions, but rarely coma or delirium. Hence the seeds of these plants, as well as their alkaloids, strychnia and brucia, may be regarded as true spinal poisons. Squills and foxglove (Digitalis) produce symptoms of narcotism, i.e. they affect the brain; but these symptoms are commonly preceded by vomiting, with violent pain in the stomach and bowels, indicative of an irritant action.

Thus, then, there is great variety in the effects produced by
this class of poisons, and the same may be said of the appearances in the bodies of those who have been killed by them. In some instances, when the root or leaves have been taken, or a decoction of them, the stomach and intestines are inflamed; in others not. When the person has died under cerebral symptoms, traces of congestion of the brain are occasionally found; but instances of fatal poisoning by these vegetable substances are so rare, that we have yet much to learn respecting the appearances which they produce.

**Nux Vomica. Strychnia.**

**Symptoms.**—Nux Vomica, in powder, is a poison which is frequently taken by suicides. Its intensely bitter taste in a quantity far from dangerous to life renders it difficult to administer it unknowingly. With respect to Strychnia, it has acquired, within the last few years, great notoriety as a poison. It has an intensely bitter taste when dissolved, but when administered in the form of pills, this of course would not be perceived. At a variable interval, after taking either nux vomica or strychnia, the patient experiences a sense of impending suffocation. There are twitchings and jerks of the head and limbs,—a shuddering or trembling of the whole frame. Tetanic convulsions then commence suddenly with great violence, and nearly all the muscles of the body are simultaneously affected. The limbs are stretched out, the hands clenched—the head, after some convulsive jerks, is bent backwards, the whole body is as stiff as a board, and assumes, by increase of the convulsions, a bow-like form (opesthotonos), being arched in the back and resting on the head and heels. The head is firmly bent backwards, and the soles of the feet are incurvated or arched and everted. The abdomen is hard and tense—the chest spasmodically fixed—so that respiration appears to be arrested—the face assumes a dusky or congested appearance, with a drawn and anxious aspect, the eyeballs prominent and staring, and the lips are livid. The intellect is clear, and the sufferings, during this violent spasm of the voluntary muscles, are severe. The patient in vain seeks for relief in gasping for air and in requiring to be turned over, moved or held. With respect to the muscles of the lower jaw—these, which are the first to be affected in tetanus from disease, are generally the last to be affected by the poison. The jaw is not primarily attacked, and is not always fixed during the paroxysm. The patient can frequently speak and swallow. In some cases of poisoning by nux vomica the jaw has been fixed by muscular spasm; but, unlike the lock-jaw of disease, this has come on suddenly in full intensity, with tetanic spasms in other parts, and there have been intermissions which are not witnessed in the tetanus of disease. The sudden and universal convolution affecting the voluntary muscles has sometimes been so violent that the patient
has been jerked off the bed. After an interval of half a minute to one or two minutes, the convulsions subside, there is an intermission — the patient feels exhausted and is sometimes bathed with perspiration. It has been noticed in some of these cases that the pupils during the paroxysm were dilated, while in the intermission they were contracted. Slight causes, such as the attempt to move, or a sudden disturbance, will frequently bring on a recurrence of the convulsions. In cases likely to prove fatal, they rapidly succeed each other and increase in severity and duration until at length the patient dies exhausted. The tetanic symptoms produced by strychnia, when once clearly established, progress rapidly to death or recovery. The duration of the case, when the symptoms have set in, is reckoned by minutes, while in the tetanus of disease when fatal, it is reckoned by hours, days, and even weeks. As a general statement of the course of these cases of poisoning, within two hours from the commencement of the symptoms the person either dies or recovers, according to the severity of the paroxysms and the strength of his constitution.

The time at which the symptoms commence appears from the recorded cases to be subject to great variation. In poisoning by Nux Vomica the symptoms are generally more slow in appearing than in poisoning by strychnia. Until they set in suddenly, the patient is capable of walking, talking, and going through his or her usual occupations. On an average in poisoning by strychnia the symptoms appear in from five to twenty minutes. In two cases, at least an hour has elapsed. (Lancet, August 31, 1850. On Poisoning by Strychnia, 1856, p. 139.) In a case which occurred to Drs. Lawrie and Cowan in June 1853, an hour and a half elapsed. The longest interval recorded was in a case which occurred to Dr. Anderson in 1848, in which two hours and a half elapsed before the appearance of symptoms. (Poisoning by Strychnia, p. 42.) In spite of these facts, an attempt was made in the medical defence of Palmer to mislead the jury by the assertion that an interval of an hour and a quarter in the case of Cook rendered it impossible that the symptoms could have been caused by strychnia! (Reg. v. Palmer, C.C.C., May 1856.) This was the substance of the evidence given by Mr. Nunneley and Dr. Lethaby, from their experiments on animals. They either did not know, or wholly ignored, facts regarding the operation of the poison on the human body, which bore immediately and practically on the question at issue. Had the Court and Jury believed and acted upon the "animal" experience of these witnesses, a great criminal would have owed his acquittal to evidence inconsistent with well-known facts.

Appearances after death.—The body is commonly observed to be relaxed at the time of death, but speedily stiffens and retains
an unusual rigidity for a long period. In the case of the unfortunate John Parsons Cook, who was poisoned by his professional friend William Palmer, the rigidity of the body and limbs was still well marked on exhumation, after two months' interment. The hands are clenched,—and the feet arched, or turned inwards. Among the internal appearances are—congestion of the membranes and substance of the brain,—as also of the upper part of the spinal marrow—congestion of the lungs—the heart is contracted and empty; but its right cavities in other instances distended with liquid blood. The blood has been found black and liquid throughout the body. The mucous membrane of the stomach has occasionally presented patches of congestion, probably depending on extraneous causes; since in other instances the stomach and intestines have been found quite healthy.

At the trial of Palmer, emptiness of the heart in the case of Cook, was set down as an indication that strychnia was not the cause of death; and thus a theory of death from angina pectoris, or some "latent and undiscoverable disease of the nervous system," was set in. This assumption was based on Mr. Nunneley's observations on sixty animals, including dogs, cats, rats, mice, guinea-pigs, rabbits, frogs, and toads, in which he states the right side of the heart was always full of blood. Dr. Letheby supported this view by swearing that he had destroyed "some dozens" of animals by strychnia, and the heart was always full. Giving these gentlemen credit for swearing firmly to that which was within their own knowledge, in respect to dogs, cats, mice, &c., it is still a fact, as these witnesses might have known by proper research, that it is not in accordance with experience on the human body. Out of ten inspections in poisoning by strychnia, in human subjects, the heart has been found either empty or deficient of blood in six! To these, two other cases may be added, in which the cavities of this organ were found empty. (See Guy's Hospital Reports, October 1856. Poisoning by Strychnia.) This should convey a caution to lawyers in trusting to "animal" experience, or to the statements of witnesses who rely upon what they have seen in animals, in preference to facts actually derived from an examination of the dead human body. This assumed criterion of death from strychnia, namely, fulness of the heart, which the counsel for the defence was instructed to pass off to the jury as a settled point in medicine, was in direct conflict with evidence open to his own medical witnesses in actually recorded cases!

Of the appearances produced in poisoning by strychnia, there are none which can be considered strictly characteristic. Congestion of the membranes of the brain and spinal marrow is probably the most common. With regard to the state of the heart and lungs, their condition as to fulness or emptiness must
depend rather on the mode of dying, than on the actual cause producing death.

Quantity required to destroy life.—The sixteenth part of a grain of strychnia killed a child between two and three years of age in four hours. In two cases of adults, in each of which a quarter of a grain had been taken by mistake, the patients only recovered under early treatment. (Lancet, July 26, 1836, pp. 107, 117.) The smallest fatal dose in an adult was in the case of Dr. Warner. Half a grain of the sulphate of strychnia here destroyed life (on Poisoning by Strychnia, pp. 138, 139). There are at least three instances recorded in which persons have recovered after taking one grain, and in one instance a person is said to have recovered from a dose of seven grains (Medical Gazette, Vol. xli, p. 305). These, however, must be regarded as exceptional cases. A fatal dose of strychnia for an adult may be assigned at from half a grain to two grains.

With respect to nux vomica, three grains of the alcoholic extract have destroyed life. The smallest fatal dose of the powder was in a case reported by Hoffmann, and quoted by Christison (p. 901), also by Traill (Outlines, p. 137). Thirty grains of the powder, given in two doses of fifteen grains each, proved fatal. The poison was given by mistake to a patient labouring under quartan fever. This is about equivalent to the weight of one full-sized seed. This question became of some importance in the case of Reg. v. Wren (Winchester Spring Ass., 1851). The prisoner was convicted of an attempt to administer this poison in milk; the quantity separated from the milk amounted to forty-seven grains. The intense bitterness which the nux vomica gave to the milk led to detection, and this would, in general, be a bar to the criminal administration of this poison, except in the form of pills.

Period at which death takes place.—In fatal cases death generally takes place within two hours after the taking of the strychnia. One of the most rapidly fatal cases recorded is that of Dr. Warner. The symptoms commenced in five minutes, and he was dead in twenty minutes. In the case of Cook, the symptoms commenced in an hour and a quarter, and he died in twenty minutes. One of the longest cases for duration was communicated to me by Mr. Wilkins. The deceased, an adult, died in six hours from a dose of three grains of strychnia. (Guy’s Hosp. Reports, Oct. 1857, p. 483.) In poisoning by nux vomica, death usually occurs within two hours; but Dr. Christison mentions a case in which a man died in fifteen minutes after taking a dose (p. 898). This is probably the shortest period known. There are several instances of recovery on record, even after large doses. Mr. Iliff has reported a case in which a female recovered after taking two drachms of this poison. (Lancet, Dec. 15, 1849.)
Chemical analysis.—*Nux vomica* is well known as a flat round kernel, about the size of a shilling, with radiating silky fibres, slightly raised in the centre. It is of a light brown colour, and covered with a fine silky down. It is very hard, brittle, tough, and difficult to pulverise. The powder is of a grey brown colour, like that of liquorice: it is sometimes met with in a coarsely rasped state: it has an intensely bitter taste. It yields to water and alcohol.—*strychnia*, *brucia*, *igasuric* or *strychnic* acid, and some common vegetable principles. Heated on platina foil, it burns with a smoky flame. Nitric acid turns it of a dark orange-red colour, which is destroyed by chloride of tin. In one case of poisoning by this substance (Reg. v. Wren) I found a quantity of guaiacum powder mixed with the *nux vomica*. This so completely changed the action of nitric acid as in the first instance to create some difficulty in identifying the substance. The analyst must be prepared for these adulterations.

The aqueous infusion or decoction is reddened by nitric acid, and is freely precipitated by tincture of galls. Persulphate of iron gives it an olive-green tint. These properties are sufficient to distinguish it from various medicinal powders which it resembles. The fine silky fibres which cover the surface of the kernel may be identified by the microscope. The powder, owing to its indigestible nature, and the rapidity with which it causes death, will generally be found in the stomach and bowels. If a sufficient portion should remain in the body, it may be collected, and *strychnia* extracted from it. The quantity of the alkaloid contained in it is, however, very small. It amounts to a half to one per cent.

*Strophanthia.*—This alkaloid crystallizes from its alcoholic solution in lengthened octahedra and in prisms of a peculiar form, some of which cross each other at an angle of 60°. 1. It is white, of an intensely bitter taste, even when it forms only 1-30,000th part of a solution. 2. When heated on platina, it melts and burns like a resin, with a black smoky flame. 3. It is not perceptibly dissolved by water, and it requires 7000 parts for its solution. 4. It is easily dissolved by acids, and is precipitated from the concentrated solutions by potash, in which it is insoluble. 5. Strong nitric acid impairs to it a red colour, owing to the presence of brucia. 6. Sulphuric acid produces no apparent change: but when to the mixture a small crystal of bichromate of potash, of ferricyanide of potassium, or a small quantity of black oxide of manganese is added, a series of beautiful purple and violet colours appears, which repass rapidly to a light red tint.

In organic mixtures, the process of *Stroas* is generally preferred for the separation of this poison. The principle of its operation consists in dissolving the *strychnia* by rectified spirit
mixed with a vegetable acid (tartaric, oxalic, or acetic). The acid solution of strychnia is concentrated at a low temperature, the acid is then neutralised by potash or its carbonate, and the mixture shaken with its volume of ether, which is found to dissolve the strychnia set free by the alkali. From the ethereal solution, it is obtained crystalline by spontaneous evaporation. For the details of this process see On Poisons.

**Colchicum. (Meadow Saffron.) Colchicina. White Hellebore. Veratrum.**

The roots and seeds of these plants, and the leaves and flowers of colchicum, exert a violent action on the human subject, chiefly manifested by symptoms of irritation in the alimentary canal. With a burning pain in the throat and esophagus, there have been violent vomiting and purging, and death in the course of some hours. After death the stomach has been found inflamed, but not in all instances. In November 1839, a gentleman swallowed by mistake one ounce and a half of wine of colchicum. He was immediately seized with severe pain in the abdomen; other symptoms of irritation came on, and he died in seven hours. There was no examination of the body. In another instance in which an ounce was taken, death occurred in thirty-nine hours. (Schneider’s Annales, i. 232.) In a well-marked case of poisoning by the wine of colchicum, reported by Mr. Feraday, two ounces were taken. The symptoms did not come on for an hour and a half; there was then copious vomiting of a yellow fluid, severe pain with great tenderness in the abdomen, violent straining, and thirst. The patient died in forty-eight hours, without manifesting any sign of cerebral disturbance. The chief morbid appearance was a patch of redness in the mucous membrane of the stomach, near the cardiac orifice; the intestines were slightly inflamed. In another case, in which an ounce and a half of the tincture was taken, and death ensued in forty-eight hours, no morbid appearances were found.

In March 1855, five patients were poisoned at the Toulon Hospital, owing to their having taken by mistake two ounces of Colchicum wine in place of bark wine. Three died in nineteen hours, and two in twenty-six hours. Symptoms did not come on until after the lapse of two hours. They were ushered in by burning colicky pains in the stomach, thirst, constant vomiting, and frequent purging of a serous liquid. There were no cerebral symptoms. The poison acted as a pure irritant. The principal appearances were softening and redness of the mucous membrane of the stomach, with congestion of the liver and spleen. (L’Union Médicale, March 27, 1855.) In one instance a person recovered after swallowing an ounce of the tincture. There were cramps in the limbs and twitchings in the
tendons. (L'Union Méd. Aug. 24, 1848.) A case of poisoning
by the medicinal administration of colchicum has been com-
municated to me by Mr. Mann, of Bartholomew Close. Three
and a half drachms of the wine of colchicum were taken in divided
doses, and caused death on the fourth day. There was no in-
fammation of the mucous membrane, but simply extravasation
of blood in the mucous follicles.

Seeds.—A man, aged fifty-two, took a decoction, made with a
tablespoonful of colchicum seeds to a pint and a half of water.
He was seized with vomiting and purging, continuing incessantly
until death, which took place in about thirty-six hours. The
only appearance of note was that the stomach had a violet or
purple hue. Two cases of death from the fresh seeds are re-
ported in the Journal de Chimie Méd. 1853, p. 421. (For a sum-
mary of the action of colchicum, see a paper by Dr. Macdagan,
Edinburgh Monthly Journal, December 1851.)

A decoction of Hellebore (Bear's foot tea) is a popular remedy
for worms in some parts of the country. When thus adminis-
tered to children, it has in several instances caused convulsions
and death. It is in all cases a dangerous substance in the
hands of the ignorant.

Digitalis. (Foxglove.) Digitalia.

This plant, whether in the form of powder, extract, tincture,
or infusion, is a poison, acting both on the brain and alimentary
canal. The leaves appear to have the most powerful
effect. A case of poisoning by foxglove was the subject of a
criminal trial at the Old Bailey in Oct. 1826. A quack was
indicted for the manslaughter of a boy under the following cir-
cumstances:—He prescribed for a trivial complaint six ounces
of a strong decoction of the leaves. The boy was soon attacked
with vomiting, purging, and severe pain in the abdomen. After
some time, he became lethargic, and slept for several hours;
in the night he was seized with convulsions. The pupils were
dilated and insensible, the pulse slow, small, and irregular;
coma followed, and the boy died twenty-two hours after taking
the poison. On inspection, the membranes of the brain were
found much injected, and the mucous lining of the stomach was
partially inflamed. The prisoner was acquitted of the charge,
because he had only given his advice on the application of the
friends of the deceased! (Ed. Med. and Surg. Jour, xxvii. 223.)
For cases of recovery from a strong dose of the infusion, see
Med. Gaz. xxxiv. 659; and L’Union Médicale, 24 Août, 1848.
On the other hand, a case in which an infusion of the root proved
fatal is reported in the Lancet, July 14, 1849, p. 31. Acci-
dents sometimes occur from the medicinal use of the tincture.
In a late number of the Medical Gazette is the account of a case
where, from a dose of the tincture too frequently repeated, the
person was attacked with restlessness, thirst, inflamed eyes, and other serious symptoms. The medicinal dose of the infusion is from half an ounce to one ounce, — of the tincture, from ten minims to forty, — of the powder, from half a grain to one grain and a half.

**Conium Maculatum. (Common Hemlock.)**

The leaves and roots of common hemlock, with those of the **Cicuta Virosa** (Water Hemlock), **Aethusa Cynapium** (Fool's Parsley), **Genanthe Crocata** (Hemlock Water Dropwort), have frequently given rise to accidents. The symptoms which they produce are dizziness of sight, giddiness, delirium, swelling with pain in the abdomen, vomiting and purging. Convulsions are sometimes observed. Death commonly takes place rapidly, and the appearances are slight; sometimes amounting merely to congestion of the brain, with slight inflammatory redness of the stomach and bowels.

It is rare that the question of poisoning by hemlock comes before a judicial tribunal. One case of this kind was, however, submitted to me in 1848. (Reg. v. Bowyer, Ipswich Summer Ass. 1848.) In this instance a child died in an hour after swallowing part of a teaspoonful of a decoction of hemlock, alleged to have been administered by the mother. The woman was acquitted for want of proof. There were no morbid appearances in the stomach, nor any trace of hemlock leaves in the stomach or bowels. The absence of leaves in the contents of the stomach was accounted for by the fact that the prisoner had made a decoction and had allowed the leaves to subside to the bottom of the tea-cup, the child taking only the upper stratum of clear liquid.

A case of poisoning by hemlock is reported by Dr. Bennett in the Edin. Med. and Surg. Journal for July 1845, p. 169. (See also, On Poisons.) The reader will find some remarks on its active principle, **Conia or Conicine**, by Orfila, in the Annales d'Hygiène, 1831, ii. 224.

**Genanthe Crocata. (Hemlock Water Dropwort.)**

This appears to be the most fatal among the umbelliferous plants. In February 1834, four convicts at Woolwich lost their lives by eating the roots of this vegetable, which they had mistaken for parsnips. One died in less than an hour. (For an account of these cases, see Med. Gaz. May 1844.) On inspection their stomachs were found completely filled with slices of the root. Ten others who had also partaken of the root suffered severely, but recovered. This is one of the most virulent of English vegetable poisons. It is found growing abundantly in the south of Ireland. Dr. Pickells has collected thirty cases of death from the eating of the root, — the quantity taken in one
instance did not exceed the top of the finger in size. The symptoms were insensibility, tetanus, delirium, and insanity. Dr. Christison states that he has not found this plant, as it grows in Scotland, to be poisonous; but it is an active poison as it grows in England, Wales and Ireland.

In Sept. 1853, four children ate some of the roots of this plant, the quantity taken being equal in size to a man’s thumb. This was at 2 p.m. Four hours afterwards, according to the report of Dr. Nevins, one of them, a boy, was perfectly insensible, the face livid and turgid. He had previously vomited blood, and bloody mucus oozed from his mouth on admission. There were violent convulsions affecting the flexor muscles. The trunk was powerfully bent forward, the hands clenched even after death, and the jaws were rigidly closed. The respiration was spasmodic. The pupils were at first contracted, but afterwards dilated; they acted very feebly under the stimulus of light. The pulse was almost imperceptible. This state continued until death, which occurred twelve hours after the taking of the poison. There was no return of consciousness, and the spasmodic contraction continued with slight intermissions as long as he lived. The other children recovered. One was insensible and convulsed; a third had only abdominal pain and no cerebral symptoms. The quantity eaten in the latter cases was unknown. (Mr. Kesteven’s Quarterly Report on Toxicology, April 1854, p. 582, from Association Journal of December 2nd, 1853.) In April 1857, two fatal cases occurred at West Boldon in Durham. Two labourers ate some of the root of the Ænanthe. They were found soon afterwards lying insensible and speechless, their faces livid, tongues swollen and protruded, and there were convulsive movements of their teeth, frothy mucus with blood about their mouths, eyes full and projecting, pupils dilated, breathing sterterous and laboured, with occasional general convulsions. They both died in an hour and a half from the time at which they were first discovered. On inspection, it was found that there had been haemorrhage from the ears; the abdomen was livid and swollen. The stomach contained a greasy liquid with some of the partly digested roots; on removing this, the membrane was congested and softened. The lungs were engorged with dark liquid blood, and the blood contained in the heart was in a similar state. Mr. Boyle, to whom these cases occurred, forwarded to me a portion of the roots, and there is no doubt that they were the roots of the Ænanthe crocata.

No poisonous principle has yet been separated from this plant; but its effects are as formidable and somewhat similar to those produced by the poison of the rattle-snake.

Æthusa Cynapium.—The following case of poisoning by this plant, is reported in the Medicinisches Jahrbuch. A woman
gave to two of her children some soup in which she had boiled the root of this plant, mistaking it for parsley. They were both seized with severe pain in the abdomen, and the next morning one of them, a boy, aged eight years, was in a state of perfect unconsciousness, and his jaws were spasmodically fixed. The abdomen was swollen; there was vomiting of bloody mucus, with obstinate purging, — the arms and legs were cold, and the whole body was convulsed. He died in twenty-four hours. The only appearances met with were redness of the lining membrane of the gullet and trachea, with slight congestion of the stomach and duodenum.

**Datura Stramonium. (Thornapple.) Datura.**

The following case, which occurred to Mr. Mash of Northampton, may be taken as an example of the effects produced by this plant, all the parts of which, but especially the seeds and fruit, are poisonous. A woman, aged thirty-six, took two teacupsful of infusion of stramonium leaves, by mistake for senna tea. In about ten minutes she was seized with dimness of sight, giddiness, and fainting. In two hours she was quite insensible; the pupils were fixed and dilated, all the muscles of the body convulsed, the countenance flushed, and the pulse full and slow. The stomach pump was applied, and in the course of a few hours she recovered, suffering, however, from indistinctness of vision and giddiness. (Med. Gaz. viii. 603.) Stramonium leaves are frequently smoked with tobacco for the relief of asthma. In the return of the Registrar-General for April 1856, there is the record of one death from this cause. The seeds of this plant have been known to produce furious delirium; and a case is mentioned by Sauvages of an old man of sixty, who, after taking this poison, became intoxicated, maniacal, and lost the power of speech. He remained in a lethargic state for five hours. Several fatal cases are reported, one of which terminated in six hours. Dr. Thomson relates the case of a child, aged two years, who swallowed sixteen grains of the seeds. Maniacal delirium supervened; the symptoms resembled those of hydrophobia, and death took place in twenty-four hours. This plant has been used by robbers for the purpose of stupefying those whom they intend to attack. A case of poisoning by thornapple is reported in Henke's Zeit-schrift der S. A. 1837, i. H.; and another in the Lancet, April 1845, p. 47. Dr. Zechmeister has reported the case of a boy, aged five years, from which it would appear that the vapour of the full-blown flowers is capable of giving rise to well-marked symptoms of poisoning. (Oesterreich. Med. Wochenschr. 19 Juli, 1845.) Other cases of poisoning by stramonium will be found in the Prov. Journal, Dec. 24, 1851, p. 699; and Lancet, May 31, 1851, p. 599.
"Forty" had administered to her, by mistake, seventy minims of Fleming's tincture of the root mixed with one grain of acetate of morphia. This was about seven o'clock in the morning. In a few minutes she became very thirsty, complained of a burning sensation and pain in her stomach, to relieve which she swallowed a quantity of cold water. In fifteen minutes there was violent vomiting, which continued for two hours. She lost the power of standing, and was very restless. The pain in the stomach increased. After the first hour she was unable to do more than turn her head and vomit. There was violent straining as well as convulsive movements of the muscles. At nine o'clock she had a stuporized look, complained of giddiness, and was covered with a cold sweat. At ten o'clock she was quiet as if asleep. She was conscious until shortly before her death, which took place in about four hours after she had taken the poison. There were no general convulsions; the pain in the stomach was well marked throughout. On inspection, the face and lips were found swollen and dark-coloured, eyes bright, pupils dilated, and the muscular system rigid. The membranes of the brain were congested, but the brain itself was firm and healthy. The lungs were healthy; there was merely cadaveric congestion from gravitation. The heart was flaccid, uterus congested, bladder empty, and sphincter and relaxed. The stomach contained some mucus, and the membrane at the larger curvature was injected (reddened) in patches, but otherwise natural. The mucous membrane of the duodenum was in a high state of inflammation, abraded in patches, softened, and broken down. Some spots were of a very dark colour, passing to mortification. It is proper to observe that the deceased died on the 8th January, and the inspection was not made until the 14th. (Report by Dr. O'Bryen, Association Med. Jour. Jan. 28, 1833, p. 92. See also a case in the Lancet, 1833, vol. i. p. 467.)

In July 1833 a healthy young man lost his life at Glasgow, by reason of his having taken a mixture containing twenty-five minims of tincture of aconite, twenty minims of tincture of belladonna, and a drachm of the tincture of musk. The tincture in this case was prepared with sixteen ounces of the root of aconite to thirty fluid ounces of spirit. The mixture was swallowed at 6.30; the patient walked to a friend's house about three-quarters of a mile distant, which he reached at 7.20. He then complained of being sick, and of a tingling sensation in his hands and arms. In a short time his hands and arms were so numbed and powerless, that when he raised them he could not keep them up. Vomiting came on, with convulsive movements of the body, the pulse could not be felt, and the patient, retaining his consciousness to the last, died within three hours from the time of taking the poison. The body was inspected two days after death by Dr. Euston. The veins of the brain were unusually congested,
POISONING BY TINCTURE OF ACONITE.

It is stated that one drachm of the root has been known to prove fatal; but it is probable that less than this would cause death. In November 1856, Mr. Hatfield forwarded to me four small slices of the root, taken from the stomach of a man who died in three hours. The quantity which he had taken was unknown; but none was thrown off by vomiting so far as could be ascertained. The symptoms within half an hour of death were burning pain in the stomach, parched mouth,—intense thirst,—retching and vomiting of a tenacious mucus,—cold perspiring skin,—imperceptible pulse and a feeling of deadly sickness. On inspection, there was congestion of the brain as well as of its membranes; and the heart was flaccid with blood on the right side. The stomach contained much half-digested food, with four slices of aconite root apparently unaltered. The mucous membrane presented a slight reddish-brown patch at the greater end of the size of half-a-crown. It was otherwise healthy as well as the other organs. (For an account of poisoning by this plant I must refer the reader to a paper by Dr. Geoghegan, Dub. Journ. Med. Sci. Vol. xix. p. 403.)

Tincture.—There are numerous instances recorded of poisoning by aconite under the form of tincture. In a case which occurred to M. Devay (Cormack's Edinburgh Journal, April 1844), a man is stated to have recovered in three days after having taken upwards of ten drachms of the tincture (only infused for a day); but this could have contained no aconitine. The late Dr. Male of Birmingham died from the effects of not more than eighty drops taken in ten doses, over a period of four days,—the largest quantity taken at once being ten drops. (Prov. Med. and Surg. Journ. August 20, 1845, p. 535; also Med. Gaz. xxxvi. p. 861.) The late Dr. Pereira informed me that he had known tingling and general numbness of the limbs produced in hysterical females by a dose of only five minims of a carefully prepared tincture. Dr. Topham has published an account of the symptoms produced by fifteen minims of the tincture of the root of aconite. Immediately after taking the poison in a mixture into which it was put by mistake, the patient (a woman aged twenty-seven) felt a sensation of numbness in the tongue, with difficulty of swallowing. There were convulsive twitchings of the muscles of the face, and she lost the power of walking. There was complete unconsciousness, which continued for two hours, when she began to recover. The pupils were observed to be slightly contracted. The intensity of the symptoms varied at intervals, and came on in paroxysms. They indicated great disorder of the nervous system. The next day she had numbness in both arms, but she rapidly and perfectly recovered. (Lancet, July 19, 1851, p. 56.)

In January 1853, a case of poisoning by tincture of aconite occurred at a convent near Bristol. One of the inmates named
"Forty" had administered to her, by mistake, seventy minims of Fleming's tincture of the root mixed with one grain of acetate of morphia. This was about seven o'clock in the morning. In a few minutes she became very thirsty, complained of a burning sensation and pain in her stomach, to relieve which she swallowed a quantity of cold water. In fifteen minutes there was violent vomiting, which continued for two hours. She lost the power of standing, and was very restless. The pain in the stomach increased. After the first hour she was unable to do more than turn her head and vomit. There was violent straining as well as convulsive movements of the muscles. At nine o'clock she had a stupified look, complained of giddiness, and was covered with a cold sweat. At ten o'clock she was quiet as if asleep. She was conscious until shortly before her death, which took place in about four hours after she had taken the poison. There were no general convulsions: the pain in the stomach was well marked throughout. On inspection, the face and lips were found swollen and dark-coloured, eyes bright, pupils dilated, and the muscular system rigid. The membranes of the brain were congested, but the brain itself was firm and healthy. The lungs were healthy: there was merely cadaveric congestion from gravitation. The heart was flaccid, uterus congested, bladder empty, and sphincter ani relaxed. The stomach contained some mucus, and the membrane at the larger curvature was injected (reddened) in patches, but otherwise natural. The mucous membrane of the duodenum was in a high state of inflammation, abraded in patches, softened, and broken down. Some spots were of a very dark colour, passing to mortification. It is proper to observe that the deceased died on the 5th January, and the inspection was not made until the 14th. (Report by Dr. O'Brien, Association Med. Jour. Jan. 28, 1853, p. 92. See also a case in the Lancet, 1855, vol. i. p. 467.)

In July 1853, a healthy young man lost his life at Glasgow, by reason of his having taken a mixture containing twenty-five minims of tincture ofaconite, twenty minims of tincture of belladonna, and a drachm of the tincture of musk. The tincture in this case was prepared with sixteen ounces of the root ofaconite to thirty fluid ounces of spirit. The mixture was swallowed at 6:30; the patient walked to a friend's house about three-quarters of a mile distant, which he reached at 7:20. He then complained of being sick, and of a tingling sensation in his hands and arms. In a short time his hands and arms were so benumbed and powerless, that when he raised them he could not keep them up. Vomiting came on, with convulsive movements of the body, the pulse could not be felt, and the patient, retaining his consciousness to the last, died within three hours from the time of taking the poison. The body was inspected two days after death by Dr. Easton. The veins of the brain were unusually congested,
and there was a great quantity of serum effused in the arachnoid (membranes). The lungs and the right cavities of the heart were gorged with dark blood. The lining membrane of the stomach was of a dark red colour. Death was very properly referred by Dr. Easton to the action of aconite. (Assoc. Med. Jour. Sept. 16, 1833, p. 817.) A Revenue officer at the London Custom House lost his life by merely tasting Fleming’s tincture of aconite, under the supposition that it was flavoured spirit. He was able to walk from the Custom House over London Bridge, but he died in about four hours after taking the poison.

The tincture of aconite according to the London and Dublin pharmacopoeias is made by infusing the root in rectified spirit. Fleming’s tincture is also made with the root, but with half the quantity of spirit. The medicinal dose is variously stated, owing to the great difference in the strength of this preparation. It should not exceed five minims. The late Dr. Pereira states that a dose of six minims administered twice produced the most alarming symptoms in a healthy young man. (Mat. Med. Vol. ii. pt. ii. p. 693.) Fleming’s tincture is a powerful preparation, and might, from its appearance, be mistaken for sherry wine. Since this tincture is as deadly in its operation as prussic acid, and so many accidents have occurred from the use of it, it seems advisable that its strength should be reduced.

Aconitina. — The alkaloidal base of this plant, Aconitina, is a most formidable poison, exceeding all others in its effects. According to the late Dr. Pereira, it is strongly retained in the vegetable tissues even after their compression. Hence the uncertainty of the strength of the preparations of aconite. Although there are few poisons so deadly as aconitina, — for even experiments on it require to be made with the greatest caution, — a singular instance is recorded by Dr. G. Bird in which a gentleman recovered after having taken two grains and a half. (Med. Gaz. Vol. xli. p. 30.) In this case, however, there appears to have been early and copious vomiting, so that the greater part of the poison had probably been discharged. Enough had been absorbed, however, to produce most serious symptoms. There was collapse, coldness of surface, cold perspiration, heart’s action scarcely perceptible, and constant spasmodic vomiting of a violent kind.

Atropa Belladonna. (Deadly Nightshade.) Atropia.

This plant is poisonous in its root, leaves, and berries. Children have frequently suffered severely from eating the shining black berries of the belladonna. The symptoms observed have been heat and dryness of the mouth, throat, and fauces, — giddiness, double vision, with delirium, convulsions, stupor, and lethargy;
sometimes nausea and vomiting. The pupils are much dilated, and the eyes are insensible to light. In two cases reported by Mr. Tufnell, the pupils were found contracted during sleep, although dilated in the waking state. (Dub. Med. Press, Jan. 5, 1853, p. 2; Journal de Chimie Méd. 1853, p. 695.) In fatal cases, on inspection, the vessels of the brain have been found full of dark-coloured blood. Several deaths from the effects of the berries occurred in this metropolis in the autumn of 1846. Dr. Scharf has published a case of poisoning by the root of belladonna infused in four ounces of water and injected as a clyster. In a very short time the patient fell into a state of complete narcotism, and died in five hours. (Casper's Wochenchrift, February 1845.) Mr. Iliff, Jun. has given an account of the effects produced on himself by a dose of nine grains of the extract of belladonna, for which I must refer the reader to the Lancet (Dec. 1, 1849, p. 756. See also Med. Times, Aug. 30, p. 234. and Ann. d'Hygiène, 1853, i. 417). In the latter case the members of a family were poisoned by the extract, but they all recovered. In the Medical Gazette (Vol. xliii. p. 589), will be found the report of an inquest in a case of alleged poisoning by belladonna, involving many points regarding this poison. The extract of belladonna is no doubt subject to great variation in strength, and this may explain certain exceptional cases in which persons have recovered after having taken large doses of this compound. Mr. Edwards has reported a case in which a female, aged 34, recovered after having swallowed a draught of the extract by mistake. (Lancet, May 24, 1851, p. 568.) It has happened that the extract of belladonna has been accidentally substituted for extract of dandelion. (Pharm. Jour., Feb. 1853, 404.) In a case which occurred to Mr. Solly, a man took a scruple by mistake. No symptoms occurred for two hours. He then suffered from dryness of the throat, difficulty of swallowing, fanciful delusions, rambling incoherent conversation: pupils dilated and insensible to light, eyes prominent with a vacant stare, drowsiness, feeble and irregular pulse, and loss of muscular power. He recovered the next day, under the use of emetics. (Lancet, Feb. 3, 1855, p. 121.)

Atropia.—The alkaloidal principle of this plant, Atropia, is a powerful poison. In November, 1850, Mr. Sells, of Guildford, forwarded to me for examination the stomach of a young man who had poisoned himself by taking two grains of atropia. He took the dose on going to bed. He was heard to snore heavily during the night, and was found dead about seven o'clock in the morning, lying on his right side, the surface livid, the limbs rigid and contracted, and with a little brown matter issuing from the mouth. The pupils were much dilated. The mucous membrane of the stomach presented a diffused redness, which might have arisen from some brandy which he had swallowed. No
trace of the poison could be detected in the stomach or its contents. In the Association Medical Journal (Sept. 16, 1853, p. 818) will be found the report of a case in which all the symptoms of poisoning by belladonna arose from the application of a weak solution of atropia and water to the conjunctiva.

**Nicotiana Tabacum. (Tobacco.)**

This well-known plant contains a poisonous volatile alkaloidal principle, nicotina, which forms from two to seven per cent. of ordinary tobacco leaves. It is a colourless oleaginous liquid of a powerful tobacco odour, hot acrid taste, and soluble in alcohol, water, and ether. It has a strong alkaline reaction. A remarkable case of poisoning by nicotina will be found in the Annales d’Hygiène, 1851, ii. p. 167: I refer to that of the Count Bocarme, who was tried and executed in Belgium for the murder of his brother-in-law. The properties of the poisonous principle have been fully investigated by Orfila. (Ann. d’Hygiène, 1851, ii. 147.) Tobacco has proved fatal, when used improperly or by mistake, in the form of an injection; but very little is known concerning the few cases in which it has destroyed life. The symptoms have been nausea, vomiting, giddiness, convulsions, and coma, followed by death in a few hours. In one case it destroyed life in three-quarters of an hour. In another, reported by Mr. Eade, a girl, aged 18, injected into a clyster a decoction made by boiling three drachms of common shag tobacco in a pint of water. In half an hour she complained of faintness and feeling sick, and in another half hour she became quite collapsed, with cold sweats, vomited, was slightly convulsed, and died in an hour and a half from the time at which she injected the clyster. On inspection, the heart was found very flaccid; there were three drachms of black fluid blood in the ventricles. The stomach contained food, but had no unusual appearance. The intestines presented no trace of inflammation or redness in any part, and there was no smell of tobacco (thirty-six hours after death) either in the intestines or in any part of the body. The head was not examined. (Med. Gaz. xlv. p. 823.) These facts tend to show that tobacco is rather a narcotic or cerebral than a cerebro-spinal poison.

**Lobelia Inflata. (Indian Tobacco.)**

The powdered leaves of Indian tobacco (Lobelia Inflata) contain an acrid principle which is capable of producing poisonous effects on the brain and spinal marrow, attended with irritation of the stomach and bowels. As a poison it has only recently become known in this country. Witherer relates that in one instance it produced at first violent vomiting in the person for whom it was prescribed; but the medicine was repeated until it was no longer ejected from the stomach. The patient suffered severe pain, and
speedily died: stupor and convulsions having preceded death. The powdered leaves and seeds are employed by a certain class of quacks, (calling themselves "Medical Botanists,"") in England and in the United States, as "vegetable medicine;" and fatal accidents have arisen from the substances having been prescribed in excessive doses. When administered in doses of from ten to twenty grains, lobelia acts as an emetic; but in larger quantity it acts as a poison. It also appears that even ordinary medicinal doses affect some individuals with great severity; owing, probably, to idiosyncrasy. There is an erroneous idea, that this is a useful medicine, and not a poison, although it may be either, according to the mode in which it is employed.

A case occurred in which a man lost his life by swallowing one drachm of the powdered leaves, prescribed by a quack. This person was seen by a medical practitioner soon after he had taken the poison; he was evidently suffering great pain, but he was quite unconscious, — the pulse small, the pupils strongly contracted, and insensible to light. He had vomited the greater part of the poison. He suffered from spasmodic twitchings of the face, sank into a state of complete insensitivity, and died in about thirty-six hours. On inspection, some fluid was found in the stomach, but none of the powder. The mucous membrane was intensely inflamed, and the vessels of the brain were strongly congested. (Pharm. Times, May 1, 1847, p. 182.)

Within the last few years, there have been several inquests and trials for manslaughter in this country as the result of the administration of the leaves of the Lobelia Inflata by ignorant quacks. The medical evidence given on these trials shows that in large doses it is a most noxious drug. (See Medical Gazette, Vol. xlv., pp. 383 and 433, also Vol. xlvii. p. 384; also Lancet, March 5, 1853, p. 237; Pharm. Jour. Aug. 1851, p. 87; and for some remarks on the action of this poison see a paper by Mr. Curtis and Dr. Pearson, Med. Gaz. 1850, Vol. xlvii. p. 285; also Pereira, Mat. Med. Vol. ii. pt. ii. p. 12.) Those impostors who profit by the prescription and sale of the drug among the ignorant poor, maintain the doctrine that it cannot kill, and never has been known to destroy life! From inquiries recently made, I have reason to believe that deaths from lobelia still frequently occur in the northern counties. The noxious medicine is taken in secrecy, under the direction of quacks, and any death arising from it is always referred to other causes. The late Sergeant Wilkins was a great and successful defender of this class of poisoners: out of several trials for manslaughter, in which the cause of death, medically speaking, was clear, he succeeded in winning a favourable verdict from the juries. In July, 1856, one of these quacks was, however, convicted on a charge of manslaughter, for killing a woman with overdoses of lobelia. Severe pain, followed by loss
of consciousness, and congestion of the brain, were the chief symptoms preceding death in this case. The admission that, in proper doses, it was a useful remedy in spasmodic asthma was of no avail on this occasion. The man was sentenced to three months' imprisonment. (Reg. v. Boyden or Jackson, Lincoln Summer Assizes, 1856.)

**COCCULUS INDICUS.**

This is the fruit or berry of the Menispernum Cocculus, imported from the East Indies. It contains from one to two per cent. of a poisonous alkaloid (*Picrotoxius*), which resides in the substance of the berry or kernel, and not in the husk. The seeds give rise to vomiting and griping pains, and a decoction of them produces stupor and intoxication. There is, so far as I am aware, only one well-authenticated instance of this substance having proved fatal to man. (See Traill's Outlines, 146.) London porter and ale are considered, and in some instances, I believe, with propriety, to owe their intoxicating properties to a decoction or extract of these berries—a fraud not easily susceptible of detection. This fraud is perpetrated by a low class of publicans. They lower the beer by water and salt, and then give it an intoxicating property by a poisonous extract. Cocculus Indicus is also used by robbers to intoxicate their victims; and to this form of intoxication the term "hocussing" is applied. This substance is applied to no useful purpose whatever, either in medicine or the arts; and, under a proper system of medical police, its importation would be strictly prohibited. For some account of the properties of picrotoxius, see a paper by Dr. Glover, Lancet, Jan. 11, 1851, p. 47; also Edinburgh Monthly Jour., April 1851, p. 306.

**CYTISUS LABURNUM. THE BARK.**

The bark and seeds of the common laburnum contain an active poison called *Cytisine*. A case of poisoning by laburnum bark, which was the subject of a criminal trial at Inverness, has been reported by Dr. Chrisison (Ed. Med. and S. J. Oct. 1843). A youth, with the intention of merely producing vomiting in one of his fellow-servants, a female, put some dry laburnum bark into the broth which was being prepared for their dinner. The cook, who remarked "a strong peculiar taste" in the broth, soon became very ill, and in five minutes was attacked with violent vomiting. The account of the symptoms is imperfect; for the cause of them was not even suspected until six months afterwards. The vomiting continued thirty-six hours; was accompanied by shivering—pain in the abdomen, especially in the stomach,—and great feebleness, with severe purging. These symptoms continued, more or less, for a period of eight months; and
she fell off in flesh and strength. At this period she was seen by a physician, who had been called on by the law-authorities to investigate the case. She was then suffering from gastro-intestinal irritation, vomiting after food, pain in the abdomen increased by pressure, purging, violent straining, and bloody stools, with other serious symptoms. The medical opinion was that she was then in a highly dangerous state. The woman did not recover until the following April. There was no doubt, from the investigation made by Dr. Ross and Dr. Christieon, that her protracted illness was really due to the effects of the laburnum bark.

Seeds.—Dr. Traill met with two cases of poisoning by the seeds. I am indebted to Mr. Hake, a former pupil, for the subjoined cases of poisoning by laburnum pods and seeds, which occurred in September 1851. Two children, the one aged two, and the other three years, had been seen playing together, and on returning home they appeared unwell, and soon afterwards vomited. They had been seen with laburnum pods in their hands, and some seeds with portions of the pods were mixed with the vomited matter. Both children were pallid and exhausted, with a slow and somewhat feeble pulse. The pupils were natural. An emetic was given, but no more seeds were ejected: the pulse increased in volume and frequency, and the next day the children had recovered their usual health. In October 1856, twelve children, at Otley in Yorkshire, were attacked with symptoms of poisoning in consequence of having swallowed these seeds. They recovered under the use of emetics. (Lancet, Nov. 1, 1856, p. 497.)

Flowers.—Mr. Barber, of Stamford, communicated to me, in June 1848, the particulars of a case which show that even the flowers of this plant are highly noxious. A child between three and four years of age ate twelve laburnum flowers, and in about fifteen minutes it complained of sickness and severe pain in the stomach. The child vomited a quantity of mucus mixed with the yellow petals of the laburnum. An emetic was given: this cleared the stomach, and the child recovered. There was no purging. (Guy's Hosp. Reports, Oct. 1850, p. 219.) A case in which a child suffered from symptoms of a nervous kind by reason of its having eaten laburnum flowers, is described by Mr. North in the Medical and Physical Journal, Vol. lxii. page 86.

Fungi. Mushrooms.

Poisoning by mushrooms is by no means unusual as the result of accident; and numerous fatal cases of this description are recorded. There do not appear to be any satisfactory rules for distinguishing mushrooms which are wholesome from those which are poisonous. The best test is that assigned by Dr.
POISONING BY MUSHROOMS.

Christison—namely, that the poisonous vegetable has an astringent styptic taste; and perhaps also a disagreeable but certainly a pungent odour. A correspondent informs me that one popular test for detecting a poisonous mushroom is to boil it with a silver spoon in the water. The silver is tarnished if it be poisonous. It need hardly be observed that the tarnish depends on the presence of sulphur, which may be a constituent of the innocuous as well as of the noxious kind. The poisonous principle is called Fungin, but its nature and properties are but imperfectly known. These fungi act sometimes as narcotics, at others as irritants. It is difficult to generalise where observations are so limited; but it would appear from the reports of several cases which I have collected, that when the cerebral symptoms are excited, they come on soon after the meal at which the mushrooms have been eaten, and they are manifested by giddiness, dimness of sight, and debility. Dr. Peddie has related three cases of poisoning by mushrooms, in which they acted as a pure narcotic, or cerebral poison; there was no pain in the abdomen, nor irritation in the alimentary canal (Ed. M. and S. J. xliv. 200). The cerebral symptoms began in half an hour with giddiness and stupor. The first effect with one patient was, that every object appeared to him to be of a blue colour. The three patients recovered—two of them rapidly. When the drowsiness passes off there is generally nausea with vomiting. If the symptoms do not occur until many hours after the meal, they partake more of the characters of irritation;—indicated by pain and swelling of the abdomen, vomiting and purging. Several cases, in which the symptoms did not appear until after the lapse of fourteen hours, are reported in the Medical Gazette (Vol. xxv. p. 118). In some instances the symptoms of poisoning have not commenced until after the lapse of thirty hours; and in these, narcotism followed the symptoms of irritation. It might be supposed that these different effects were due to different properties in the mushrooms; but the same fungi have acted on members of the same family, in one case like irritants, and in another like narcotics. In some persons, even the edible mushrooms will produce disorder of the stomach and bowels by the effect of idiosyncrasy. In most of these cases recovery takes place, especially if vomiting be early induced: in few instances which have proved fatal, there has been more or less inflammation in the stomach and bowels, with congestion of the vessels of the brain. [Reports of cases of death from mushrooms will be found in the Medical Gazette, xlvi. p. 307, and xlvi. p. 673; Journ. de Chim. Méd. 1853, 694.] Even Cutsup, or Ketchup, a liquor made from mushrooms, has been known to produce serious effects. (Dub. Med. Press, Sept. 24, 1845, p. 195.)
POISONING BY YEW.

**Taxus Baccata.** (Yew.)

It has been long known, that the berries and leaves of the yew-tree are poisonous to cattle; — they act very energetically, and produce death in a few hours, sometimes without vomiting or purging. It is stated by Dr. Percival, that a tablespoonful of the fresh leaves was administered to three children of five, four, and three years of age, as a vermifuge. Yawning and listlessness soon succeeded; the eldest vomited a little, and complained of pain in the abdomen, but the other two suffered no pain. They all died within a few hours of each other. A case of poisoning by the berries of this tree was published a few years since by Mr. Hurt of Mansfield. A child, aged three years and a half, ate a quantity of yew-berries about eleven o'clock. In an hour afterwards the child appeared ill, but did not complain of any pain. It vomited part of its dinner, mixed with some of the berries. A medical man was sent for, but the child died in convulsions before he arrived. On inspection, the stomach was found filled with mucus and the half-digested pulp of the berries and seeds. There were patches of redness in the mucous membrane, and this was so much softened that it could be detached with the slightest friction. The small intestines were also inflamed.

The symptoms produced by yew-leaves and berries are pretty uniform in character: convulsions, insensibility, coma, dilated pupils, pale countenance, small pulse, and cold extremities, are the most prominent. Vomiting and purging are also observed among the symptoms. In two cases of recent occurrence, the subject of one, a girl, about five years of age, died in a comatose state in four hours after she had eaten the berries, and the other, a boy, aged four years, died nineteen days after taking the berries, obviously from severe inflammation of the bowels. (See Prov. Journal, Nov. 29, 1848, 662, and Dec. 27, p. 708.)

There is a vulgar but erroneous notion that the yew-leaves are not poisonous when fresh, and that in any case they act only mechanically. A case related above shows the fallacy of the opinion, and the other cases prove that there is a specific poison in the yew, since it exists in the berries as well as in the leaves. If cattle recover from the primary effects on the nervous system they are liable to die, after several days, from inflammation of the bowels. On one occasion I examined the viscera of an ox which had obviously died from the effects of yew-leaves. In some parts of the intestines gangrene had taken place.

**Ligustrum Vulgare.** (Privet.)

The Privet is not commonly enumerated among vegetable poisons. No reference is made to this plant in the works of Wib-
mer, Orfila, Christison, and other writers on toxicology, and yet it would appear, from the subjoined cases, for the brief particulars of which I am indebted to Mr. Ward of Ollerton, that the berries may exert a poisonous action. In December 1853, three children ate the berries of the privet; two of them, a boy of three years of age and a girl of six, eating them rather freely. They suffered from violent purging, and when seen by a medical man the little boy was found pulseless, cold, and before death was frequently and violently convulsed. The girl was in a state of collapse, but rallied a little under treatment: she soon afterwards died convulsed. The surviving child, who had only tasted the berries, did not suffer, and she was enabled to point out the shrub, the berries of which they had gathered. So far as I know, these are the only cases on record in which the berries of the privet have proved fatal. According to London, they are eaten by birds when other sources of food fail.
WOUNDS.

CHAPTER XX.

VARIOUS SURGICAL DEFINITIONS OF A WOUND—INJURY TO THE SKIN—LEGAL DEFINITION—AN ABRASION OF THE CUTICLE NOT A WOUND—INJURIES OF THE MUCOUS MEMBRANE AND DISLOCATIONS WOUNDS?—WOUNDS DANGEROUS TO LIFE—THE DANGER IMMINENT—RULES REGARDING DYING DECLARATIONS—WOUNDS PRODUCING GRIEVOUS BODILY HARM. INTENT OF THE ACCUSED, A QUESTION FOR THE JURY.

When a person is the subject of a wound or external injury, from the effects of which he ultimately recovers, a medical witness is often rigorously examined with respect to the precise nature of the injury, and how far it involved a risk of life. The answers to these questions may have an important influence on the defence of a prisoner, when the crime is charged under particular forms of indictment.

Definition of a wound.—It may, I think, be safely asserted, that we shall look in vain for any consistent definition of a wound, in works on medicine and surgery. A wound is, perhaps, most commonly defined to be, a “recent solution of continuity in the soft parts, suddenly occasioned by external causes.” Yet they who adopt this view, do not regard as wounds, ruptures of the liver or spleen, burns by heated bodies, or simple dislocations and fractures; although these injuries are comprehended in such a definition. The following definitions of a wound were furnished to me by three eminent surgeons:

“A solution of continuity from violence of any naturally continuous parts.”

“An external breach of continuity directly occasioned by violence.”

“An injury to an organic texture by mechanical or other violence.”

Owing to the unsettled meaning of the word wound, it has happened on more than one occasion that medical witnesses
WOUNDS. LEGAL DEFINITION.

have differed in their evidence; and some difficulty has arisen in the prosecution of criminal charges. It has been asserted, that, in order to constitute a wound, the skin should always be broken or injured; and this, as we shall see presently, is the interpretation commonly put upon the term by our judges. But those who have adopted this view, do not regard burns produced either by heated metals, or corrosive liquids, as wounds; although there seems to be no good reason why, under the above definitions, they should be excluded. Technical difficulties of this kind, which only lead to the embarrassment of witnesses and to the acquittal of prisoners charged with serious offences, might be avoided if the medical witnesses of England were allowed to adopt the comprehensive definition sanctioned by the legal tribunals of certain States on the Continent, namely, that "a wound includes every description of personal injury, arising from whatever cause, applied externally." It may appear contrary to propriety to designate a contusion or fracture as a wound; but the common definitions will be found, on examination, to be equally inconsistent, and to be attended, in legal medicine, by evil results, inasmuch as they lead to acquittals, not upon the merits of the case, but upon the most trivial pretences. This could not happen if the above comprehensive definition was generally adopted. It appears to me, that in a case of this kind we should rather regard the wants of justice than the rules of surgery. If medico-legal cases fail from differences respecting the meaning of scientific terms among surgical writers, it is time that some fixed rule should be adopted. While the science of surgery cannot possibly suffer by such an innovation, the administration of the law will be rendered much more efficient. The Statute, 14 and 15 Vict. c.100, has, however, supplied a remedy for some of the evils which have hitherto arisen from a misdescription of personal injuries in indictments.

Legal definition.—It cannot be denied that an alteration in the use of medical terms must, in order to be attended with any good effects, receive the support of our legal authorities. This, probably, would not be long withheld, if good reasons for the change were afforded by medical witnesses. The present rule appears to be, that no injury constitutes a wound in law, unless the continuity of the skin be broken; so that in a case in which blows were inflicted with a hammer or iron-instrument sufficient to break the collar-bone, and violently bruise but not break the skin, it was held not to be a wounding within the statute. (R. v Wood, Matthew's Digest, 415.) The Act 1 Vict. c. 85, has in some measure provided for the punishment of persons guilty of inflicting such severe injuries, but still it has left the legal signification of the word wound, unsettled. The 14 and 15 Vict. c. 100, is still more precise, but this also avoids the definition of a wound.
In order to remove any difficulty in future cases, and to put an end to conflicting decisions, the Commissioners for codifying the Criminal law have recently suggested that *internal* breaches of continuity should be included under the term wound. They have defined a wound to be "that whereby the skin is divided either externally or internally." The late Mr. Justice Talford objected to this definition, because, in his opinion, the division of the skin internally without a division externally was impossible. The use of the word "skin" leads to ambiguity; and, in this instance, it shows that those who frame laws are not sufficiently careful in the selection of professional terms. The skin consists of the cuticle and cutis. It has been held on more than one occasion that an abrasion of the cuticle, or outer skin only, is not a wound. A man was tried at the Central Criminal Court in August, 1838, on a charge of cutting and wounding the prosecutor. The prisoner struck the prosecutor a severe blow on the temple with a heavy stone bottle, which was thereby broken in pieces. The prosecutor fell senseless, and it was a long time before he recovered from the effects of the violence. The medical witnesses in this case underwent a rigorous cross-examination by the prisoner's counsel, respecting the meaning of the word "wound." They said that there had been a separation of the cuticle or outer skin of the temple, although there was no absolute wound in the usual acceptation of the word. They further deposed that the prosecutor had lost the sight of his left eye, and the hearing of his left ear; and he was for a considerable time in a state of great danger, from which he had scarcely recovered. The prisoner's counsel contended that the injuries were not such as to constitute cutting and wounding in law. The judges said, in order that a wound, in contemplation of law, should have been inflicted, it was necessary that the whole skin, and not the mere cuticle, should have been separated and divided; and as the evidence did not show distinctly that there was such a wound, those counts of the indictment could not be sustained. The prisoner was found guilty of an assault. A division of the cutis or true skin has always been regarded as a wound, whether blood be effused or not. The boundary of the cutis towards the inside of the body is not easily determined; since there is a gradual transition of the cutis into the subjacent fibrous tissue, in which the fat and sudatory glands are contained. According to Quain and Sharpey (Elements of Anatomy, i. 285), the cutis measures in thickness from a quarter of a line to a line and a half (a line being about one-twelfth of an inch). It is thicker in some parts than in others. Taking the true skin, or cutis, at the thickness usually assigned, it is impossible to conceive that such a very thin layer of membrane as this can be divided internally without an external division being produced. **Allowing the maximum thickness of the eighth of an inch, it**
would be difficult for any medical man to affirm that a fractional part of this membrane had been divided internally, when there was no evidence of external separation; and it would be certainly impossible for him to prove it. What the Commissioners probably mean, are the structures beneath the skin. Further, their definition is vague and unsatisfactory, because it does not reach an important class of cases in which wounds are inflicted not in the skin, but in the mucous membrane lining the outlets of the body. Thus cuts, punctures, or lacerations of the lining membrane of the nostrils, mouth and throat, rectum and vagina, are undoubtedly wounds, although the skin may not be directly touched by the weapon. Injuries of a serious description have thus been frequently inflicted on females by cutting and pointed instruments; they have been hitherto properly treated as wounds, but they would not be comprised under this term by a strict adherence to the proposed definition. The subjoined case shows that an injury to the mucous membrane is regarded as a wound in law. The prisoner was charged with maliciously wounding a mare. He had thrust forcibly down the throat of the animal a stone, which had torn the fauces and oesophagus. It was objected that the injury was not a wounding within the statute, the parts injured being internal, and there being no proof of an external blow or violence. The judge who tried the case was of opinion that it fell within the statute. Blood had flowed from the broken skin, or membrane lining the throat, and the stone was forced into the flesh; and it had been held that the injury need not be "external" to bring the case within the statute. The prisoner was convicted. (Reg. v. Bolton, Norwich Summer Assizes, 1849.) Other cases, in which the vagina in females has been thus wounded are given under the section of Wounds of the Genital Organs.

Do all breaches of continuity involving the skin or mucous membrane fall under the head of wounds? Burns appear to constitute an exception; but there is no reason why a burn producing a destruction of the skin, as by a red-hot poker, should not be regarded and treated in law as a wound. No definition of a wound, medically or legally, can be contrived so as to exclude such an injury. The question, however, mainly to be considered is this — May not a breach of continuity be regarded as a wound, although neither the skin nor the mucous membrane is directly implicated in the injury? Is a simple dislocation or fracture a wound? Is a rupture of the bladder, liver, or other organ, suddenly caused by external violence without implicating the skin, to be regarded as a wound? In a case brought before the Queen's Bench in November, 1847, it was held that a dislocation was a wound. An action was brought against a medical practitioner for negligence in the treatment of a dislocation of the arm, and a verdict was returned for the plaintiff. An application was
made to the Court of Queen's Bench for a rule to show cause why there should not be a new trial, on the ground of a mis-
direction of the learned Chief Baron, who tried the case. The
declaration alleged that the plaintiff had employed the defendant,
who was a surgeon, for the treatment and cure of certain wounds,
fractures, bruises, complaints, and disorders; but the evidence
showed that the defendant had been employed to cure the plaint-
tiff of a dislocated arm. At the close of the plaintiff’s case, it
was submitted to the learned Chief Baron that there was no
word in the declaration which was applicable to the case: but
this objection was overruled. A dislocation, it was argued, was
neither a wound, bruise, nor fracture; and the words “com-
plaint and disorder” were not at all applicable to a surgical case,
but to internal complaints which required to be treated medically.
Lord Denman, in delivering the judgment of the Court, said,
“It is rather strange that the pleader should have omitted the
most appropriate word;” but we think the Chief Baron was
quite right.—Rule refused. With respect to fractures, it has
been stated (supra) in the case of Rex v. Wood (4 C. and P., p.
381), that a fracture of the collar-bone was not held to be a
wounding within the statute, because the skin was not broken.
There are, however, at least two recent cases in which contrary
decisions have been given. The first of these is Reg. v. Smith
(8 C. and P., 173). In this case prisoner struck prosecutor with
an iron hammer on the side of the face. A surgeon from the
London Hospital deposed that the lower jaw was broken in two
places; that the skin was broken internally but not externally.
There was not a great deal of blood effused. On the objection
being taken that this was not a wound within the statute, Den-
man, C. J., observed, “If it is the immediate effect of the injury,
we think we cannot distinguish this from the cases already
decided;” and Parke, J. (in summing up), said, “We were of
opinion that there was a wound, and, upon consideration, I am
more strongly of that opinion than I was at the outset. There
must be a wounding; but if there be a wound (whether there be
an effusion of blood or not), it is within the statute whether the
wound is internal or external.” The same point arose in another
case. (Reg. v. Worman, 1 Denison, C. C. 183.) This was an
indictment for inflicting a mortal wound; and a question arose
whether it was supported by proof of a blow which caused an
internal breach of the skin (although externally there were only
the appearances of a bruise). The death of the deceased had
been effected by a single blow on the head given by a piece of
wood; and the medical witness described the injury as follows:
“I found on examining the head no external breach of the skin.
I found a collection of blood in the back part of the head: the
deceased died from extravasation of blood, which pressed on the
brain. On examining the scalp, I found a collection of blood
WOUNDS DANGEROUS TO LIFE. 229

between the scalp and cranium, just above the spot where, within the cranium, I had found the pressure on the brain. I call that a contused wound with effusion of blood; that is the same thing as a bruise. The internal part of the skin was broken. Medically, we call the breaking of the skin, whether broken externally or internally, a wound. This case was reserved for the judges, and considered by Denman, Tindal, Pollock, Alderson, Williams, Cresswell, Parke, Cohman, Wightman, Paterson, Erle, and Platt. All thought that this internal wound was a sufficient wound to support the allegation in the indictment.

In each of these cases the Court appears to have been misled by the medical witnesses affirming that the skin (cutis) was broken internally but not externally. There is no doubt that they intended by this, not the cutis merely, but the areolar fatty tissue and soft parts beneath. Their evidence has, however, served to mislead the Commissioners, and to induce them to propose a faulty and erroneous definition. I know no instance in which a rupture of the bladder or liver, without any external injury, has been called a wound, although this term might be applied with as much propriety to this kind of injury as to a simple fracture or dislocation. The brain is sometimes lacerated by a blow on the skull which does not break the skin. This must be regarded as a wound of the brain; it admits of no other description. Two of the definitions given ante, p. 223, include all injuries of this kind; but it appears to me that the best definition which we can at present give to the word "wound," is that it should include "a breach of continuity in any of the structures of the body suddenly occasioned by violence." I have good authority for stating that these refinements and technicalities are not met with in the law of Scotland. The amount of injury inflicted, and the intention of the assailant, are alone regarded.

Wounds dangerous to life.—A medical witness is often asked whether a wound was or was not dangerous to life. In reference to persons charged with an attempt to murder or maim, a written medical opinion, or a deposition, may be demanded of a surgeon by a magistrate, in order to justify the detention of prisoners. The law has not defined the meaning of the words, "dangerous to life," or stated to what kind of wound the term dangerous should be applied. This is a point which is left entirely to the professional knowledge of the witness. It is not sufficient on these occasions that a witness should make a naked declaration of the wound being dangerous to life; he must, if called upon, state to the Court satisfactory reasons for this opinion; and those reasons are rigorously inquired into by the counsel for the defence. As a general principle it would not be proper to consider those wounds dangerous to life, in which the danger was not imminent. A wound of a great blood-vessel, or any of the viscera, or a compound fracture with depression of the
bones of the head, must in all instances be regarded as bodily injuries dangerous to life; because in such cases the danger is imminent. Unless timely assistance be rendered, these injuries will most probably prove fatal, and, indeed, they often destroy life in spite of the best surgical treatment. When, however, the danger is remote, as in a puncture or laceration of the hand or foot, which may be followed by tetanus, or in laceration of the scalp, which may be followed by erysipelas, or in penetrating wounds of the orbit, which may be attended by fatal inflammation of the brain or its membranes, the case is somewhat different. Such injuries as these are not directly dangerous to life,—they are only liable to be attended with danger in certain cases; and therefore the medical opinion must be qualified. The law, on these occasions, appears to contemplate the direct and not the future or possible occurrence of danger: if the last view were adopted, it is clear that the most trivial lacerations and punctures might be pronounced dangerous to life; since tetanus or erysipelas proving fatal, has been an occasional consequence of very slight injuries. A difference of opinion will often exist among medical witnesses as to whether a particular wound was or was not dangerous to life. Unanimity can only be expected when the judgment and experience of the witnesses are equal. The rules for forming an opinion in these cases, will, perhaps, be best deduced from the results of the observations of good surgical authorities in relation to injuries of different parts of the body. This will form a subject for examination hereafter.

Dying declarations.—The wound may be of such a nature as to cause death speedily, so that a practitioner may arrive only in time to see the wounded person die. In this case, the dying person may make a statement or declaration as to the circumstances under which the wound was inflicted: he may also mention the names of the parties by whom he was assaulted. This dying declaration or statement, according to the circumstances under which it is made, may become of material importance in the prosecution of a party charged with homicide. It is therefore proper that a practitioner should notice the exact condition of the dying person: whether at the time he makes the statement, he is under the conviction that he must die, either expressed in language or implied by his conduct. According to some authorities, it is not necessary that a man should declare that he believes himself to be dying, in order to render his statement admissible: but he must, at the time of making it, be under the conviction of approaching death. The question respecting the admissibility of a dying declaration was argued in the Court of Exchequer, January, 1845, in the case of Reg. v. Howell, when Alderson, B. said it was not necessary that the deceased should be in articulo mortis, or even that he should think so. It is enough if he thinks he shall die of the sickness under which he labours. (Law Times,
RULES REGARDING DYING DECLARATIONS. 231

Jan. 25, 1845, 317.) When it is made clear to the Court, that all hope of life was lost, the statement will be received as evidence against an accused person; for the law supposes, that in the act of dying, all interest in this world is taken away; and that the near contemplation of death has the same powerful effect upon the mind, as the solemn obligation of an oath. It is presumed that there can be no disposition on the part of a dying person to willfully misrepresent facts, or to state what is false. Much, therefore, often depends on the conduct of a medical practitioner under such circumstances; for the usual method of testing the truth of a statement by cross-examination is, of course, out of the question: it must, if admitted at all, be received as it was made.

It was formerly believed, that if the person at the time of making the statement had still some hope of recovery, it would not be legally admissible. This question was raised in Mr. Seton's case (Reg. v. Pym, Hants Lent Ass., 1846). The deceased had been told by his medical attendant, Dr. Stewart, that there was "not the least hope of recovery." He made a statement, and two or three hours after he asked the surgeon whether he thought he was better; but his (the witness's) conviction was that he then believed that his immediate death was approaching. Counsel for the prisoner objected that this declaration was not admissible. It plainly appeared, from the questions put by the deceased, that he had not given up all hope of recovery, but that he still thought he might recover. (Christie's case, 2 Russ. on Crimes, 754; Bonner's case, ib. 759; and 6 Car. and P. 386; Fagent's case, 7 Car. and P. 238.) "Erle, J.: I think the evidence is admissible. The principle is that a person who speaks with the conviction that his death is fast approaching, speaks under such a sense of responsibility, that the law presumes that he will tell the truth. Here Mr. Seton had a firm belief that his death was fast approaching. Upon the answer of the surgeon, he burst into tears, and thanked the medical men for their exertions. It has, no doubt, been held in some cases that all hope must be given up, but this is now decided not to be necessary. Indeed, if it were so, no declarations could be received, for scarcely a human being could be found, in any circumstances, who would not retain some hope. The law admits these declarations, not because recovery is impossible, but because there is the conviction of approaching death. Mr. Seton was shown to be in this state; the evidence is admissible. The statement was then received." (Law Times, March 21, 1846, 500.) It is not, therefore, necessary, that to render a declaration valid, the person making it must entertain "no hope of recovery." At the Special Commission in Ireland (Jan. 1848, Reg. v. Butler), a declaration was admitted where the words were, that the deceased entertained "little or no hope" of recovery. In the case of Reg. v. Bayley (Exchequer Chambers, Jan. 1857), in which it appeared that the surgeon had given some hope to the
dying person before the declaration was made while the declarant stated that he did not himself believe that he could recover ultimately; its reception was objected to on the part of the prisoners because the surgeon had given the man some hope. He died two days afterwards. Pollock, C. B. ruled that the real belief of the man was the question, and here he had said, notwithstanding the opinion of the surgeon, he believed he could not recover. In the case of Reg. v. Harvey (Exeter Summer Assizes, 1854), the chief evidence against the prisoner consisted of certain statements made by the deceased. They were admitted by Wightman, J. because it appeared clearly from the evidence that when they were made, deceased had expressed an opinion that she should die shortly, and had not changed that opinion. Her whole conduct intimated that she had no hope. It was observed on this occasion that the medical and other witnesses were more desirous of telling the deceased her state, than of ascertaining what her own opinion was.

It is no part of the duty of a medical witness to form a judgment on this important subject. He should give the statement as it was made, and leave the Court to decide upon its admissibility from the circumstances observed by him with respect to the condition of the patient. He should not render himself officious, in extracting information. He should receive what is voluntarily uttered, and, either immediately or on the earliest possible opportunity, write down the statement in the identical words, carefully avoiding his own interpretation of them. On no account should leading questions be put; and any question should be simply confined to the purpose of explaining what may appear ambiguous or contradictory in the declaration. It is well known that when death takes place from violence, especially when this proceeds from hemorrhage or a wound of the head, delirium is apt to supervene, or the intellect of the dying person becomes confused. Under these circumstances, great caution should be used in receiving a declaration, since it may lead to the implication of innocent parties. It is also proper to remark, that the identity of a person is at this time apt to be mistaken; and that it is in general a most injudicious proceeding to take a suspected party before one who is dying, in order that he may be identified. A fatal mistake of this kind was made some years since in London. A woman was maltreated by some men on Kennington Common:—she was taken to St. Thomas's Hospital; and while dying from the effects of the violence, a suspected party was brought before her, as one of the supposed assailants; she stated that he was one of those who had assaulted her. The man was tried, upon her declaration, respecting his identity,—found guilty and executed; but a year after the execution, his innocence was satisfactorily established by the discovery of the real murderers!
WOUNDS CAUSING GRIEVOUS BODILY HARM. 233

In the case of Reg. v. Qualter (Stafford Lent Assizes, 1854), the escape of a criminal was attributed to the neglect of the medical attendant in reference to a dying declaration. The deceased was grossly ill-treated, as it was alleged, by the prisoner and others. He lingered from the 19th June until the 8th of August, 1853, when he died from the injuries received. On his death-bed he made certain statements implicating the prisoner, and upon these the case for the prosecution chiefly rested. Qualter was tried for the murder. The deceased told his wife that he knew he should not recover, but as the declaration against Qualter was made previously, it was of course inadmissible. A similar declaration affecting the prisoner was subsequently made by the deceased to the medical attendant; and it seems that this witness had told the wife that her husband would not recover, but not in the presence of the deceased; hence the declaration made to him was inadmissible, and the prisoner was acquitted. There was a want of proof, in fact, that either declaration had been made by the dying man while he was under the conviction of approaching death. It appears probable that had the surgeon announced to the deceased that he could not recover, or had he made the announcement to the wife in his presence and hearing, the declaration would have been admissible. It is certainly advisable, in all cases when a medical man perceives that the recovery of a wounded person is impossible, that he should take the first opportunity of stating his opinion to the individual, so that the ends of justice may not be defeated by reason of the non-observance of these legal forms. (See also the case of Reg. v. Harvey, Exeter Summer Assizes, 1854.)

Wounds causing grievous bodily harm.—If the witness admit that the wound was not dangerous to life, then he may be required to state whether it was such as to have been capable of producing “grievous bodily harm.” This question is sometimes put, although the most usual practice is to leave it as an inference to be drawn by the jury from the professional description of the injury. These words have a vague signification; but it would perhaps be difficult to substitute for them others less open to objection. They evidently refer to a minor description of offence, and are applied commonly to those injuries which, while they are not actually dangerous to life, may be attended with considerable personal inconvenience, or be in some way detrimental to the health of the wounded party. It is always a question for a jury, whether the intent of the prisoner, in inflicting a wound, was or was not to produce grievous bodily harm. Sometimes the nature or the situation of the wound, as well as the kind of weapon used, will at once explain the intent: so far the medical witness may assist the Court, by giving a plain description of the injury, as well as of the consequences with which it is usually attended. It may happen that the wound itself is not of a very serious nature, and yet the intention of the
prisoner may have been to do grievous bodily harm to the wounded party; or, as in the following case, the injury may be really serious, and yet the prisoner may not have intended to do grievous bodily harm. A man was indicted for feloniously wounding a girl, with intent to do grievous bodily harm. He kicked her in the lower part of her abdomen,—the surgeon described the injury as of the most serious character, and said that at one time he considered the life of the prosecutrix in danger. She was still suffering, and would probably feel the effects of the injury for the rest of her life. The judge, in summing up the case, told the jury that the material question for them to consider was the intent of the prisoner. It was not because serious injury was the result of the prisoner's act, that they were therefore to infer his intention was to do that injury; and they were to judge from all the circumstances, whether, at the time he kicked the prosecutrix, he intended to do her grievous bodily harm, as was imputed to him by the indictment, or whether he was merely guilty of a common assault. He was found guilty of a common assault. (Reg. v. Haynes, Central Criminal Court, September 1847.) In cases of this description, the intent with which the wound was inflicted must be made out by evidence of a non-medical kind. (See also the case of Reg. v. Maslin, Devizes Summer Assizes, 1838.)

These are the principal medico-legal questions connected with wounds when the wounded person is seen while living. We will suppose, however, that the wounded person is found dead, and an examination of the body is required to be made. The most difficult part of the duty of a medical jurist now commences. Among the numerous questions which here present themselves, the first which demands examination is, whether the wound was inflicted on the body before or after death.

CHAPTER XXI.

EXAMINATION OF WOUNDS IN THE DEAD BODY—ALL THE CAVITIES SHOULD BE INSPECTED—ACQUITTALS FROM THE NEGLIGENCE OF THIS RULE—CHARACTERS OF A WOUND INFLECTED DURING LIFE—OF A WOUND MADE AFTER DEATH—EXPERIMENTS ON AMPUTATED LIMBS—CAUTION IN MEDICAL OPINIONS—WOUNDS OR INJURIES UNATTENDED BY HEMORRHAGE—ECCHYMOSIS FROM VIOLENCE—EVIDENCE FROM ECCHYMOSIS—ECCHYMOSIS FROM NATURAL CAUSES—IN THE DEAD BODY—LIVIDITY—VISCERA—EFFECT OF PUTREFACTION—IS ECCHYMOSIS A NECESSARY RESULT OF VIOLENCE?

Examination of wounds.—In examining a wound on a dead body, it is proper to observe its situation, extent, length, breadth,
depth, and direction:—whether there be about it effused blood, either liquid or coagulated, and whether there be ecchymosis in the skin. It should also be ascertained whether the surrounding parts be swollen,—whether adhesive matter or pus be effused,—the edges of the wound gangrenous, or any foreign substances present in it. The wound may be examined by gently introducing into it a bougie, and carrying on the dissection around this instrument, avoiding as much as possible any interference with the external appearances. The preservation of the external form will allow of a comparison being made at any future time between the edges of a wound and a weapon found on a suspected person. Of all these points notes should be taken, either on the spot or immediately afterwards. In the dissection, every muscle, vessel, nerve, or organ involved in the injury should be traced and described. This will enable a witness to answer many subordinate questions that may unexpectedly arise during the inquiry. One other point should be especially attended to. A medical practitioner has frequently contented himself by confining his dissection to the injured part, thinking that on the trial of an accused party the questions of counsel would be limited to the situation and extent of the wound only: but this is a serious mistake. If the cause of death be at all obscure, on no account should the inspection be abandoned until all the important organs and cavities of the body have been closely examined; since it may be affirmed that a natural cause of death might have existed in that organ or cavity which the medical witness had neglected to examine. It rests with the practitioner to disprove the probability thus urged by counsel, but he is now destitute of facts to reason from: legal ingenuity will triumph, the witness will be discomfited, and the prisoner, of whose guilt there may be, morally speaking, but little doubt, will have the benefit of his inattention, and be acquitted by the jury.

In making an inspection of the body, the state of the stomach should not be overlooked. Death may have been apparently caused by violence, and yet really be due to poison. Wildberg was called upon to examine the body of a girl, who died while her father was chastising her for stealing. It was supposed by all that the girl had died from the effects of the violence. On the arms, shoulders, and back, many marks of violent treatment were found; and under some of them blood was extravasated in large quantity. The injuries, although severe, did not however, appear sufficient to account for sudden death. He therefore proceeded to examine the cavities, and on opening the stomach, he found it very much inflamed, and lined with a white powder, which was proved to be arsenic. It turned out that on the theft being detected, the girl had taken arsenic for fear of her father's anger: she vomited during the flogging, and died in slight convulsions. Upon this, Wildberg imputed death to the arsenic,
and the man was discharged. Dr. Geoghegan has communicated to me a case which occurred in Ireland in 1853, in which a gentleman having taken eleven grains of strychnia, threw himself out of a window, and sustained great bodily injury. The surgeon finding so much more spasm than could be accounted for by the violence sustained, discovered the real state of the case from the prisoner’s confession. There was also evidence of the purchase of the poison. The cause of death may be easily assigned in such cases when the circumstances are known; but it is evident that without proper inquiry and great care in conducting examinations after death, the apparent may be sometimes mistaken for the real cause. (For some interesting cases and good practical suggestions on this subject, see Belluc, Cours de Méd. Lég. 148.) Even when there may be no suspicion of poisoning, it will be necessary to observe the state of the stomach and its contents — i.e. to determine whether it contain food, the nature of the food, and the degree to which it may have undergone digestion. In the case of Reg. v. Spicer (Berks Lent Assizes, 1846), the falsehood of one part of the prisoner’s defence was made evident by the examination of the stomach. The deceased was found dead at the foot of a stair. The prisoner stated that after he and his wife had had their dinner, he heard a fall. The woman had died instantaneously, and the fall was heard by neighbours at or near the dinner-hour. Mr. Hooper, the medical witness, found the stomach quite empty; there was no trace of food. It was therefore clear that this part of the prisoner’s story was untrue, as, had the deceased died immediately after dinner, some portion of undigested food would have been found in the organ.

Characters of a wound inflicted during life. — If we find about the wound marks of gangrene, the effusion of adhesive or purulent matter, or if the edges be swollen and enlarged, and cicatization has commenced, it is not only certain that the injury must have been inflicted before death, but that the individual must have lived some time after it was inflicted Marks of this description will not, however, be commonly found when death has taken place within ten or twelve hours from the infliction of the injury. A wound which proves fatal within this period of time will present throughout much the same characters. Thus, supposing it to have been incised, there will be traces of more or less hemorrhage, having chiefly an arterial character, and the blood will be coagulated where it has fallen on surrounding bodies: the edges of the wound are everted, and the muscular and cellular tissue around is deeply reddened by effused blood. Coagula are found adhering to the wound, provided it has not been interfered with. The principal characters of a wound inflicted during life are, then, the following: — 1. Eversion of the edges, owing to vital elasticity of the skin. 2. Abundant hemorrhage, often of
Characters of a wound made after death. — If the wound on a dead body be not made until twelve or fourteen hours have elapsed from the time of death, it cannot be easily mistaken for one produced during life. Either no blood is effused, or it is of a venous character — i.e., it may have proceeded from some divided vein. The blood is commonly liquid, and does not coagulate as it falls on surrounding bodies, like that poured out of a wound in the living. The edges are soft, yielding, and destitute of elasticity; they are therefore in close approximation. The cellular and muscular tissues around are either not infiltrated with blood, or only to a very partial extent. There are no coagula within the wound. In experimenting upon amputated limbs, I have found these characters possessed by a wound after death, even when it had been produced not later than two or three hours after death, although they are best seen when the wound is not made until after the body has lost all its animal heat. In wounds on the dead subject, divided arteries have no marks of blood about them; in the living subject the fatal hemorrhage commonly proceeds from these vessels: hence in a wound on the living, it will be found that the surrounding vessels are empty. The chief characters of a wound after death are, therefore,—1. Absence of copious hemorrhage. 2. If there be hemorrhage, it is exclusively venous. 3. The edges of the wound are close, not everted. 4. There is no sanguineous infiltration in the cellular tissue. 5. There is an absence of coagula. But it may happen that a wound has been inflicted soon after the breath has left the body, and while it was yet warm. The distinction between a wound then made and one made during life is not so well marked as in wounds inflicted at a later period after death. Observations of this kind on the human subject must of course be purely accidental; and there are many obstacles to the performances of experiments on the recently dead. I, therefore, selected limbs immediately after amputation; and there is no reason to suppose that the results obtained in these cases would differ very widely from those derived from experiments made on the entire body.

Wounds on the dead body. — In the first experiment, an incised wound, about three inches in length, was made in the upper part of the calf of the leg; two minutes after its separation from the body, by which the thick muscles of the calf, and the fascia (membrane)
covering the deep-seated layer of the leg, were divided. At the moment that the wound was made, the skin retracted considerably, causing a protrusion of the adipose substance beneath: the quantity of blood which escaped was small,—the cellular membrane, by its sudden protrusion forwards, seeming mechanically to prevent its exit. The wound was examined after the lapse of twenty-four hours: the edges were red, bloody, and everted; the skin was not in the least degree swollen, but merely somewhat flaccid. On separating the edges, a small quantity of fluid blood escaped, but no coagula were seen adhering to the muscles. At the bottom of the wound, however, and in close contact with the fascia, was a small quantity of coagulated blood; but the coagula were so loose as readily to break down under the finger. In a second experiment, ten minutes after the separation of the member from the body, an incision of similar extent was made on the outer side of the leg, penetrating through the peronei into the flexor longus pollicis of the deep-seated layer of muscles. In this case the skin appeared to have already lost its elasticity, for the edges of the wound became but very slightly everted, and scarcely any blood escaped from it. On examining the leg twenty-four hours afterwards, the edges of the incision were pale, and perfectly collapsed, presenting none of the characters of a wound inflicted during life. Still at the bottom of the wound, and inclosed by the divided muscular fibres, there were some coagula of blood; but these were certainly fewer than in the former experiment. A portion of liquid blood had evidently escaped owing to the leg having been moved. Other experiments were performed at a still later period after the removal of the limbs; and it was found that in proportion to the length of time suffered to elapse before the production of the wound, so were the appearances less distinctly marked: that is to say, the less likely were they to be confounded with similar injuries inflicted upon the living body. When the incised wound was not made until two or three hours after the removal of the limb, although a small quantity of liquid blood was effused, no coagula were found.

It is necessary to remember that, when an incised wound is the cause of death, the person dies either immediately, in which case there is a most abundant hemorrhage from the wounded organ or some large vessel,—or he dies after some time, in which case, as the wound continues to bleed during the time that he survives, the longer he lives the more copious will be the effusion of blood. In a wound inflicted after death and while the body is warm, nothing of this kind is observed. Unless the weapon injure one of the large veins, the hemorrhage is always slight, so that the quantity of blood lost may assist us in determining whether the wound was made during life or after death. When the body has been moved, and all marks of blood effaced by washing,
rules of this kind cannot serve a medical witness:—the time at which the wound was actually inflicted must then be deduced from other circumstances. In the case of Greensacre, who was tried in 1837 for the murder and mutilation of a female, this formed a material part of the medical evidence. The head of the deceased had been severed from the body, and the question was, whether this severance had taken place during life or after death. The prisoner alleged in his defence that it was after death; but the medical evidence went to establish that the head must have been cut off while the woman was living, but probably after she had been rendered insensible by a blow on that part, the marks of which were plainly visible. This medical opinion was founded on two circumstances. The muscles of the neck were retracted, and the head was completely drained of its blood, showing that a most copious and abundant flow must have ensued at the time of separation; and therefore indicating that the circulation was probably going on at that time. On cutting off a head after death a small quantity of blood may escape from the jugular veins: but this soon ceases, and the quantity lost is insufficient to affect materially the contents of the cerebral vessels. The chief medical witness, Mr. Girdwood, expressed himself with proper caution, by stating, in answer to a question from the judge, that all the wounds in the neck had been inflicted either during life or very shortly after death, while the body still preserved its warmth. The circumstantial evidence tended to show that the deceased was first stunned, and that her head was cut off while she was in a state of stupor.

In any case in which it is doubtful whether a wound was inflicted on a living or dead body, it will be proper to adopt the same cautious mode of expressing a medical opinion; since it must be remembered there are no decisive characters by which wounds of the kind referred to can be distinguished; and a medical witness is as likely to be wrong as right in selecting either hypothesis. It is a considerable step in evidence, when we are able to assert, that a particular wound, found on a dead body, must have been inflicted either during life or immediately after death; for it can scarcely be supposed that in a case calling for criminal investigation, any one but a murderer would think of inflicting upon a body immediately after death a wound which would assuredly have produced fatal effects had the same person received it while living. So soon as such an opinion can be safely expressed by a witness, circumstantial evidence will often make up for that which may be, medically speaking, a matter of uncertainty.

Wounds or injuries unattended by hemorrhage.—The copious effusion of blood has been set down as a well-marked character of a severe wound received during life; but this observation applies chiefly to certain wounds,—i.e. to cuts and stabs. Lac-
rated and contused wounds of a severe kind are not always accompanied by much haemorrhage, even when a large blood-vessel happens to be implicated. It is well known, that a whole member has been torn from the trunk, and that little blood has been lost; but in such cases coagula are commonly found adhering to the separated parts,—a character which indicates that the wound was inflicted either during life or soon after death. When a lacerated or contused wound involves a highly vascular part, although no large blood-vessel may be implicated, it is liable to cause death by loss of blood. In a case tried at the Liverpool Winter Assizes, 1847 (Reg. v. Cauley), the prisoner was charged with having caused the death of his wife by kicking her in the lower part of the abdomen. Copious bleeding followed, and in spite of medical assistance the woman died very shortly afterwards, evidently from exhaustion produced by the loss of blood. It was stated in evidence that there was no external laceration, but an examination of the body showed that a contused wound (of the genitals) had been produced internally, and had given rise to fatal bleeding. There is nothing at all remarkable in such a result, considering the great vascularity of these parts in the female.

Ecchymosis from violence.—Contusions and contused wounds are commonly accompanied by a discolouration of the surrounding skin, to which the term ecchymosis is applied. The subject of ecchymosis is of considerable importance in legal medicine, since it has often given rise to numerous difficulties and complicated questions. It consists essentially in the extravasation or effusion of blood from ruptured vessels into the surrounding cellular texture. An ecchymosis is in general superficial, affecting only the layers of the skin, and showing itself externally, either immediately or in the course of a short time, in the form of a deep blue or livid red patch. According to Dr. Chowne, the former colour is met with in the ecchymosis slowly produced; while that which is the immediate result of violence is red or livid red. In some instances the ecchymosis is deep-seated,—the blood being poured out among the muscles and beneath the fascia; its extent cannot then be so readily determined by the external discolouration, for this is commonly slight, and it appears only after the lapse of some hours, or even two or three days. Sometimes the ecchymosis shows itself not over the immediate seat of injury or around it, but at some distance from it. This is a matter of importance to a medical jurist, since he might be led to suppose that the violence had been applied to the discoloured portion of skin, whereas the extravasation may have been produced by what has been called contre-coup, or counter-stroke. Dr. Chowne met with an instance in which a young man received a severe bruise on the inner side of the ankle. In two days, ecchymosis appeared around the outer ankle. The term contre-coup is, how-
ever, inappropriate: since the blood will diffuse itself wherever it meets with the least resistance, and the layers of skin in the part struck, may become so condensed by the blow, that the blood is diffused in the cellular membrane of the adjoining parts. Mr. Syme met with a case in which a compound fracture of theibia, about one-third down, was produced by the wheel of a carriage passing over the leg of a woman. There was no ecchymosis around the seat of injury; but after some days, the skin of the knee and lower part of the thigh became ecchymosed. (Ed. Med. and Surg. Journ. Oct. 1836.) It is proper to mention, that ecchymosis may sometimes proceed from causes irrespective of the direct application of violence to the skin. In some muscular exertions—the act of vomiting, and many other conscious, may give rise to a rupture of the minute vessels, and to an effusion of blood in parts which have been stretched or compressed. I have known it to have been produced to a great extent around the knee without any blow, from the stretching of the ligament of the kneecap in an individual who was trying to save himself from suddenly falling forwards with his knee bent under him. Such cases are commonly recognised; but there being no mark of mechanical injury about the part,—the seat is smooth and unabraded.

Ecchymosis strictly signifies the effusion or pouring out of blood; but the effusion may be so deep-seated as not to present any external discoloration (ecchymosis). It is scarcely necessary to observe that the term effusion applies to internal as well as to external hemorrhage, and those that be borne in mind medical testimony may be wholly misunderstood. Dr. Chalmers states that some years ago, on a trial in the High Court of Justiciary at Edinburgh, the public prosecutor attempted to prove that the person assailed had been wounded to the effusion of blood, which, according to the law of Scotland, is an aggravation of guilt in such cases. When the principal medical witness was examined as to the injuries inflicted, he was asked whether any blood had been effused: and he replied that a good deal must have been effused. But he meant effusion of tarax; under the skin, constituting the contusion or bruise described, while the Court at first received the answer as implying that there had been a considerable loss of blood from a wound externally. The ambiguity was, however, detected (Edinburgh Monthly Journal, Nov. 1851, p. 454). This case shows the importance of medical evidence being given in language intelligible to all. At the same time the amount of personal injury inflicted is not at all dependent on the external effusion of blood. The assault may be of the most grievous kind, and yet no blood be effused through a wound in the skin.

It is of importance to know that violence inflicted on a living body may not show itself under the form of ecchymosis until
after death. A case of this kind was communicated to me by Mr. J. Steavenson. A man received from behind several kicks on the lower part of the abdomen, which caused a rupture of the bladder, and death by peritonitis. He died in about thirty-five hours; but there was no ecchymosis in the seat of the blows, i.e. the pubic and lumbar regions, until after death. Dr. Hinze met with a case of suicidal hanging, in which it was observed that ecchymosis appeared in the course of the cord only after death. (See HANGING, post.) It has been remarked by Devereux that ecchymoses are often concealed on the bodies of the drowned, when first removed from water, owing to the sodden state of the skin; they may become apparent only after the body has been exposed for some days, and the water has evaporated.

A medical jurist must guard against the error of supposing that when a blow has been inflicted on a living person, it is necessary that the individual who is maltreated should survive for a long period in order that ecchymosis should be produced. Among numerous instances proving the contrary, the case of the Duchess of Praslin (August 1847) may be mentioned. This lady, who was assassinated by her husband, was attacked while asleep in bed. The number of wounds on her person (thirty) showed that there had been a mortal struggle, which, however, could not have lasted more than half an hour. Yet, on inspection, there were the marks of numerous ecchymoses, which had resulted from the violent use of a bruising instrument. (Ann. d'Hyg. 1847, ii. 377.)

Changes of colour.—The changes which sometimes take place in the colour of an ecchymosed spot are worthy of attention, since they will serve to aid the witness in giving an opinion as to the probable time at which a contusion had been inflicted. After a certain period, commonly in eighteen or twenty-four hours, the blue or livid margin of the spot is observed to become lighter; it acquires a violet tint, and before its final disappearance it passes successively through shades of a green, yellow, and lemon colour. During this time, the spot is much increased in extent, but the central portion of the ecchymosis is always darker than the circumference. These changes have been referred by Chaussier and others to the gradual dilution of the serous portion of the extravasated blood by the fluid of the cellular membrane, and its slow and uniform dispersion throughout the cells. The colour is finally entirely removed by the absorption of the extravasated blood. The extent and situation of the ecchymosis, the degree of violence by which it has been produced, as well as the age and state of health of the person, are so many circumstances which may influence the progress of these phenomena. Thus an ecchymosis is longer in disappearing in the old than in the young. Mr. Watson, of Edinburgh, found effused blood in an ecchymosis in an old
person, five weeks after the infliction of the injury. Where the cellular membrane is dense, the ecchymosis, ceteris paribus, is not so rapidly formed; nor, when formed, do the above changes take place in it so speedily as when the blood is effused into a loose portion of membrane like that surrounding the eye or existing in the scrotum. In some instances an ecchymosis has been observed to disappear without undergoing changes of colour at its margin. On examining an ecchymosed portion of skin which has suffered from a severe contusion, we find that the discolouration affects more or less the whole substance of the true skin, as well as the cellular membrane beneath: it is necessary to remember this in forming our diagnosis.

Evidence from the form of an ecchymosis.—It not unfrequently happens that the ecchymosis produced by a contusion will assume a form indicative of the means by which the violence was offered. In hanging, the impression caused by the cord on the neck is sometimes ecchymosed, and indicates its course with precision; —so also in strangulation, when the fingers have been violently applied to the fore part of the neck, the indentations produced may serve to point out the manner in which life was destroyed. A case is mentioned by Starkie, which shows that the form of an ecchymosis may occasionally furnish very strong presumptive evidence against an accused party. In an attempt at murder, the prosecutor, in his own defence, struck the assassin violently in the face with the key of the house-door,—this being the only weapon he had near at hand. The ecchymosis which followed this contusion corresponded in the impression produced on the face to the wards of the key; and it was chiefly through this very singular and unexpected source of evidence, that the assassin was afterwards identified and brought to trial. (Law of Evidence, Vol. i. art. Circ. Ev.)

Contusions on the dead.—For our knowledge of the effects of contusions on the recently dead body, we are chiefly indebted to Dr. Christison. This gentleman found that blows inflicted two hours after death, will give rise to appearances on the skin similar to those which result from blows inflicted recently before death. The livid discolouration thus produced generally arose from an effusion of the thinnest possible layer of the fluid part of the blood on the outer surface of the true skin, but sometimes also from an effusion of blood into a perceptible stratum of the true skin itself. He likewise found that dark fluid blood might even be effused into the subcutaneous cellular tissue in the seat of the discolourations, so as to blacken or redden the membranous partitions of the adipose cells; but this last effusion was never extensive. From this, then, it follows, that by trusting to external appearance only, contusions made soon after death may be easily confounded with those which have been produced by violence shortly before death.

If a contusion has been caused some time before death, there will be swelling of the part, and probably also certain changes of colour in the ecchymosed patch, in either of which cases there will commonly be no difficulty in forming an opinion. Although ecchymosis, or an appearance analogous to it, may be produced after death, the changes in colour are then met with only under very peculiar circumstances, to be presently mentioned. If the blood found beneath an ecchymosed spot be in the state of coagulum, this will afford a remote presumption of its having been effused during life, although, in fact, it only proves that the effusion must have taken place before death, or very soon after it; and the experiments related, in speaking of incised wounds, show that the blood effused from a wound ten minutes after death may still be found in a coagulated state. Again, the circumstance of the blood effused under a contused wound being liquid, is not to be considered as a proof that the effusion did not take place during life; for sometimes, as in death from a sudden and violent shock to the nervous system, or in cases of rupture of the heart, the effused blood may not coagulate after death. Blood effused into the spinal canal during life is often fluid: and it is well known that the blood may be found coagulated in some parts of the body, while it remains uncoagulated in others. There is reason to believe that the blood coagulates more slowly in the dead body than in a vessel into which it has been drawn during life or after death. The blood may remain fluid in the dead body from four to eight, and, according to Donné, twelve hours after death (Cours de Microscopic, 52). It rarely begins to coagulate until after a lapse of four hours; but if drawn from a blood vessel and exposed to air, it would probably coagulate in a few minutes after its removal.

In general those contusions which have been produced during life, and in which the effused blood remains liquid, may be recognised by the extent of the effusion. If, under the ecchymosed part, we find a large quantity of liquid blood, and the seat of injury is so situated that the blood could not have become infiltrated into it, and at the same time there is no ruptured vein from which it might have flowed, we may confidently pronounce that the effusion must have preceded death. In a dead body, a contusion would cause but little extravasation, unless a vein of very large size were torn through. The sign which is most satisfactory as a criterion, in the opinion of Dr. Christison, is, however, the following:—In a contusion inflicted during life, the ecchymosed portion of cutis (true skin) is generally dark and much discoloured by the infiltration of blood throughout its whole thickness; the skin at the same time is increased in firmness and tenacity. This is not, however, a uniform consequence of a contusion during life; for a blow may cause effusion of blood beneath the skin without affecting the cutis in the manner
stated. The state of the skin here described, cannot, however, be produced by a contusion on a dead subject; although it is questionable whether it might not be produced if the contusion were inflicted a few minutes after death. As it is, the value of this sign is somewhat circumscribed,—it is not always produced on the living,—it might be possibly produced on the recently dead; so that when it does not exist, we must look for other differential marks; and when it does exist, we ought to satisfy ourselves that the contusion was not inflicted recently after death.

The period at which such injuries cease to resemble each other, has not been fixed with any degree of precision; but, as in the case of incised wounds, it would seem that there is little danger of confounding them, when a contusion has not been inflicted on the dead subject until after the disappearance of animal heat and the commencement of cadaverous rigidity! Dr. Christison found that sometimes the appearance of contusions could hardly be produced on the dead body two hours after death; at others they may be slightly caused after three hours and a quarter; but this period is very near the extreme limit. Whenever the warmth of the body and the laxity of the muscles are not considerable at the time the blow is inflicted, the appearance of contusions during life cannot be distinctly produced. It is, therefore, only on the trunk that, even in the most favourable state of the body,—namely, when the blood remains altogether liquid,—that a mark resembling a contusion on the living body can be produced so late as two hours after death. (Ed. Med. and Surg. Jour. No. 99, p. 247. et seq.) Notwithstanding these very satisfactory results, it will be seen, that from the moment of death until after a lapse of two hours, contusions may be followed by appearances on the dead body almost identical with those observed on the living. The earliest period after death in which an experiment was tried on the human subject, was one hour and three-quarters: in this case the similarity was so strong, that we may infer, if the experiments had been performed within half an hour, or even an hour after dissolution, it would have been very difficult to say whether the blow producing the discoloration had been inflicted on the body before or after death. Dr. Christison's experiments lead to the conclusion that severe blows inflicted on a recently dead body, produce no greater degree of ecchymosis or cutaneous discoloration than slight blows inflicted before death. Assuming that the great extent of an ecchymosis would in all cases serve to show that the violence producing it had been inflicted during life, it must be remembered that the importance of these facts, in relation to medical evidence, is not affected by the extent of the discoloration. It may be just as necessary to have a positive opinion on the origin of a slight, as on the origin of an extensive bruise. Trivial ecchymoses, as in cases of strangulation, if they
can be certainly pronounced vital, may make all the difference between the acquittal or conviction of a person charged with murder. Again, slight ecchymosis on the bodies of the drowned may excite a suspicion of strangulation and subsequent immersion of the body in water. This question is quite irrespective of the extent of the ecchymosis,—the great point for the medical witness to consider is, whether it occurred during life or after death. Cases in which a mistake might easily have arisen, will be related in speaking of marks of violence on the drowned.

The practical inference, then, is, that these discolourations after death are liable to be mistaken for marks of violence to the living body. An instance has been communicated to me, on respectable authority, in which, for the sake of experiment, blows with a stick were inflicted on the recently dead body of a female, while still warm. The body was afterwards accidentally seen by non-professional persons, who were not aware of the performance of these experiments, and so strong was the impression, from the appearances, that the deceased had been maltreated during life, that a judicial inquiry was actually instituted, when the circumstances were satisfactorily explained. The fact, therefore, that severe blows after death resemble slight blows during life, is, in a practical view, unimportant. It does not aid our diagnosis, nor prevent serious mistakes from occurring.

**Ecchymosis from natural causes in the living.**—There are certain conditions of the body in which ecchymosed marks are found on the skin, that a witness must be careful not to confound with ecchymosis arising from violence. First with regard to the living body,—in very aged persons, it is not unusual to find the legs and feet covered with livid patches, sometimes of considerable uniformity of colour, at others very much mottled. These discolorations, which, after death, might be mistaken for ecchymosis from violence, arise from the languor of the capillary circulation in such subjects: the blood with difficulty finds its way through the venous capillaries, and the marks are commonly observed on the lower parts of the body, because they are far removed from the centre of circulation, and the blood has to rise contrary to the law of gravity. This is the condition which has been denominated by Andrä, asthenic hyperemia. (Andrä, Anat. Pathol. t. i. p. 40.) Similar discolorations are sometimes met with on the bodies of those who have died from scurvy, typhus, and other adynamic diseases. In persons severely affected with scurvy, it is well known that the slightest pressure on any part of the skin will suffice to produce a spot resembling the ecchymosis of violence, and arising like it from a rupture of minute cutaneous vessels; but the extravasation of blood, which causes the discoloration, is commonly confined to the superficial layers of the true skin. These spots, under certain states of the system, occur spontaneously, and often cover the body to a great extent:
when small, they take the name of petechie; but when extensive, in which case they bear a very close resemblance to the ecchymosis of violence, they constitute the chief pathognomonic character of the disease termed purpura. To all these effusions of blood in the living body, the term Sugillation (from sugillatio, a black mark) has been applied. Some medical jurists have attempted to draw a distinction between ecchymosis and sugillation: thus it is said: ecchymosis proceeds from external, sugillation from internal causes,—ecchymosis is confined to the marks which occur in the living body, sugillation to those which occur in the dead:—in ecchymosis the vessels are ruptured, in sugillation there is mere congestion;—again, some have considered that ecchymosis and sugillation might take place both in the living and in the dead. From this statement, it appears impossible to give a consistent definition of the meaning of either of these terms; but it is altogether unnecessary to make the attempt, for the error, after all, consists in the introduction of a superfluity of words to express a simple condition of the body, depending on different causes. Why, according to the view taken by Chaussier, an ecchymosis should not also be called a sugillation, it is difficult to say: for so far as we are bound by a comparison of the definitions above given by the usual application of these words, the terms are equally appropriate. I would advise a medical jurist to avoid the use of the term sugillation, if by employing it he considers that he is speaking of a condition essentially different from ecchymosis. The most important point to attend to, is to distinguish those ecchymoses in the living body arising from infirmity or disease, from those which have their origin from violence. In regard to the spots on the legs of old persons, the appearance of the subject, and their general extent, enveloping, as they often do, the whole circumference of the leg, must suffice to establish a clear distinction. In distinguishing the spots of purpura, a difficulty may sometimes exist; but here also the appearance of the subject, the general diffusion of the spots over the whole of the body, and their simultaneous existence on the mucous membrane of the throat and alimentary canal, cannot fail to point out that they originate from some other cause than violence. In the living, these spots have been observed to undergo the same changes of colour as the true ecchymosis of violence. It has been alleged, on the authority of Zacchias, one of the early writers on medical jurisprudence, that a distinction is obtained in these cases after death by a dissection of the part. According to this authority, in what is termed sugillation, i.e. the ecchymosis of disease, the blood is stated to be fluid, while in the ecchymosis of violence it is described as being in a thick and concrete state. In the remarks already made respecting contusions, facts have been mentioned which show that such a distinction is inadmissible; neither the state of the blood nor its situation will
alone suffice to determine the question. Although it has been usual to describe the echymosis of disease as being due to a superficial extravasation on the true skin, yet certain cases recorded by pathologists prove that in purpura or scurvy the discoloration may occasionally extend through the whole substance of the skin to the fatty tissue beneath.

**Echymosis in the dead body. Lividity.**—Echymosis may present itself in various forms on the skin of a dead subject. The first form, when it occurs, is almost an immediate consequence of death, but it is not fully developed until the body has cooled. It is commonly called *Cadaveric lividity*. It presents itself in diffused patches of very great extent, sometimes covering the whole of the fore part of the chest and abdomen, at other times the lateral regions of the back. The upper or lower extremities, either on their internal or external surfaces, or on their whole circumference, are often thus completely echymosed. The colour is sometimes purple, at others livid, and often mottled in interspaces; but it is commonly well-defined in its extent by the whiteness of the surrounding skin. This form of echymosis is generally seen on the bodies of those who die suddenly or by a violent death, as well as in individuals who perish from apoplexy, or who are hanged or suffocated. When the skin is divided, the colour is found to be confined to the upper surface of the cutis, and never to extend through it. This discolouration is ascribed to the congestion which takes place in the capillary system at the moment of death, in subjects that are full of blood. It is rarely seen in the bodies of those who have died from profuse bleeding— the skin is in these cases commonly pallid. The circumstances under which it occurs, and the characters above described, distinguish it from the echymosis of violence. Its existence on the dead body must be regarded as a sign of the vigour and activity of the circulation at the moment of death, and generally as a mark of death having taken place suddenly. It might seem improper to call this which has been described as a mere capillary congestion, "echymosis," this word signifying effusion; but the term *sugillation* has been so vaguely employed by different writers, that I think the former preferable to the latter, in spite of the apparent inconsistency of its application to every variety of cutaneous discoloration. (See Henke, Zeitschrift der S. A., 1844, i. 199.)

**Vibices.**—Sometimes, instead of seeing this cadaveric lividity diffused in large patches over the skin, it will be disposed in stripes which traverse and intersect each other in all directions, and often cover the whole of the body. These marks, which vary from a scarlet to a dark red or livid hue, have been supposed to resemble those produced on the skin by the act of scourging or flagellation. On this account they have been called by some writers *vibices*. Sometimes the body is completely covered with
them,—they are often of considerable length, and pass in a very symmetrical but occasionally tortuous course; they are chiefly observed about the sides, the upper part of the shoulders, and back. In meeting with this appearance for the first time on a subject, an individual, unacquainted with its nature, might look upon it as a strong proof of violent treatment during life, especially in a case of suspected violence; but the practitioner will distinguish it readily, by the uninjured state of the cuticle and the superficial nature of the discoloration, from those marks of violence which it is considered to resemble. In general, it appears to be produced by the wrapping of a body in a sheet or other covering soon after death, and allowing it to cool while thus wrapped up; even if a subject be allowed to cool merely with the clothes covering it, these peculiar marks will often be seen. In many cases they exist only on the back, and here they are to be ascribed to the pressure produced by the irregularities or folds in the sheet on which the body has been lying. The capillaries, it is to be observed, are always congested in or near those parts of the skin which are exposed to the least pressure.

A few years since I saw a well-marked case of vibices, in which the suspicion was so strong that violence had been used to the deceased, that a coroner’s inquest took place. The fore part of the body was covered with stripes, which were of a red and livid colour; they seemed to correspond exactly to the folds of a sheet drawn tightly across the chest; and it was subsequently ascertained that the body of the deceased had been treated in this manner after death. The blood was superficially diffused, and the cuticle uninjured. The circumstances above mentioned at once satisfactorily explained the cause of the appearance. These vibices or stripes, like the cadaveric lividity already described, are commonly seen in plethoric subjects; they also indicate great vigour of circulation at the moment of death.

But lividity sometimes presents itself in a more deceptive form than in either of the instances just mentioned; as in the following case. A man, aged thirty-three, died suddenly from disease of the heart. Eighteen hours after death, the body was examined, and the skin was then found to be covered in different parts with patches of ecchymosis, varying in size from small spots to others of several inches in diameter. These patches were evidently due to simple lividity, although they closely simulated marks of violence produced during life. On cutting into them the layers of the cutis as well as the cellular tissue beneath were throughout reddened by a congestion of blood. There was no decided extravasation, but small rounded semi-coagulated masses oozed out from the cells on slight pressure. There was another extraordinary, and, so far as I know, a perfectly unexampled circumstance, in which these patches of lividity resembled the ecchymosis of violence produced during life. Around many of
them there was a wide border or ring of straw colour, with various shades of green, precisely similar to those witnessed in the disappearance of an ecchymosis from the living subject. By all medical jurists, it has been hitherto laid down as a positive rule, that these rings of colour when not depending on putrefaction, are peculiar to an ecchymosis of the living body, and are never seen in an ecchymosis taking place spontaneously after death. The occurrence of this case shows with what caution general rules should be framed for medico-legal practice. Had the body of this person been found lying dead exposed on a high road, and had it been proved that another man was seen quarrelling with him, it is easy to imagine that a very unfavourable medical opinion might have been expressed against the party accused of the violence. This kind of ecchymosis could only have been distinguished from that of violence during life, by the unruffled state of the skin, and the very slight extravasation of blood compared with the extent of the ecchymosed surface. It is worthy of note, also, that the principal seat of the ecchymosis was in those parts which were recumbent or depending. The formation of the coloured zones around some of the patches of lividity was fully explained by the fact of the man having laboured under general dropsy. The serum effused in the cells here acted upon and diluted the blood as it became extravasated; and diffused it around, much in the same way as the serous exhalation of the cellular membrane acts on the blood effused in the living body. A wax model of this remarkable appearance is preserved in the museum of Guy's Hospital, and is well worthy of inspection.

Effects of Putrefaction.—Another form of ecchymosis observed in the dead body, is that which occurs some time after death. This appears to proceed from an infiltration of blood into the depending parts of the body, and to be a result of incipient putrefaction. They who are much engaged in inspections are well aware that the skin of the back, especially that covering the loin and buttocks, often presents irregular discolorations resembling ecchymosis. The skin of the back of the head is a well-known seat of this form of ecchymosis. On cutting into the skin of any of these parts, the whole of the cutis is found to be more or less discoloured, and the fatty tissue is filled with a bloody serum, which readily escapes. In proportion as putrefaction advances, the discoloration becomes greater, passing from a dark red to a green colour. The general characters of this kind of ecchymosis are so well-marked, that it cannot easily be confounded with the ecchymosis of violence. The parts of the body in which it is known to occur as well as the state of the body, are circumstances which distinguish it from all the other forms described. This variety of ecchymosis is also termed sugillation by some medical jurists. (On the subject of Ecchymosis, see Ann. d'Hyg. 1838, ii. 383.)
ECCHYMOSIS NOT A NECESSARY RESULT OF VIOLENCE. 251

Is ecchymosis a necessary result of violence? — This is an important medico-legal question, which has often created great difficulty to medical witnesses. It has been repeatedly asserted in Courts of law, that no severe blow could have been inflicted on a deceased person in consequence of the absence of ecchymosis from the part struck; but we shall see that this assertion is entirely opposed to well-ascertained facts. However true the statement may be that severe contusions are commonly followed by ecchymosis, it is open to numerous exceptions; and unless these are known to a practitioner, his evidence may mislead the Court. The presence of ecchymosis is commonly presumptive evidence of the infliction of violence; but its absence does not negative this presumption.

It was long since remarked by Portal, that the spleen had been found ruptured from blows or falls, without any ecchymosis or abrasion of the skin appearing in the region struck. This has been more recently observed in respect to ruptures of the stomach, intestines, and urinary bladder, from violence directly applied to the abdomen. Portal supposed that the mechanical impulse was simply transferred through the supple parietes of the abdominal cavity to the viscera behind, as in the striking of a bladder filled with water. Whether this be the true explanation or not, it is quite certain that the small vessels of the skin often escape rupture from a sharp blow, so that their contents are not extravasated.

A case is reported by Henke, in which a labouring man died some hours after fighting with another; and on inspection of the body the peritoneum was found extensively inflamed owing to an escape of the contents of the small intestines, which had been ruptured to a considerable extent. There was, however, no ecchymosis or mark on the skin externally, and the medical inspectors were inclined to affirm, contrary in this case to direct evidence, that no blow could have been struck; but others were appealed to, who at once admitted that the laceration of the intestines might have been caused by a blow, even although there was no appearance of violence externally. Mr. Watson states, that a girl, aged nine, received a smart blow upon the abdomen from a stone. She immediately complained of great pain; collapse ensued, and she died in twenty-one hours. On inspection there was no mark of injury externally; but the ileum was found ruptured, its contents extravasated, and the peritoneum extensively inflamed. (On Homicide, 187.) Dr. Williamson, of Leith, met with a case where a man received a kick on the abdomen from a horse:—he died in thirty hours from peritonitis. The ileum was found to have been torn completely across in its lower third. There was not the slightest trace of ecchymosis externally; and this fact is the more remarkable, since the blow was here struck by a somewhat angular or pointed body—the hoof of a horse. (Med. Gaz. May 1840.) In a fatal railway
accident which occurred at Leicester in November 1854, there were no marks of external violence on the head, but Mr. Macaulay found a laceration of the left hemisphere of the brain with effusion of a large quantity of blood which had coagulated.

Many cases might be adduced in support of the proposition that ecchymosis is not a necessary or constant result of a severe contusion; but those already related sufficiently establish the fact. This medico-legal question frequently arises in cases in which the bladder is ruptured, as, owing to the general absence of marks of violence, it is often alleged in defence that no blow or kick could have been inflicted on this part of the abdomen. The incorrectness of this view will be apparent by a reference to cases of ruptured bladder related in another part of this work. In the meantime, I am indebted to Dr. Easton of Glasgow, a gentleman who has deservedly acquired a high reputation for his medico-legal knowledge, for a recent case of rupture of the liver, under circumstances in which the appearance of ecchymosis would have been generally expected as a result of violence. In January 1852, a woman, aged 75, was run down by a cab in the streets of Glasgow, and died in less than half an hour. No ecchymosis existed, although four ribs on the right side of the chest at the lower part were broken, and the liver was ruptured in two places longitudinally, and throughout the entire length of its anterior and convex surface. The laceration of this organ had not been caused by the fractured ends of the ribs penetrating downwards, for of these there was no displacement, but the organ seemed to have burst in consequence of the heavy compression to which it had been subjected, which had not been sufficient, however, to occasion discolouration of the skin externally. Admitting, then, that the most severe internal ruptures and lacerations may occur without being necessarily attended by ecchymosis, it is scarcely necessary to observe that when the facts of the case are imperfectly known, we must take care not to assign ruptures of organs (e.g., the heart, large vessels, or the bladder,) from natural causes to external violence. Ruptures from natural causes do not occur unless the organs be in a diseased condition.

An illustration of the fact that murderous violence may be produced by blows on a body without leaving any external marks, is furnished by a case recently tried in Scotland (Cuming for the murder of his wife, Dec. 19, 1853). The woman died from a severe injury to the head; but she chiefly complained of great pain in one of her breasts, and in her chest on that side. From her statement it appears that the prisoner had used great violence to this part of her body; yet on a careful examination, during life and after death, there were no marks of ecchymosis or contusion.
CHAPTER XXII.

Evidence of the use of a weapon.—It sometimes happens on a criminal investigation, that a weapon is presented to a medical witness; and he is required to say whether the wound, found on the body of a person, was produced by it. On the certainty of a weapon having been used, it is not uncommon for prisoners, even when found guilty upon the clearest evidence, to declare that no weapon was employed by them, but that the wound had been occasioned by accidental circumstances. A witness should remember, that he is seldom in a position to swear that a particular weapon produced at a trial, must have been used by the prisoner:—he is only justified in saying, that the wound was caused either by it or one similar to it. In reference to this subject, Schwörer relates the following case. A man was stabbed by another in the face, and a knife, with the blade entire, was brought forward as circumstantial evidence against him,—the surgeon having declared that the wound must have been caused by this knife. The wounded person recovered; but a year afterwards an abscess formed in the face, and the broken point of the real weapon was discharged from it. The wound could not therefore have been produced by the knife which was brought forward as evidence against the prisoner at the trial. (Lehre von dem Kindermorde.) Although the criminality of the act is not lessened or impugned by an occurrence of this kind, it is advisable that such mistakes should be avoided by the use of proper caution on the part of a witness. (On this question, see the case of Renaud, by Dr. Boys de Loury, Ann. d'Hyg. 1839, xi. 170. As to what is a weapon, see Henke, Zeitschrift der S. A. 1844, i. 67.)

Characters of wounds produced by weapons.—Let us now suppose that no weapon is discovered; and that the opinion of a witness is to be founded only on an examination of the wound. It is right for him to know that on all criminal trials, considerable importance is attached by the law to the fact of a wound having been caused by the use of a weapon; since this often implies malice, and in most cases a greater desire to injure the party assaulted, than the mere employment of manual force. Some wounds at once indicate that they must have been produced by weapons. This is the case with cuts and stabs.

Incised wounds.—In incised wounds, the sharpness of the instrument may be inferred by the cleanliness and regularity with
which the edges are cut: in stabs, also, the form and depth of the wound will often indicate the kind of weapon employed. Stabs sometimes have the characters of incised punctures, one or both extremities of the wound being cleanly cut, according to whether the weapon was single or double-edged. Dupuytren has remarked, that such stabs, owing to the elasticity of the skin, are apparently smaller than the weapon—a point to be remembered in instituting a comparison between the size of the wound and the instrument. A lateral motion of the weapon may, however, cause a considerable enlargement of the wound. (See case, Ann. d’Hvg. 1847, i. 400.) When a stab has traversed the body, the entrance-aperture is commonly larger than the aperture of exit; and its edges, contrary to what might be supposed, are sometimes everted, owing to the rapid withdrawal of the instrument. That facts of this kind should be available as evidence, it is necessary that the body should be seen soon after the infliction of a wound, and before there has been any interference with it.

_Punctured wounds._—It is important to notice whether the edges of a punctured wound be lacerated and irregular, or incised; because it may be alleged in the defence, that the wound was produced by a fall on some substance capable of producing an injury somewhat resembling it. In a case that occurred to Mr. Watson, a deeply penetrating wound on the genital organs of the deceased, which had evidently caused the woman’s death, was ascribed by the prisoners charged with the murder, to her having fallen on some broken glass; but it was proved that the edges of the wound were bounded everywhere by clean incisions, which rendered this defence inconsistent, if not impossible. I have known a similar defence made on two other occasions, where the cases came to trial. In one, a man struck the prosecutor, and knocked him against a window. On examination, there were three deep cuts on the face of the prosecutor, but no weapon had been seen in the hands of the prisoner. He was charged with cutting and stabbing. The surgeon deposed that the wounds appeared to have been inflicted with a knife or razor blade, and not by broken glass. If the wounds had been made by glass, particles of that substance would probably have been found in them; but there were none. The prisoner was acquitted, the infliction of the wounds by a weapon not being considered to have been made out. In another case that occurred in August 1841, the prosecutor was knocked down, and his throat was found severely cut; but there was no proof that a weapon had been used. In the defence it was urged that the wound had been produced by a broken pane of glass; but the surgeon described it as a clean cut, five inches in length, and one inch in depth, laying bare the carotid artery. He considered that it must have been done by a razor or knife; and that it was a cut made by one stroke of the
WOUNDS BY GLASS OR EARTHENWARE.

In the case of Reg. v. Ankers (Warwick Lent Assizes, 1845), a clean cut us from a penknife, about two inches long, and one deep, was proved to have existed on the person of the prosecutor, who had fallen during a quarrel with the prisoner. Some broken crockery was lying near the spot, and it was alleged in the defence that a fall upon this had caused the wound. This allegation was quite inconsistent with the clean and even appearance of the wound, and the prisoner, in whose possession a penknife had been found, was convicted.

In general, wounds made by glass or earthenware are characterised by their great irregularity and the unevenness of their edges. Cases of this kind show that as it is not always possible to know when this sort of defence may be raised, a medical witness should never fail to make a minute examination of a wound which is suspected to have been criminally inflicted. A trial for murder took place at the Worcester Summer Assizes, in 1838, in which it appeared in evidence that the deceased had died from a small punctured wound in the thorax. It was five inches and a half deep, and it had completely traversed the right ventricle of the heart, and led to death by hemorrhage. The wound was supposed to have been produced by a small skewer, which was found near the spot; but in the defence it was alleged that the deceased had fallen over a tub, and that the wound had been caused by a projecting nail. This allegation, however, was negatived by the surgeon, from the fact of its being a clean cut wound. Had it been produced in the manner alleged by the prisoners, the fact would have been indicated by an irregularity of margin. In the case of Bryant (Taunton Lent Assizes, 1849), which involved a charge of maliciously stabbing the prosecutor, the defence was that, as many flints were lying about in the road, and the assault took place in the dark, the wound might have been inflicted accidentally during a fall. The medical witness could not say that the wounds had been positively caused by a weapon; they might have been produced by the flints. The prisoner was acquitted. A careful examination made at the time of the injury would most probably have enabled the witness to give a positive opinion, instead of leaving the case open to doubt. A puncture made by a flint during a fall is not likely to resemble a stab with a knife. The wound would present some marks of laceration and great irregularity. As the wound was under the ear, it was by no means probable from the situation that it could have been thus caused accidentally.

In January 1853, Mr. Hancock, of the Charing Cross Hospital, was enabled, by the careful examination of a wound, to disprove a charge of maliciously wounding made against innocent persons. A little girl was represented to have received, while sitting over an iron grating, a wound in the pudendum, by some persons pushing a toasting-fork, or pointed instrument, between the bars.
of the grating. There were no marks of punctures, which there would have been had this statement been true, but a slight laceration of the parts, such as might have been produced by an accidental fall on the edge of the grating while the girl was in a sitting position. There were also marks of bruises on the thigh, such as would have occurred from an accident of this kind. The mother of the child had made a false charge for the sake of exciting public compassion and procuring money. A proper examination of the injury clearly established that it had resulted from accident. The part of the body in which the injury existed in this case is not usually exposed to lacerations or punctures from accident; but the child, for a certain purpose, had placed herself voluntarily in this position, and had, on her own admission, slipped, and thus probably injured herself.

Lacerated and contused wounds.—Lacerated wounds do not in general present greater difficulty with regard to their origin than those which are incised or punctured. The means which produced the laceration are commonly well indicated by the appearance of the wound. These injuries are generally the result of accident; they are, however, frequently met with on the bodies of new-born children, in which case they may give rise to charges of infanticide. Contused wounds and severe contusions present much greater difficulty to a medical jurist. It is not often in his power to say whether a contused wound has resulted from the use of a weapon, from a blow of the fist, or a fall by reason of the deceased having accidentally fallen against some hard surface. This question is frequently put to medical witnesses, on those trials for manslaughter which arise out of the pugilistic combats of half-drunken men. One of the combatants is generally killed, either by a blow on the head, by a fall, or by both kinds of violence combined. The skull may or may not be fractured; and the person may die of concussion, inflammation of the brain, or from extravasation of blood. The general defence is that the deceased struck his head against some hard substance in falling on the ground; and the surgeon is asked whether the particular appearances might not be explained on the supposition of a fall. This, in general, he admits to be possible, and the prisoner is acquitted. A medical witness is rarely in a position to swear with certainty, that a contused wound of the head must have been produced by a weapon and not by a fall. Some circumstances, however, may occasionally enable him to form an opinion on this point. If there be contused wounds on several parts of the head, with copious effusion of blood beneath the skin, the presumption is that a weapon must have been used. If the marks of violence be on the summit of the head, it is highly probable that they have been caused by a weapon, since this is not commonly a part which can receive injury from a fall. According to the medical evidence given on this question,
WOUNDS FROM FALLS OR WEAPONS. 257

an indictment may or may not be sustained. A case is reported in which a prisoner was indicted for striking the deceased, and fracturing his skull with a piece of brick. The evidence showed that the prisoner struck with his fist, and that the deceased in consequence fell upon a piece of brick, which caused the fracture and led to death. The judges held that this was a fatal variation. (Law Times, Mar. 21, 1846, 501.) Technicalities of this kind will probably be set aside in future cases under the statute 14 and 15 Vict. c. 100; and indeed, in one case (Reg. v. Dodd, Shrewsbury Summer Ass. 1853), Mr. Justice Coleridge is reported to have expressed a strong opinion against the distinction thus made respecting the direct cause of the violence. The prisoner, it was alleged, threw a stone at the deceased, who immediately fell on a stone floor. The deceased was able to go about for several days, but he died, a week after he had sustained the violence, from inflammation of the brain, as a result of fracture of the skull. The medical witness referred the fracture to a blow from a stone. In the defence it was urged that the fracture might just as well have arisen from a fall on the stone floor. Mr. Justice Coleridge is reported to have said that if the prisoner knocked the deceased down, it would make no difference whether the deceased died from a fall on the stone floor or whether a stone was thrown at him.

We may be often in doubt whether in respect to lacerated or contused wounds, a weapon has or has not been used. Contused wounds on bony surfaces, as on the head, sometimes present the appearance of incised wounds, the skin being evenly separated; still when the wound is recent, a careful examination will generally enable a witness to surmount the difficulty. If some time has elapsed before the wound is examined, there will necessarily be great caution required in forming an opinion. In some instances an accurate observation of the form of a wound, and a comparison of it with the supposed weapon, will justify a medical witness in giving a strong opinion on the point. The depth and nature of the wound may be such that no accidental fall would reasonably account for its production. A case of considerable importance in reference to this medico-legal question was tried at the Cornish Assizes, 1851; for a report of which I must refer the reader to the Medical Gazette, xlviii. p. 729. (Reg. v. Teague, Cornwall Summer Assizes, 1851.)

Stabs and cuts.—It has already been remarked, that the law in some cases attaches great importance to the clear proof of the use of a weapon; and a medical man has therefore a serious responsibility thrown upon him when, in the absence of a weapon, he is called upon to say, from an examination of the wound, whether one has or has not been used. The statute on wounding makes no difference in respect to the means by which wounds are inflicted; but the words have been hitherto held by the judges
to imply, in all cases, the use of some weapon or instrument. The following are the provisions of the law: — "Whosoever shall stab, cut, or wound any person, or shall by any means whatsoever, cause to any person, any bodily injury dangerous to life, with intent in any of the cases aforesaid to commit murder, shall be guilty of felony." (1 Vict. c. 85, s. 2.) The word stab has been held to import a wound from a pointed instrument; the word cut, from an instrument having an edge; and the word wound comprises incised, punctured, lacerated, contused, and gunshot wounds; thus including all stabs and cuts, and medically speaking, rendering the separate use of these words in the statute wholly unnecessary. All medical men know that stabs and cuts are varieties of wounds; and it is difficult to understand why these terms should have been retained, and the other varieties of wounding, as "incise, puncture, lacerate, and contusae," omitted. It was formerly held that an indictment for cutting would not be supported if the medical evidence proved that the alleged cut was a stab, and vice versa; and further, in an indictment for cutting and stabbing, it was not considered sufficient to prove that it was a contused or lacerated wound. Again, some doubt existed regarding the meaning of the word weapon. Thus the teeth, the hands or feet uncovered, were held by the majority of the judges not to be weapons; and injuries produced by them, however severe, were not treated as wounds within the meaning of the statute. Parties were tried on charges of biting off fingers and noses, and although the medical evidence proved that great disfigurement and mischief had been done to the prosecutor; yet the degree of injury produced — the division of the cutis — was not so much regarded as the actual method by which it was accomplished. The persons charged were acquitted under an indictment for "wounding." From a trial which took place at the Nottingham Assizes in 1832, it appeared, however, that artificial arms and legs were not exempted under the statute. In the case alluded to, a strenuous effort was made by the prisoner's counsel to show that a wooden arm with which the assault was committed had become, by long use, part of the body of the prisoner, and that, like a natural arm, it ought not to be considered a weapon in law! The objection was overruled.

Within a recent period a great improvement has taken place in this part of our criminal law. The technicalities which arose out of the necessity of strictly defining the nature of a wound, and whether it had or had not been caused by a weapon, are now in great part removed by the 14 and 15 Vict. c. 19, sec. 4. It is herein provided that punishment shall follow the conviction of a person who has inflicted grievous bodily harm, whether with or without any weapon or instrument, or who has maliciously cut, stabbed, or wounded any person. A man has been tried under this statute, for biting off part of the nose of another; and
in another case a man was convicted of maliciously maiming by biting off a large piece of the tongue of the prosecutor. The old objection that the teeth are not weapons, cannot now be raised in defence. The 14 and 15 Vict. c. 100, is also adapted to meet these cases in which trivial technical objections are raised to the description of wounds in an indictment and of the circumstances under which they have been inflicted.

Examination of the dress. — The use of a weapon on these occasions may be sometimes inferred from the dress having been cut; although it is quite possible that a contused wound may be inflicted by a bludgeon through the dress, without tearing or injuring it. The perforation of the dress is by no means necessary for the production of considerable laceration of the skin and muscles, supposing the article of dress to be at all of an elastic or yielding nature. In stabs or cuts with sharp pointed instruments, the part of the dress covering the wound should present marks of having been perforated or cut by the weapon. In self-inflicted or imputed wounds, this is one character by which the correctness of a statement may be tested (See Imputed Wounds). A wound may be indirectly produced by a weapon, and medical witnesses have been often questioned on this point. Thus, the prosecutor may at the time have worn about his person some article of dress which received the blow, and this may have caused the wound. On a trial for maliciously wounding, which took place at the Reading Spring Assizes in 1837, it appeared in evidence, that the prisoner, while poaching, assaulted a gamekeeper by inflicting on his head severe blows with a gun. At the time of the assault, the prosecutor wore a strong felt hat, which, it was contended in the defence, had caused the wounds that formed the subject of the charge. The medical witness admitted that the wounds might have been produced either by the hat or the gun. The prisoner was convicted; but the judge intimated a doubt whether this could be considered a "wounding by a weapon" within the statute. In another case, a blow was struck with a bludgeon at the head of the prosecutor, who wore spectacles. Wounds were produced, which, it was argued in the defence, had resulted from the glass of the spectacles. The prisoner was acquitted. Every case of this kind must be determined according to the circumstances accompanying it. One fact appears to me to be well established from the foregoing statements,—namely, that a medical practitioner should always make a minute and careful examination of wounds which are likely to become the subject of criminal charges. In performing his duties as a surgeon, he is bound, so far as he consistently can, to notice as a medical jurist the characters of all personal injuries.

I am indebted to Mr. Codd, coroner for Essex, for an instructive case, which occurred in August 1853, showing the
importance of comparing the article of dress with the injuries which may have proved fatal. A woman, aged sixty, was found dead in her bed. She had vomited slightly, and there was a small quantity of blood on the floor, which had flowed from the nose. She had been seen in her usual health on the previous night. On inspection, there were found two indentations about the middle of the right parietal bone, and there was a large clot of blood in this situation beneath the skin. On removing this clot, the bone was found fractured to the extent of four inches. Nearly three ounces of dark clotted blood were found on the outer membrane of the brain (dura mater), between it and the skull. All the other viscera were healthy. This was the only injury, and quite sufficient to account for death; but a question arose respecting the mode in which this fracture was caused. It was in evidence that, on the evening before her death, deceased had been suddenly knocked down, while she was walking in a public road, by a man accidentally running against her. One witness stated that she fell heavily on the back of her head, on which at the time she wore a bonnet. She appeared stunned,—was raised up by the men,—some brandy was given to her, and she recovered sufficiently to walk home, after which no one saw her until she was found dead the following morning. Some suspicion arose that the violence done to the head was too great to be accounted for by the fall, and it was a question whether, with such an amount of injury, the deceased could have walked to her home, at the distance of a mile and a half. At first it was thought that this was a case of murder, and a man who lodged in the house with deceased, was suspected. His room was searched, and a hammer with two claws was found. On comparing these claws with the two indentations and fracture, this weapon appeared to account for their production. Deceased and this man had been in the habit of quarrelling, and they were the only persons in the house on this occasion. The lodger said that he let the woman in about 9 o'clock (the fall occurred about 7.30); her appearance presented nothing unusual, and he saw no more of her until called at 7 the next morning, when she was found dead and cold. At the adjourned inquest, the bonnet worn by the deceased at the time of the fall was called for by the coroner. Two indentations were found upon the back part of it corresponding to those on the skull of deceased. The indentations on the bonnet contained dust and dirt, thereby confirming the statements of the witnesses, and rendering it probable that the fall had caused the injury.

The examination of the dress, in this case, cleared up what might have been otherwise doubtful. It is probable that the large internal effusion of blood which caused death did not take place until deceased had reached home, and perhaps as a result of the exertion made. She must have died very soon after she
WOUNDS. HOMICIDE, SUICIDE, OR ACCIDENT. 261

went to bed, as her body was found cold at seven o'clock the next morning. In addition to the caution which this case conveys respecting medical opinions on the origin of wounds, it shows that persons may walk and die at a great distance from the spot where a serious injury to the head has been sustained.

CHAPTER XXIII

WOUNDS INDICATIVE OF HOMICIDE, SUICIDE, OR ACCIDENT—EVIDENCE FROM THE SITUATION OF A WOUND—SUICIDAL WOUNDS IN UNUSUAL SITUATIONS—EVIDENCE FROM NATURE AND EXTENT—SHAPE—EVIDENCE FROM THE DIRECTION OF A WOUND—WOUNDS INFLECTED BY THE RIGHT OR LEFT HAND—ACCIDENTAL AND HOMICIDAL STABS—EVIDENCE FROM THE PRESENCE OF SEVERAL WOUNDS—THE USE OF SEVERAL WEAPONS—TWO OR MORE MORTAL WOUNDS—WOUNDS PRODUCED SIMULTANEOUSLY OR AT DIFFERENT TIMES.

Wounds indicative of homicide, suicide, or accident.—Supposing that the wound which is found on a dead body is proved to have been caused before death, it will next be proper to inquire whether it was the result of suicide, homicide, or accident. It might at first sight be considered that the determination of a question of this nature was wholly out of the province of a medical jurist. In some instances it may be so, and the settlement of it is then properly left to the legal authorities; but, in a large number of cases, it is so closely dependent for its elucidation on medical facts and opinions, that juries could never arrive at a satisfactory decision without medical evidence. Let us suppose, then, that a medical jurist is consulted in a doubtful case, —What are the points to which he must direct his attention? These are, with regard to the wound, its situation, its nature and extent, and its direction.

Evidence from the situation of a wound.—It is a general principle in which most medical jurists agree, that wounds, inflicted by a suicide, are usually confined to the anterior or lateral parts of the body. The throat and chest are commonly selected, where cutting instruments are employed; while the chest, especially in the region of the heart, the mouth, the orbit and the temples, are the spots generally chosen for the perpetration of suicide by fire-arms. But it is obvious, that any of these parts may be also selected by a murderer, with the especial design of simulating a suicidal attempt; therefore the mere situation of a wound does not suffice to establish the fact of suicide. Dr. Smith considers, in reference to pistol-wounds, that if the weapon has been introduced into the deceased's mouth, and there dis-
charged, we may almost take it for granted that "it has not been done by another" (For. Med. p. 302); but this inference has been rather too hastily drawn, because it is quite within the range of possibility, that a cool and calculating assassin may purposely resort to this method of destroying his victim, in order to conceal his crime. In suicidal wounds from fire-arms, a discolouration by powder of the fingers of the hand which discharged the weapon is sometimes observed; this has also been looked upon as a source of evidence of suicide under doubtful circumstances, but a similar objection, although not with equal force, might be made to its admission. Some have regarded it as fully established in legal medicine, that when wounds exist at the posterior part of the body, it is a positive proof that they have not been self-inflicted. This situation is certainly very unusual in cases of suicide; but, as Orfila observes, it is not the situation, so much as the direction of a wound, which here furnishes evidence against the presumption of suicide. A wound, traversing the body from behind to before in a direct line, is not very likely to have resulted from a suicidal attempt; at least it must be obvious that it would require more preparation and contrivance on the part of a self-murderer, so to arrange matters, that such a wound should be produced, than we can believe him to possess at the moment of attempting his life. Besides, his object is to destroy himself as quickly and as surely as circumstances will permit; he is, therefore, not likely to adopt complicated and uncertain means for carrying this design into execution. Nevertheless, we must not always expect to find suicidal wounds in what a surgeon would pronounce to be, the most appropriate situation to produce instant destruction. A want of knowledge, or a want of resolution on the part of a suicide, or the accidental slipping of the hand, will often cause a wound in a part where we might least expect to find it.

Wounds which result from accident or suicide are generally in exposed parts of the body. An incised wound in a concealed or not easily accessible part is presumptive of murder; because this kind of injury could have resulted only from the deliberate use of a weapon. Suicidal wounds are, however, sometimes found in the most unusual situations. In December, 1842, a surgeon destroyed himself by cutting through the brachial artery and the principal veins of his left arm with a penknife: and in another instance, which occurred in 1839, a young man committed suicide by dividing the arteries of the fore-arm on both sides. It is very rare that we find suicidal stabs in the abdomen or throat, but an instance occurred a few years since, in which a woman destroyed herself by a stab in the lower part of the abdomen; and several similar cases are recorded by medico-legal writers. In an attempt at suicide, which fell under my own observation, a stab was inflicted by a carving knife on the fore-part of the neck,
traversing the parts from the windpipe to the spinal column. In regard to situation, it has been remarked, that there is no wound which a suicide is capable of inflicting upon himself, which may not be produced by a murderer; but there are many wounds inflicted by a murderer, which from their situation and other circumstances, a suicide would be incapable of producing on his own person. We cannot always obtain certainty in a question of this kind: the facts will often allow us to speak only with different degrees of probability. [A remarkable instance of the singular situation selected for suicidal wounds is reported in the Medical Gazette, Vol. xlv. p. 439.]

The situation of a wound sometimes serves to show whether it be of an accidental nature or not,—a point often insisted on in the defence. Accidental wounds generally exist on those parts of the body which are exposed. Some wounds, however, forbid the supposition of accident even when exposed; as deeply incised wounds of the throat, and gunshot wounds of the mouth and temples. (For the report of a case in which an accidental wound on the head, by an axe, closely simulated a homicidal wound, see Casper's Wochenschrift, May 24, 1845.)

Evidence from the nature and extent of a wound.—Generally speaking, the wound met with on the body of a suicide, when fire-arms have not been used, is incised or punctured. Contused wounds are rarely seen in cases of suicide, because in producing them there is not that certainty of speedily destroying life to which a self-murderer commonly looks. There are, of course, exceptions to this remark; as where, for instance, a man precipitates himself from any considerable height, and is wounded by the fall. Circumstantial evidence will, however, rarely fail to clear up a case of this description. Greater difficulty may exist when life is destroyed by a contused wound, voluntarily inflicted. A case is related by a medico-legal writer in which a man first attempted to destroy himself by running with his head against a wall; and not having succeeded in this attempt, he struck himself repeatedly on the forehead with a cleaver. By this he produced such violent injury to the brain, that death soon followed. The man was seen to commit the crime by several witnesses; had this not been the case, the nature of the wound was such as to excite suspicion that it had been inflicted by another, and that the man had been murdered.

A close attention to the shape of wounds made by cutting instruments, will sometimes lead to the development of cases rendered doubtful from the circumstances under which the dead body of a wounded person is found. A few years since, the body of a farmer was found lying on a high road, in one of the midland counties. The throat was severely cut, and he had evidently died from the bleeding which had taken place. A bloody knife was discovered at some distance from the body, and
this, together with the circumstance of the pockets of the deceased having been rifled, led to a suspicion of murder. The suspicion was confirmed when the wound in the throat was examined by a surgeon. It was cut, not, as is usual in suicides, by carrying the cutting instrument from before backwards, but as the throats of sheep are cut, when slaughtered by a butcher. The knife had been passed in deeply under and below the ear, and had been brought out by a semicircular sweep in front, all the great vessels of the neck, with the gullet and wind-pipe, having been divided from behind forwards. The nature of this wound rendered it at once improbable that it could have been self-inflicted; and it further served to detect the murderer, who was soon afterwards discovered. The prisoner, who was proved to have been a butcher, was subsequently tried and executed for the crime.

It is necessary to bear in mind, that maniacs, when they commit suicide, often inflict upon themselves wounds of a very extraordinary nature,—such as would, at first view, lead to a suspicion that they had been produced by the hand of a murderer: and, therefore, the rules which are here laid down to distinguish homicidal from suicidal wounds, must be very guardedly applied to the cases of those individuals who are known to have laboured under insanity. Perhaps one of the most remarkable cases of this kind is that recorded by Mr. Tarleton. A gentleman was found lying in a state of insensibility in the kitchen of his house, with a cleaver by his side. On examining the head, upwards of thirty wounds were found over the posterior portion of the occipital bone. The wounds, many of which were superficial, had a horizontal direction from behind forwards. One, however, had removed a portion of the skull from the middle of the lambdoidal suture, so that the brain had escaped. This person, who was a lunatic, died four days afterwards, but recovered so far as to admit that he had produced the wounds on himself, of which, from other circumstances, there could have been no doubt. This was a most unusual way of committing suicide. Had the deceased been found dead on a public highway, thus wounded, it is probable that a strong suspicion of murder would have arisen. In 1850, a case occurred at Guy’s Hospital, in which a person in a fit of delirium tore away the whole of the abdominal muscles from the lower and fore-part of the abdomen. Had the body of this individual been found dead with such an unusual and serious personal injury, it is not improbable that it would have been pronounced homicidal and not suicidal. In this point of view, a case which occurred to Dr. W. Burke Ryan is also of interest. The suicide here contrived to cut his throat exactly between the os hyoides and the larynx, having previously made two distinct cuts on the thyroid cartilage. The wound was of an extensive kind, reaching backwards through the pharynx to the cervical
SUICIDAL WOUNDS OF THE THROAT.

vertebrae, one of which had been touched by the razor. The carotids and jugulars had escaped, but some of the larger branches were divided. The man survived about seven hours. (Med. Times, Jan. 17, 1852, page 73. For another case of extensive wounds in the throat by a lunatic, see Med. Times and Gazette, August 27, 1853, p. 219.) Cases of this kind should be borne in mind, when we are called upon to speak to the possibility or impossibility of certain wounds found on a dead body, having been self-inflicted. (Med. Gaz. xxiv. 276.)

The extent of a wound, by which we are to understand the number and importance of the parts injured, must in these cases be always taken into consideration. It has been somewhat hastily laid down as a rule, that an extensive wound of the throat, involving all the vessels and soft parts of the neck to the vertebral column, could not be inflicted by a suicide. Although, in general, suicidal wounds of this part of the body do not reach far back, or involve the vessels of more than one side, yet we find occasionally in suicide that all the soft parts are completely divided to the vertebrae. These are cases in which, perhaps, with a firm hand, there is a most determined purpose of self-destruction. In a case of suicide, observed by Marc, the weapon had divided all the muscles of the neck, the larynx, and gullet,—had opened the jugular veins and both carotid arteries,—and had even grazed the anterior vertebral ligament. A wound so extensive as this, is certainly rarely seen in cases of suicide; but there is no ground for the assertion, that these extensive wounds in the throat are incompatible with self-destruction.

Incised wounds in the throat are generally set down as presumptive of suicide; but murderers sometimes wound this part for the more effectual concealment of a crime. Circumstances connected with the form and direction of the wound, often, in such cases, lead to detection; for, unless the person attacked be asleep or intoxicated, resistance is offered,—evidence of which may be obtained by the presence of great irregularity in the wound, or the marks of other wounds on the deceased. In some instances, however, it is extremely difficult to say whether the wound be homicidal or suicidal,—the medical facts being equally explicable on either hypothesis. (See case by Marc, Ann. d’Hyg., 1830, ii. 408; another by Devergie, ib. 414; and a third by M. Ollivier, Ann. d’Hyg., 1836, i. 394.)

The nature or the extent of a wound or of other injuries on the person, will sometimes allow us to distinguish, very positively, accident from homicide. These personal injuries may be such, that they could not possibly have had a suicidal or accidental origin. In a case that occurred at Manchester, in October 1836, it was shown by the medical evidence, that seven ribs were fractured on one side of the chest of the deceased, and five on the other. The person charged with murder alleged in defence,
that he had merely struck the deceased a slight blow, and that the ribs were broken subsequently by an accidental fall. The medical witness, however, satisfied the Court that the fall, as described by the prisoner, was inadequate to the production of such extensive violence; and that even had the deceased fallen on one side, this would not account for the fracture of the ribs on the other. When, therefore, we find in a dead body, severe injuries referred to a fall, we should search the whole of the body carefully for marks of violence. The insides of the arms or thighs might present marks of injury, which could not possibly be explained on the supposition of an accidental fall. Severe contusions on both sides of the body, or anteriorly and posteriorly, commonly indicate homicidal violence.

Evidence from the direction of a wound. — The direction of a wound has been considered by some to afford presumptive evidence sufficiently strong to guide a medical jurist in his inquiry. It has been remarked that in most suicidal wounds which affect the throat, the direction of the cut is commonly from left to right, either transversely or passing obliquely from above downwards: in suicidal stabs and punctured wounds, the direction is commonly from right to left, and from above downwards. In left-handed persons, the direction would, of course, be precisely the reverse. Suicidal wounds are, however, subject to such variation in extent and direction, that it is scarcely possible to generalise with respect to them. Nevertheless, an attention to these points may sometimes be of real assistance to the inquirer, especially when the body has not been moved from its position. It is recommended that the instrument with which the wound has been inflicted should be placed in either hand of the deceased, and the extremity moved towards the wounded part, so that it may be clearly seen whether the direction of the wound could or could not correspond to it in any position. It might happen that neither arm would reach the wounded part, so as to inflict a wound of the particular direction observed: this may be the case in wounds situated on the back. It is obvious that if a murderer makes an incised wound in the throat from behind, the direction will be the same as that commonly observed in cases of suicide. (See on this point the case of Reg. v. Dalamas, Cent. Crim. Court, May 1844.) Again, if the person attacked be powerless the wound may be deliberately made, so as to simulate a suicidal act; indeed murderers would seldom attack the throat, but with the design of simulating an act of suicide. A homicidal stab may also take the same direction as one which is suicidal; but this would be confined to those cases in which the murderer was placed behind or aside. If in the front of the person whom he attacks, the direction would probably be from left to right; but in suicides, where the right hand is commonly used, it is the reverse. All oblique wounds, passing from above down-
Wounds inflicted by the right or left hand.

Wounds, are common to homicide and suicide; but those which take an oblique course from below upwards are generally indicative of homicide; it is at least extremely rare, that a suicide, unless a lunatic, thus uses a weapon. Homicidal incisions, especially in the throat, are often prolonged below and behind the skin forming the angles of a wound, deeply into the soft parts. Those which are suicidal rarely possess this character; they terminate gradually in a sharp angle, and the skin itself is the furthest point wounded,—the weapon is not carried either behind, below, or beneath it. Exceptions to these characters may exist; but in a dark and intricate subject of this nature, we have only these limited rules to guide us. The instrument with which a wound is supposed to have been inflicted should be adapted to the edges of the incision: its sharpness may be compared with the cleanliness and evenness of the cut, and its length with the depth of the incision or stab. It is no uncommon occurrence for a murderer to substitute some instrument, belonging to the deceased or another person, for that which he has employed; and this by its size, shape, or bluntness, or other peculiarities, will not account for the appearances presented by the wound.

Wounds inflicted by the right or left hand.—Some remarks have been made about the direction of a cut or a stab, varying according to whether the right or the left hand has been used by a suicide. It is important for a medical jurist to be aware, that there are many persons who are ambidextrous, i.e. who have equal facility in the use of the right or the left hand. This may not be generally known to the friends of the deceased: and such persons are often pronounced, even by those who have associated with them, to have been right-handed. A want of attention to this point is said to have been one of the circumstances which led to a suspicion of murder in the case of Sellis. (Wills' Circ. Evidence, 97.) He was found dead on his bed with the throat cut,—the razor was discovered on the left side of the bed; whereas it was generally supposed and asserted that he was a right-handed man. The truth was, he was ambidextrous,—equally expert in the use of the razor with his left and right hand; and thus the apparently suspicious circumstance of the razor being found on his left side, was at once explained away.

Accidental stabs.—Severe incisions on vital parts do not often happen by accident; but severe punctures and stabs affecting vital organs have frequently an accidental origin. These stabs arise generally from falls, while the individual is in the act of running with a pointed instrument in his hand or his pocket. There is one character which, when thus produced, they are commonly observed to possess, namely, that their direction is from below upwards. In this way the truth of a defence may
be sometimes tested, as when a prisoner alleges that the deceased threw himself or fell upon the weapon. Homicidal stabs may be likewise directed from below upwards; but this is somewhat rare, and not probable, unless an individual be stabbed by an oblique blow, while in the recumbent posture. Rules of this kind may appear to be susceptible of but little practical application; yet cases occasionally present themselves, wherein a close attention to the situation and direction of wounds may materially assist the medical jurist in forming an opinion. In a case of alleged murder, which was tried in 1843 at the Central Criminal Court, the surgeon deposed, that he found on examining the body of the deceased, a stab on the left side of the chest, near the armpit, about six inches in depth. It had wounded the right lung, and had penetrated obliquely into the right auricle of the heart, passing from left to right. He contended, very properly, that, considering the situation and direction of the wound, it was very improbable that the deceased could have inflicted it upon himself. The fact that there may be some instances in which rules of this kind will not be applicable, must not deter us from endeavouring to make a cautious application of them in doubtful cases.

At the trial of a Mrs. Mackinnon for murder (1823), a careful observation of the direction of a stab in the chest clearly proved the falsehood of the defence. The deceased had been stabbed with a knife, and on an inspection of the body it was found that the wound, which was situated over the cartilage of the second left rib, penetrated towards the left, backwards, and very much downwards, into the lungs. On the part of the prosecution it was alleged that the prisoner held a long table-knife daggerwise, drew a blow from her left ear, and struck the deceased in a direction downwards, forwards, and to her right side. The prisoner alleged in defence that she merely held the knife before her, sloping upwards, to deter the deceased from attacking her; that he stumbled forward, and fell upon the point of the knife. This statement was in some measure confirmed by some bystanders. As the witnesses on both sides were intoxicated and of disreputable character, the important medical fact to guide the jury was the direction of the wound. This was wholly inconsistent with the statement of the prisoner, but perfectly in accordance with the evidence for the prosecution. (Ed. Monthly Journal, Nov. 1851, page 418.)

Evidence from the presence of several wounds.—In suicides, commonly, one wound only is seen, namely that which has destroyed life; and the presence of several wounds on the body, or the marks of several attempts around the principal wound, have been considered to furnish presumptive evidence of murder. But it need hardly be observed that any inferences of this kind must be very cautiously drawn, since not only may a murderer destroy his
EVIDENCE FROM SEVERAL WOUNDS.

269

victim by one wound, but a suicide may inflict many, or leave the marks of several attempts, before he succeeds in his purpose. A case is reported in which a gentleman, labouring under mania, attempted to destroy himself. Besides many wounds on the fore-arm, neck, and face, which disfigured him, there were twenty-two in front of his chest. One of these had traversed the heart, producing death after some hours, by causing extravasation of blood. (Lancet, July 1839.) In wounds of the throat, owing to ignorance of the situation of vital parts, or to tremulousness of the hand, a suicide often produces one or more incisions of greater or less extent near that which may have destroyed him. This is especially the case when the instrument happens to lodge in the first instance on the cartilages of the larynx. The same remark applies to suicidal stabbs, when the point of the weapon, in being directed against the chest, comes in the first instance in contact with the ribs or their cartilages. With respect to the throat, many cases might be cited in which, two, three, and even six or more incisions, have been made in this part by suicides before they have destroyed themselves. A case is related by Dr. Handyside (Ed. Med. and Surg. Jour. Jan. 1838), in which a gentleman who had studied medicine destroyed himself by inflicting several wounds on his throat. Incisions were found on each side, just below the angle of the jaw and in the hollow behind it. They were irregular in form, and bore the character of deep stabs. The only important vessel divided was the internal jugular vein on the right side; but, nevertheless, a large quantity of blood was lost, and this, no doubt, as it is stated by Dr. Cormack, was the real cause of death. The case is in many points of view singular; for such wounds, so far as I know, have never before been found in cases of suicide. It would appear that the deceased was ambidextrous, and that the wounds on each side of the neck were inflicted by the hand of the opposite side. The following case, which occurred in London in 1839, is somewhat similar:—A lady who had been for several days in a desponding state was found one morning dead in her bed in a sitting posture. On examination, two very deep and extensive wounds, which had divided the principal blood-vessels, were perceived on the right side of the neck. There were two penknives on the bed covered with blood. From the situation and other characters of the wounds, it was inferred that they must have been inflicted with the left hand: although nothing satisfactory could be ascertained on this point. The husband and son had slept in the adjoining room. There was no doubt that this was a case of suicide; although it is singular that two deep wounds should have been found thus inflicted by two different weapons on the right side of the neck, in the case of a person who was not known to be left-handed.

The use of several weapons.—In general, suicides, when foiled
in a first attempt, continue to use the same weapon; but sometimes, after having made a severe incision in the throat, they will shoot themselves, or adopt other methods of self-destruction. These cases can only appear complicated to those who are unacquainted with the facts relative to self-murder. Neither the presence of several wounds by the same kind of weapon, nor of different wounds by different weapons, can be considered, of themselves, to furnish any proof of the act being homicidal. One instance has been already related, in which a lunatic, in committing suicide, inflicted thirty wounds upon his head. In a case of murder, when many wounds are found on a dead body, it may happen that the situation or direction of some will be incompatible with the idea of a suicidal origin. Thus a stab or cut may be close to a contusion or contused wound, and although a fall or other accident might account for the latter, the former would indicate violence previously inflicted.

Two or more mortal wounds.—When we find several wounds on the body of a suicide, it generally happens that one only bears about it a mortal character; namely, that which has caused death. On this account it has been asserted by some medical jurisprudents, that when two mortal wounds are found upon a body, and particularly if one of them be of a stunning or stupefying tendency (i.e., affecting the head), they must be considered incompatible with suicide. An inference of this kind can be applied to those cases only in which the two wounds, existing on different parts of the body, were likely to prove immediately fatal. It must, however, be borne in mind that all suicides do not immediately perish from wounds which are commonly termed mortal; on the contrary, they have often the power to perform acts of volition and locomotion, which might by some be deemed wholly incompatible with their condition. It is very difficult to say whether one wound was likely to destroy life so rapidly as to render it impossible for an individual to have inflicted another upon himself; but when there are several distinct incisions on the throat, each involving important blood-vessels, there is good reason to infer that they have resulted from an act of murder. There are no rules by which, in unknown cases, the instantaneous mortality of wounds can be accurately determined,—a fact which will be apparent hereafter, from a description of wounds of the head, heart, and throat.

It is not possible to say, from the mere discovery of marks of contusion or injury on the head, that the deceased must have necessarily laboured under insensibility or concussion, and have therefore been afterwards unable to inflict any other wound upon himself. Injuries of the head are attended with the most singular anomalies in this respect. One individual will be rendered insensible and powerless by a blow which may leave scarcely any appreciable marks, while another will be able to walk and exert
himself when the skull has been fractured and depressed, blood effused, and even when a portion of brain has been lost: in short, the appearances may be such as to induce many surgeons to express an opinion that death must have taken place instantaneously. (See case, ante, p. 264.) It is quite right that a medical jurist should be fully prepared for the occurrence of such anomalies cases; but a strong suspicion of homicide may fairly exist, when, besides marks of great injury to the head, a severe cut or stab is found on the body. A man is not likely to cut or stab himself after having sustained very severe violence to the head; but it is quite possible that he may have had the power of precipitating himself from an elevated spot, and thereby of producing great injury to the head, after having previously attempted to cut his throat or to stab himself.

Wounds produced simultaneously or at different times.—When several wounds are found on a dead body, the question is frequently asked,—Which was first received? If one be what is commonly called mortal, and the others not, it is probable that the latter were first inflicted. This remark applies both to cases of homicide and suicide; but it is apparent that when, in a murderous assault, a person has been attacked by several individuals at once, the wounds may have been simultaneously produced. This is, however, a question to which it is not easy to give a general answer. Each case must be decided from the special circumstances attending it; and in most instances, unless some direct evidence be afforded, a medical opinion can be little more than conjectural. I here refer to it, because it is a question almost always put in a Court of law; and a witness should at least prepare himself to meet it, by a proper examination of the medical circumstances of the case.

The case of Reg. v. Spicer (Berks Lent Assizes, 1846) affords an illustration of the importance of examining wounds minutely as well as the locality where a dead body is found. The prisoner was charged with the murder of his wife, and the evidence against him was chiefly circumstantial. The deceased was found dead at the foot of a stair, as if she had accidentally fallen. The parietal bone was fractured, and the fracture had extended to the base of the skull. The brain was lacerated and there was great effusion of blood. The second vertebra of the neck was fractured, and the spinal marrow torn through. These injuries were quite sufficient to account for death; and had they existed alone, there might have been no reason to charge the husband with the murder. But there was a wound on each temple, partly lacerated and partly bruised, and a branch of the right temporal artery had been divided; the injury having been inflicted, apparently, with a pointed blunt instrument. There were marks of blood on the wall at the top of the staircase, and a pointed stone, covered with blood, was found near the body.
It was therefore obvious, as the deceased had fallen on the summit of the head, that the injuries to the two temples laterally, could not have accidentally produced, for there was no projecting body against which she could have fallen in her descent; and when the force of the fall had been spent on the head, her body could not have rolled over, so as to produce mixed punctures and lacerated wounds on both temples. All the facts tended to show that a murderous assault had been made upon her at the top of the stair, and that she had afterwards fallen or had been pitched headlong backwards. The injuries received previous to the fall might have stunned her, and might not have sufficed to account for death; but their nature and situation furnished strong proof that they could not have arisen from any cause operating simultaneously, and that they were neither of accidental nor suicidal origin. The prisoner was convicted and executed. (Med. Gaz. xxxvii. 610.)

If several wounds have been inflicted through the dress, an examination of this may sometimes suffice to show which was first received. A man, in struggling with an assailant, received three stabs with a knife—two on the left elbow, and the third in the back. The latter was at about the level of the eighth rib; it was vertical to the chest, and had clean edges. The lower margin was obtuse—the upper acute; hence it was evident that the cutting edge of the weapon had been directed upwards. It had traversed the left lung and the heart, and had caused immediate death. It was obvious, on examination, that this mortal wound had been first received, and the stabs at the elbow inflicted subsequently. These two stabs, which were slight, had divided the cloth coat and shirt, and had only grazed the skin, so that no blood had been effused. But the edges of the cuts in the cloth coat and shirt were stained with blood; hence it was evident that they must have been produced by a weapon already rendered bloody by a previous wound. The fact was of some importance in the case, and the correctness of the medical opinion was confirmed by the evidence at the judicial inquiry. (See Ann. d’Hygiène, 1847, i. p. 461.)
CHAPTER XXIV.

Evidence from circumstances.—In pursuing the examination of the question respecting the homicidal or suicidal origin of wounds, the attention of the reader may be called to the force of evidence which is sometimes derived from the circumstances under which the body of a person, dead from wounds, is discovered. It may be said that this is a subject wholly foreign to the duties of a medical jurist; but I cannot agree to this statement: there are very few in the profession, who, when summoned to aid justice, by their science, in the detection of crime, do not seek for circumstances by which to support the medical evidence required of them. A practitioner would certainly be wrong to base his professional opinion exclusively on circumstantial proofs: but it is scarcely possible for him to avoid drawing an inference from these, as they fall under his observation. His evidence may be of itself weak, and insufficient to support the charge against an accused party; in such a case, if any suspicious circumstances have come to his knowledge, he may be often unconsciously induced to attach greater importance to the medical facts than he is justified in doing: in short, he may, through a feeling of prejudice, which it is not always easy to avoid, give an undue force to the medical evidence. But if a proper degree of caution be used in drawing inferences from the circumstantial proofs, and they are not allowed to create a prejudice in his mind against the accused, a practitioner is, I think, bound to observe and record them; for being commonly the first person called to the deceased, many facts, capable of throwing an important light on the case would remain unnoticed or unknown, but for his attention to them. The position of a dead body,—the distance at which a knife or pistol is found,—the direction of the instrument,—whether situated to the right or left of the deceased,—the marks of blood or wounds about the person or of blood on the clothes, or furniture of the apartment, are circumstances
which must assist materially in developing the real nature of a case, and in giving force to a medical opinion. Many of these circumstances can fall under the notice of him only who is first called to the deceased; and, indeed, if observed by another, no advantage could be taken of them without the assistance of a medical man.

In the case of Davidson, who was tried for murder before the Aberdeen Spring Court of Justiciary, April 1855, the origin of certain wounds on the head of the deceased turned on the question of the presence or absence of nails at the head of the bed. On this occasion Lord Deas, the judge, remarked:—"A medical man when he sees a dead body should notice every thing." There was reason to believe that some nails had been driven into the head of the bed subsequently to the infliction of the violence, so as to give the appearance of the wounds having resulted from accident. There was some medical evidence in support of the view of their accidental origin, but according to Dr. Ogston, there was no blood on the bedstock where the nails were represented to have been: and as the woman had died from haemorrhage, this was not likely to have escaped being stained with blood. In his opinion, too, the nails would not have accounted for the wounds on the temple as the result of accident. The whole of the difficulty in this case appears to have arisen from want of proof that there were no nails in the bedstock when the woman was found dead. The prisoner was discharged on a verdict of "not proven."

Among the questions which present themselves on these occasions are the following:—Is the position of a wounded body that which a suicide could have assumed? Is the distance of a weapon from the body such as to render it improbable that it could have been placed there by the deceased? In answering either of these questions, it is necessary to take into consideration the extent of the wound, and the period at which it probably proved fatal. Again, it may be inquired: Has the deceased bled in more places than one? Are the streams of blood all connected? Are there any marks of blood on his person or clothes, which he could not well have produced himself? Are there any projecting nails or other articles which might account for wounds on the body as the result of accident? These are questions, the answers to which may materially affect the case of an accused party; and a practitioner, in noticing and recording the circumstances involved in them, ought therefore to exercise due caution and deliberation. "The consideration of the nature of circumstantial evidence," observes Starkie, "and of the principles on which it is founded, merits the most profound attention. It is essential to the well-being at least, if not to the very existence of civil society, that it should be understood, that the secrecy with which crimes are committed
WOUNDS. MEDICAL CIRCUMSTANCES.

will not insure impunity to the offender. At the same time it is to be emphatically remarked, that, in no case, and upon no principle, can the policy of preventing crime and protecting society, warrant any inference which is not founded on the most full and certain conviction of the truth of the fact, independently of the nature of the offence and of all extrinsic considerations whatever. Circumstantial evidence is allowed to prevail to the conviction of an offender, not because it is necessary and politic that it should be resorted to, but because it is in its own nature capable of producing the highest moral degree of certainty in its application. Fortunately for the interests of society, crimes, especially those of great enormity and violence, can rarely be committed, without affording vestiges by which the offender may be traced and ascertained. The very measures which he adopts for his security, not unfrequently turn out to be the most cogent arguments of guilt. On the other hand, it is to be recollected, that this is a species of evidence which requires the utmost degree of caution and vigilance in its application: and, in acting upon it, the just and humane rule, impressed by Lord Hale, cannot be too often repeated:—tutus semper est errare in acquietando quam in puniendo, ex parte misericordiae quam ex parte justitiae.” (Vol. i. p. 480.) Evidence is direct when a fact is proved by witnesses, and circumstantial when the fact is at once proved by circumstances. More commonly the evidence is presumptive, i.e. founded on an inference from circumstances.

The common rule respecting the admissibility of this kind of evidence applies to circumstances of a medical as well as those which are of a physical or moral kind. Medical circumstances, when properly observed, are often of the highest importance. In order to convict an accused person on circumstantial evidence, the facts proved in the case should square with the hypothesis of his guilt, and be utterly inconsistent with his innocence; or, in the language of another learned judge, a certain number of facts should be incontestably proved in the case, which are quite inconsistent with the innocence of the prisoner. These facts should be such as to render it impossible, in the minds of a jury, that any one but the prisoner could have committed the murder.

There are many cases on record in which an observance of slight and unexpected circumstances by medical men has led to the detection of offenders. In the Life of Sir Astley Cooper, it is mentioned, that when called to see Mr. Blight, of Deptford, who had been mortally wounded by a pistol-shot in the year 1806, he inferred from an examination of the localities, that the shot must have been fired by a left-handed man. The only left-handed man near the premises at the time was a Mr. Patch, a particular friend of the deceased’s, who was not in the least suspected. This man was, however, subsequently tried and convicted of
the crime: — and he made a full confession of his guilt before execution.

The rules for investigating a case of poisoning (see ante, p. 29) may be equally observed in many cases of death from violence. Among the circumstances to which a medical witness should specially direct his attention on these occasions are the following: —

1. **The position of the body.** — The body may be found in a position which the deceased could not have assumed on the supposition of the wound or injury having been accidental or suicidal. The position of a dead wounded body is often only compatible with homicidal interference, either at the time of death, or immediately afterwards. In order to determine the probable time of death, we should always notice whether there be any warmth about the body,—whether it be rigid, or in a state of decomposition, and to what degree this may have advanced. In the case of a female who was found dead in her apartment with her throat cut, in November 1847, it was ascertained that when first discovered, the body was so warm as to render it highly probable that the crime must have been committed within an hour. This observation tended to prove the innocence of a party who was suspected of the murder, because it was known that he had been absent from the house for at least five hours.

2. **The position of the weapon.** — If a person has died from an accidental or self-inflicted wound, likely to cause death either immediately or within a few minutes, the weapon is commonly found either near to the body or within a short distance of it. If found near, it is proper to notice on which side of the body it is lying; if at a short distance, we must consider whether it might not have fallen to the spot, or been thrown or placed there by the deceased. If there has been any interference with the body, all evidence from the relative position of it and the weapon will be inadmissible. In a case which was referred to me some years since, a woman had evidently died from a severe incision on the throat, which was homicidally inflicted; the weapon, a razor, was found under the left shoulder, a most unusual situation, but which, it appears, it had taken owing to the body having been turned over before it was seen by the surgeon who was first called. We must remember that it is quite compatible with suicide that a weapon may be found at some distance, or in a concealed situation; but it is much more frequently either grasped in the hand, or lying by the side of the deceased.

In one instance, it is stated the deceased was discovered in bed with his throat cut, and the razor lying closed or shut by his side. In another case, the bloody razor closed, was found in the deceased's pocket. In the case of a Captain Wright, who was found dead in one of the French prisons (during the war with
CIRCUMSTANCES INDICATIVE OF HOMICIDE.

France), it is stated on good authority that the razor shut, was held in the hand of the deceased. In a wound involving the great blood-vessels of the neck, it is most improbable that there should be any power to close or shut the razor with which the wound was inflicted; and there are fair grounds to suspect interference when a razor is thus found closed. There is, however, one circumstance in relation to a weapon strongly confirmatory of suicide. If the instrument be found firmly grasped in the hand of the deceased, no better circumstantial evidence of suicide can, perhaps, be offered. It is so common to find knives, razors, and pistols grasped in the hands of suicides, that it is quite unnecessary to produce cases illustrative of this statement. The grasping of a weapon appears to be owing to muscular spasm persisting after death and manifesting itself under the form of what has been called cadaveric spasm — a condition quite distinct from rigidity, although often running into it. It does not seem possible that any murderer could imitate this state, since the relaxed hand of a dead person cannot be made to grasp or retain a weapon, like the hand which has firmly held it by powerful muscular contraction at the last moment of life. Of this the case of Reg. v. Suville, Nottingham Summer Assizes, 1844, furnishes an illustration. A woman was found dead with her throat cut, and there was a razor loose in her hand. There was no blood upon the hand which held the razor, and this, together with the fact of its being quite loose, rendered it certain that it must have been placed there by the prisoner after having cut his wife's throat. A case, in which the facts were somewhat similar, was tried at the Liverpool Winter Assizes, 1853 (Reg. v. Heywood). The deceased in this case, a female, was found dead in bed with her throat cut. The medical evidence showed that the wound was six inches from right to left, — extending across the throat to a point under the left ear, the upper portion of the windpipe was severed, and the jugular vein, as well as the muscular branches of the carotid artery, were divided. The medical witnesses considered that the wound in the throat had not been inflicted by herself. It was such a wound as a left-handed person would have inflicted, and the hand inflicting it, as well as the weapon, could not have escaped being marked with blood. It appears, that when the body was found there was a razor in the right hand, not tightly held. The arms were folded across the chest, the right hand resting on the left, the back of the razor being towards the person of deceased. There was no blood on the hands, arms, or chest, and only one small spot on the razor. There was blood on the under side of a pillow, and a corresponding stain on the bolster, showing that this must have been turned over, and the head placed on the clean side after the infliction of the wound. All the circumstances concurred in showing that an attempt had been made to simulate an act of
suicide, while the facts were only consistent with homicide. The prisoner was connected with the act by the moral as well as circumstantial evidence, and he was convicted and executed.

The deceased may be found with some article grasped in the hand. (See case, Ann. d’Hyg. 1829, i. 464.) It may be her own or the prisoner’s hair torn off in the struggle for life; and on this point a question of identity may be easily raised. (Reg. v. Ellison, Bodmin Summer Assizes, 1845.) In a case which occurred to Dr. Marc, a woman was found assassinated in her house, and when the body was discovered, a small snuff-box was still held firmly in one hand. This proved that the murder must have taken place very suddenly, and without any resistance on the part of the deceased. (Ann. d’Hyg. 1829, i. 465.)

If the weapon cannot be discovered, or if it be found concealed in a distant place, this is strongly presumptive of homicide, provided the wound be of such a nature as to prove speedily fatal. In the case of Lord William Russell (1840) no weapon could be discovered; and although the wound in the throat bore some of the characters of a suicidal incision, this fact alone was sufficient to show that it must have been the act of a murderer. With respect to the weapon being found at a distance from the body, other circumstances should be taken into consideration before any opinion is expressed. We may observe whether the weapon, if it be a sharp cutting instrument like a razor, has been recently notched; for this might show that a degree of force or violence has been used, not easily reconcilable with the suicidal use of the instrument. The well-known case of the Earl of Essex, who was found dead in the Tower, in July 1683, gave rise to a doubt on this point. The deceased was discovered with his throat cut, and a razor without a handle lying near him. This razor was found to be much notched on the edge, while the throat was smoothly and evenly cut from one side to the other, and to the vertebral column. Some considered this to have been an act of suicide, others of murder. Those medical witnesses who supported the view of suicide, were asked to explain how it was that such an even wound could have been produced by a notched razor. They attempted to account for this by asserting that the deceased had probably notched the razor by drawing it backwards and forwards across the neck-bone; forgetting that before this could have been done by the deceased, all the great vessels of the neck must have been completely divided!

3. Blood on weapons.—It does not always happen that the weapon with which a wound has been inflicted is covered with blood. It has been remarked, that in the case of stabs, the knife is frequently without any stains of blood upon it; or there is only a slight film, which, on drying, gives to the surface a yellowish-brown colour. The explanation of this appears to be that the weapon, in being withdrawn, is sometimes cleanly wiped
against the edges of the wound in the integuments. Thus, the first stab through the dress may not present any appearance of blood on the outside, but in a second stab, with the same weapon, the outside of the dress should present a bloody mark, unless the weapon had previously been wiped. The blood may have been removed by washing from the blade of the knife. The handle and inner portions should therefore be closely examined. In a recent case of alleged murder (Nov. 1857), I found no blood on the blade of a knife or in the notch for opening it; but on removing the buck-horn handle, I found a coagulum of blood between this and the plate of iron to which it was riveted.

When a weapon is bloody, particular attention should be given to the manner in which the blood is diffused over it. In cases of imputed wounds, or in the attempted concealment of murder, it is not unusual for a criminal to besmear with blood a knife or other weapon which has probably not been used. A case of this kind occurred to the late Dr. Marc. A young man alleged that he had received a cut on the forehead by a blow from a cutlass, which he produced. It was remarked, that the weapon was smeared with blood on both surfaces; but the layers were thicker towards the handle than at the point. The wound on the forehead was a clean incision; and a cap which the complainant wore had been cut through. It was obvious, therefore, that the blood on the weapon could not have proceeded from this cut; for it would have been wiped, or only left in thin streaks, and more towards the point than the handle, by the act of drawing it through the clothes in producing the wound. There was no doubt that blood had been intentionally applied to the blade. (Ann. d’Hyg. 1829, p. 263.)

The blood on a weapon may be in a partly coagulated state, and not diffused as a mere film. This would render it probable that it had issued from the body of a living person or animal, or from a body recently dead. The blood of a dead animal dried in small spots on the blade of a knife may sometimes present a similar appearance, and thus lead to a mistake in evidence. This question arose in the case of Reg. v. Nation, Taunton Spring Assizes, 1857. Deceased was found dead in a cart with his throat cut, and there could be no doubt that this was an act of murder. The prisoner, who had been last seen in his company, was arrested, and a knife was found in his possession, on the blade of which there were marks of blood. On the part of the prosecution it was contended that the knife had been used for cutting the throat of the deceased, while, according to evidence given for the defence, it had been used for cutting raw meat (beef). Mr. Herapath, who was called for the prosecution, is reported to have stated on oath, that the knife had been immersed in living blood up to the hilt—that it was not the blood of an ox or a sheep, and that there were on the blade of the
knife certain scales or empty cells, such as are found in the mucous membrane of the throat (epithelial scales?). They were much larger than the globules of the blood, and were perfectly distinguishable by the microscope. From the appearance, the knife had passed through the mucous membrane which forms the lining of the throat! If this evidence were trustworthy there was an end to the defence; and with the admission of the statement that there were scales of the mucous membrane of the throat (the gullet?) upon the blade, no further proof was required that the weapon had been used for cutting a throat. Fortunately for the ends of justice, there were other circumstances which brought the crime home to the prisoner, and he was convicted. The evidence of Mr. Herapath on this occasion has been justly condemned by the Editor of the Medical Times and Gazette as "disingenuous claptrap" (April 11th 1857). Mr. Coleridge, counsel for the prisoner, observed that "he (Mr. Herapath) was not so much a professional witness, as a witness by profession, and that he traded in some degree in evidence;" while the learned Chief Justice (Cockburn), in commenting on these microscopic subtleties, said, "Mr. Herapath took upon himself to say it was not the blood of a dead animal. It was living blood, and human blood; and he had shown them the marvellous powers of the modern microscope. At the same time, admitting the advantages of science, they were coming to great niceties indeed, when they speculated upon things almost beyond perception, and he would advise them not to convict upon this scientific speculation alone." It is to be hoped that the jury acted upon the advice of the learned judge; for the reception of evidence of this kind, bearing upon abstruse points of physiology, given by a witness who is not a member of the medical profession, must have a dangerous tendency. It inculcates a rash reliance upon the microscope, and a mode of adapting scientific facts to meet the gaps in circumstantial evidence, which, if the example be followed by professional men, cannot fail to be productive of great evil. Where is the professed physiologist who, in a case of a similar kind, would have avouched on oath a statement that he had discovered the mucous cells or scales of the membrane of the throat on the blade of a knife which, on his own admission, had been plunged up to the hilt in living blood? An educated physiologist would have distrusted his judgment in such matters. Knives of this kind are sometimes held with the open blade in the mouth, and may thus innocently receive epithelial scales from the saliva; but this is, I believe, the first time in a Court of law, in which an attempt has been made to connect a bloody knife or weapon directly with wounds in the throat, by such pseudo-scientific statements.

4. Hair and other substances on weapons.—In some instances no blood may exist on the weapon, but a few hairs or fibres may be found adhering to it if the weapon be of a bruising kind.
The main question will be, in such a case, whether the hair is that of a human being or of an animal. See in reference to this question the case of the Queen v. Teague, Cornwall Summer Assizes, 1851 (Med. Gaz. vol. xlviii. p. 729). The importance of examining closely the hair found on weapons is shown by a case quoted by Dr. Lyons, in which a hatchet having clotted blood and hair adherent to it was produced as evidence against an accused person, under whose bed this weapon had been found. This, with other circumstantial evidence, had turned public opinion strongly against the prisoner, when a physician who happened to be in court, examined the hair with a pocket lens, and pronounced that it was not human, but belonged to some animal. This circumstance led to a more complete sifting of the evidence, and the accused was acquitted. It turned out that he had killed an animal with the hatchet, and had carelessly thrown the weapon under the bed. (Apology for the Microscope, p. 24.) In the case of Reg. v. Hansen (Bodmin Lent Assizes, 1856) the weapon by which the deceased lost his life was a heavy stone found near the dead body. The base of the skull was fractured, and there was upon the stone the marks of blood with some hair similar to that of the deceased. The prisoner was connected with the act by his having been seen with the stone, or one closely resembling it, in his possession. On these and other circumstances he was convicted.

Before any coagulated blood is removed from a weapon it should be examined carefully by the microscope. Hairs or fibres of linen or cotton, or other substances, may be found imbedded in the solidified blood either on the edge or on the blade; and evidence of this kind may occasionally be of great importance. In the case of Reg. v. Harrington, Essex Lent Assizes, 1852, a razor was produced in evidence, with which it was alleged the throat of the deceased had been cut. I examined the edge microscopically, and separated some small fibres from a coagulum of blood, which under a high magnifying power turned out to be cotton fibres. It was proved at the trial that the assassin, in cutting the throat of the deceased while lying asleep, had cut through one of the strings of her cotton nightcap. This was a strong circumstance to show that the razor produced was the weapon with which the fatal wound had been inflicted.

5. Foreign substances in wounds. — In gunshot wounds, the examination of wadding or paper found in a wound or near the body of the deceased has in more than one instance led to the identity of the person who had committed the crime. His hand-writing has been traced on the paper used as wadding, or it has been found to have been part of a printed page, of which the remainder has been discovered in his possession. When a gun is discharged near to the body, a portion of the wadding is generally carried into the large irregular wound
which is produced. This was part of the evidence in the case of Reg. v. Blogg (Chester Summer Assizes, 1857). The peculiar character of the wadding found in the body, connected the prisoner with the act. In a case which occurred at Bramhall, Cheshire, in October 1857, the guilt of the prisoner Henderson, who was charged with the murder of his father by shooting him, rested presumptively on the fact that part of the singed and blackened paper used as wadding, and found about the person of deceased, completed the pages of a book to which the prisoner had access. After he had perpetrated the act, he had discharged a gun on the stairs to give the impression that he was firing at burglars who had broken into the house; but that the same hand had fired both guns was proved by the paper-wadding in each case having been torn from the same book!

Foreign substances may be sometimes discovered in contused or lacerated wounds; and these may throw an important light on the circumstances under which the crime was perpetrated. In the case of the Queen v. Hazell (Taunton Lent Assizes, 1848), the body of the deceased was found in a well. When examined, there were on the head several severe wounds quite sufficient to account for death. There was much blood on the clothes and face, and in the blood were sticking a quantity of hay-seeds, which led the medical witnesses to consider that the wound must have been inflicted in a stable or in some place where there was hay. On examining a neighbouring stable, the spot where the murder was committed was rendered evident by the discovery of marks of blood.

There may be found in the wound a portion of the weapon. The preservation of this is important, as it may serve to connect the prisoner with the act, should his criminality be otherwise doubtful. In the case of Reg. v. De Salvi (C. C. C. October 1857), it was proved that the deceased died from a stab inflicted on him by the prisoner. Two inches of the pointed portion of the blade of a knife were found imbedded in one of the vertebrae. The spinal cord had been divided, and paralysis ending fatally, was a result of the wound. The identity of the weapon was not only established, but the force with which it had been used by the prisoner was clearly indicated.

6. Marks of blood on clothing or furniture.—It is proper to notice all marks of blood on the clothes of the deceased or in the apartment, and observe where the greatest quantity of blood has been effused; this is generally found in the spot where the deceased has died. The deceased may have bled in more places than one; if so, it becomes important to notice whether there be any communication in blood between these different places. Blood on distant clothes or furniture will show whether the deceased has moved about, and whether he has struggled much after receiving the wound. Acts of locomotion by a wounded
person who has died from loss of blood, or by a criminal whose hands and feet may be bloody, are generally indicated by tracks or marks of blood. The observation of these marks is of medical importance at the time that a dead body is found. They may be so situated as to show that the body has been moved or been interfered with after death, and thus throw a light upon the question whether the act has been one of homicide or suicide. In the case of Reg. v Hatto (Bucks Lent Ass., 1854), a mark of blood, as from the smear of a hand, was traced along a passage of the house in which the body of the deceased was found. The mark was continued over the door-post into a back room, which was found locked and bolted on the inside. The crime was thus fixed upon the prisoner; for no one breaking into the house in front could have had access to this room. The evidence thus brought against him was derived from his feeling his way with a bloody hand in the darkness after the murder. He was not at the time aware that he was thus leaving impressions which would show that no one but himself could have perpetrated the crime. It is a fair subject of medico-legal inquiry on these occasions, whether there are any marks of blood about the apartment, which no one but the assassin could have produced.

It is advisable, if it be possible, to have some clear proof that the clothes sent for examination were actually worn by the accused, or belonged to the deceased. Serious mistakes are sometimes made, and opinions should therefore be expressed with caution. In the case of Hatto (Bucks Lent Assizes, 1854), the clothes said to have been worn by the prisoner on the night of the murder were sent to me for examination. On the shirt there were no marks of blood; on the trousers and cap there were a few stains of blood; but it was admitted that, from the appearance of these, they might have been on the clothes five or six weeks, and therefore several weeks prior to the date of the murder. Owing to this want of certainty respecting date, the clothes were not produced in evidence; and it subsequently turned out by the confession of the prisoner, and the discovery of other articles of dress in places where he admitted he had concealed them, that those which had been examined were not the clothes worn by him when he perpetrated the murder! In the case of Reg. v. Munro (Cumberland Spring Assizes, 1855), the clothes supposed to have been worn by the prisoner were also sent to me for examination. There was no blood on the trousers, and it appeared from the evidence given at the trial that the prisoner had changed this article of dress.

We must observe likewise, whether, if the wound be in the throat or chest, blood has flowed down in front of the clothes or person, or whether it has flowed so as to collect in the armpits; for these appearances will sometimes show whether the wound was inflicted when the individual was standing, sitting, or lying down.
If the throat be cut while a person is lying down, it is obvious that the blood will be found chiefly on either side of the neck, and not extending down the front of the body. Few suicides cut the throat while in a recumbent posture, and the course which the blood has taken may, therefore, be sometimes rendered subservient to the distinction of a homicidal from a suicidal wound. The position in which the body was, when the wound was inflicted, is a frequent question on inquests and criminal trials. In the case of Lord William Russell (Reg. v. Courvoisier, C.C.C. 1840), the throat had evidently been cut while the deceased was lying in bed; the blood was diffused on each side of the neck only. There was also found a wound on the thumb of the right hand of the deceased, which was probably inflicted at the time the hand was put up to defend the throat. Recent wounds on the back of one or both hands, when found in persons who have died from wounds in the throat, are, ceteris paribus, strongly presumptive of homicide. There may, however, be no marks of wounds on the back of the hands, if the individual was attacked unexpectedly—if he was intoxicated, or rendered powerless, or if several had combined to attack him, while he was pinioned and held by an accomplice.

If the deceased had been wounded with his clothes on, we should notice whether any part of his dress has or has not been cut or injured over the situation of the wound:—whether the cut portions of dress are bloody, and whether the blood has been diffused or applied on the inside or outside. When, together with a wound in the throat, we find the cravat and the shirt, or part of the dress, cut through, this is, all other circumstances being equal, strongly presumptive of homicide; for it is not usual that a suicide, unless labouring under confirmed insanity, would allow any mechanical obstacles of this kind to remain as an obstruction to the use of a weapon. In a case of homicidal wound of the throat, inflicted in the recumbent posture, the cravat of the deceased had been lifted up, and afterwards allowed to drop over the wound in order to conceal it. The importance of examining the dress, and comparing it with the marks of violence on the body, has already been pointed out. (See case by Mr. Codd, ante, p. 259.)

The nature of the dried spots of mud on clothing may occasionally serve to connect an accused person with an act of murder. In the case of the Queen v. Snipe and others (York Winter Assizes, 1852), evidence was adduced to show that some spots of mud on the boots and clothes of the prisoner, when examined microscopically, presented infusorial shells, and some rare aquatic vegetables, particles of soap, coniferous, and hairs from the seeds of groundsel. The mud of a ditch close to which the body of the deceased was found, presented the same appearances precisely as the mud on the prisoner’s boots: and
the witness who gave this scientific evidence, deposed that in
his opinion the mud-spots were derived from this ditch. He
had examined the mud of all the other ditches in the locality,
and found it to be different. Admitting the opinion to have
been correct, this circumstance clearly connected the prisoner
with the act; and it was borne out by the fact that he had been
seen near the spot on the night of the murder. In a recent case
(Nov. 1857) I found granules of wheat-starch mixed with the
blood-stains on the gaiters of a man charged with murder. He
had been just before the occurrence engaged in sowing seed-
corn.

7. Marks of blood on the person.—All marks or stains of blood
on the body of the deceased require special observation. Very
often the impression of a hand, or of some of the fingers, will be
found on the skin in a situation where it would have been
improbable or impossible for the deceased to have produced it,
even supposing that one or both of his hands were covered with
blood. In one case of murder, there was found the bloody im-
pression of a left hand upon the left hand of the deceased, in
such a position, that it was quite impossible the deceased him-
self could have made the mark! In all cases it is proper to
notice whether the inside or outside of the hand, or whether one
or both hands, be marked with blood, and to describe the size
and position of the marks. Stains of blood on the dress of a
wounded person may often furnish important circumstantial
evidence. If there be several stabs or cuts on the body involving
the dress, it should be observed whether the edge of one or more
of them be stained with blood, as if from the wiping of a
weapon, and whether the stain be on the outside or inside of the
article of dress (ante, p. 279). In simulated personal in-
juries, the stain of blood may be, through inadvertence, applied to
the outside of the dress—a fact which might, in some instances,
lead to the detection of the imposture. (See case by Dr.
Bayard, Ann. d’Hyg. 1847, ii. 219.) In judging from marks of
blood in the apartment, we must take care that we are not
unconsciously misled by the accidental diffusion of this liquid by
persons going in and out. The following case, which will show
the necessity of extreme caution, occurred in France. A young
man was found dead in his bedchamber with three wounds on the
front of his neck. The physician who was first called to see the
decedent had, unknowingly, stained in the blood with which the
floor was covered, and had then walked into an adjoining room,
passing and repassing several times; he had thus left a number of
bloody foot-prints on the floor. No notice was taken of this
at the time; but on the following day, when the examination
was resumed, the circumstance of the foot-prints was particularly
attended to, and excited a suspicion that the young man had been
murdered. The suspected person was arrested, and would have
undergone a trial on the charge of murder, had not M. Marc been
called in to examine all the particulars of the case. A similar
circumstance occurred in the case of Eliza Grimwood, who was
murdered at Lambeth in June 1838.

8. Arterial distinguished from venous blood.—It is not possible
to distinguish arterial from venous blood by any physical or
chemical characters, when it has been for some days effused, and
has fallen upon articles of dress or furniture: but this, in medico-
legal practice, is not often a subject of much importance, since
there are few cases of severe wounds, either in the throat or
other parts of the body, in which the two kinds of blood do
not escape simultaneously. The most striking and apparent
difference between them, when recently effused, is the colour.
the arterial being of a bright scarlet, while the venous is of a
dark red hue; but it is well known that the latter, when exposed
to air for a short time, acquires a florid red or arterial colour:
and the two kinds of blood, when dried, cannot be distinguished
by any known criterion. If the coat or other stuff, covered with
blood, were of a dark colour, the liquid would be absorbed, and
lose its physical characters. Arterial blood contains more fibrin
than venous, and coagulates more firmly. Even the microscope
shows no appreciable difference in the blood-corpuscles; and
chemistry does not enable us to apply any test so as to make a
satisfactory distinction between them. In this deficiency of
microscopical and chemical evidence, an attempt has been made
to establish a distinction by noticing the physical appearances of
the blood-stains. Thus, it is alleged, the arterial blood will be
indicated by its being sprinkled over surfaces upon which it has
fallen, while the venous blood is always poured out in a full
stream. In most wounds which prove fatal by haemorrhage, the
blood is poured out simultaneously from arteries and veins.
The sprinkled appearance of blood, when it exists, will, ceteris
paribus, create a very strong presumption that it was poured out
from a living body; for, after the heart has ceased to act, the
arteries lose the power of throwing out the blood in jets. This
mode of distinguishing arterial from venous blood was adduced as
evidence in the case of Sellis, who destroyed himself after having
attempted to assassinate the Duke of Cumberland. There was
the appearance of sprinkled blood on the coat-sleeve of Sellis, and
the temporal artery of the Duke had been wounded in the struggle.
Sir Everard Home thence inferred that Sellis had attacked
the Duke, and wounded the artery, which had led to the sprink-
ling of the sleeve. (Will’s Circ. Ev. 98.) This method of dis-
tinguishing the two kinds of blood, therefore, may be occasion-
ally available for practical purposes; but it must be remembered
that accident may lead to the sprinkling of blood from a small
vein which has been wounded, while blood may be poured out
in considerable quantity from an artery, especially if large; and
if it fall on one spot at a short distance, it may produce a soaked
appearance. The sprinkling may be expected only when the wounded artery is small, and the blood is effused at a distance. This is a fact which a medical jurist should not overlook, although, for the reasons stated, too great a reliance must not be placed on it. The blood, if thrown out from a living blood-vessel, very speedily consolidates in small spots; and the fibrin, with the greater portion of the colouring matter, is found of a deep red colour at the lower part of the spot, the upper portion being of a pale red. The lower and thicker part has commonly a shining lustre, as if gummed, when the spot is recent, and when it has been effused upon a non-absorbent surface. The glazed appearance is probably given by the evaporation of the aqueous, and the rapid desiccation of the albuminous portion. When the blood falls upon porous articles of clothing, as linen or cotton, it is absorbed and produces a dull stain. In dark-coloured articles of dress, it is difficult by daylight to perceive these stains. The part appears stiffened, and there is a dull red-brown colour, which is sometimes more perceptible when seen by the reflection of the light of a candle. Stains of tobacco, or of the juices of certain vegetables, may present the appearance of those of blood. Such mistakes frequently occur. The distinction between them will, however, be rendered immediately apparent by the application of the microscope and of the chemical processes to be hereafter mentioned. (See Blood-stains.)

In trusting to the coagulation of the blood as evidence of its escape from a living vessel, it must be remembered that there are certain diseases, as scurvy and typhus, in which, owing to morbid causes, the blood does not readily coagulate: while, again, some hours elapse before it coagulates in the healthy body after death. Hence blood which has escaped from a recently dead body, although it would not be found diffused as if by spitting, might, in so far as coagulation is concerned, assume the appearance of having been effused from a living body. (See case of Reg. v. Nation, ante, page 279.) On this fact Donné has founded a process for determining whether a person is really dead. (Cours de Microscopic, p. 54.)

When spots of blood are found upon articles of dress or furniture, their form and direction may sometimes serve to furnish an indication of the position of the person with respect to them when the wound was inflicted. Thus, if the form of a spot is oval and elongated, the presumption is that the person was placed obliquely with respect to the stained furniture, during the hemorrhage. (Ann. d’Hyg. 1840, p. 397.) The impetus with which the blood has been thrown out, will be in some measure indicated by the degree of obliquity and length of the spot. This is in general wide and rounded at the upper part but narrow and pointed below. The case of Spicer (ante, page 271) furnishes some suggestions on the importance of evidence occasionally derived from the examination of the form and direction taken by spots.
of blood. At the top of the stair, and at the height of four or five feet above the level, several spots of blood were observed upon the brick wall. These were rendered very evident by the wall having been recently white-washed. The spots took an oblique direction from above downwards, were of a pale red colour at the upper part, but dark red below, terminating in a point consisting of the fibrin and the greater part of the red colouring matter. Their form and regularity proved that they had proceeded from a small artery, and that the wounded individual could not have been very distant from the wall, while their shining lustre rendered it probable that they were of recent origin, and their well-defined termination in a firm coagulum, showed that they had probably proceeded from a living blood-vessel. The deceased had died from fracture of the skull and vertebral column by a fall from the top-stair: one branch of the right temporal artery was found divided, and this wound could not have been produced by the fall. It was therefore evident that a murderous assault had been made upon the deceased at the top of the stair, and this had led to the spitting of the arterial blood on the brick. The height at which the spots existed, and their appearance, proved that the jet of blood had been from above downwards; thereby rendering it probable that the deceased was standing up, or that her head was raised at the time the wound was inflicted. Further, as the brick with the spots was on the left hand in the descent, and the wounded artery was on the right side, it is probable that the deceased was face to face with her assailant in the act of ascending the stairs, and that she was killed by being precipitated backwards to the bottom. The position in which the body was found in the cellar corroborated this view. (See Med. Gaz. xxxvii. p. 612.)

**Inspection.**—In examining a dead body, it is proper that attention should be paid to the state of the *mouth* and *throat*. Assassins who make their attack during sleep, sometimes endeavour to close the mouth, or to compress the throat, so as to prevent an alarm from being given. In the case of the *Duchess of Praslin*, there were the marks of finger nails around the mouth. In another instance, ecchymosed impressions, as if produced by a hand, were found upon the throat of the deceased. The *hands* of the deceased should always be examined; many cuts, excoriations, or incisions, found upon them, especially if on the dorsal surface (back), will indicate that there has been a mortal struggle with the assailant. In the inspection, the examination of the *stomach* should not be omitted. The presence or absence of food, mucus, or blood, may furnish evidence of considerable importance in the elucidation of the case. Thus, in the stomach of the *Duchess of Praslin*, a quantity of bloody froth was discovered. This rendered it certain that she had lived sufficiently long to swallow a quantity of saliva mixed with blood, and that probably she had
made some attempts to give an alarm. The fact that several days have elapsed since death, will not prevent the discovery of food in the stomach, provided it has been taken within one or two hours before death; since the digestion of food does not appear to go on to any perceptible extent after death. I have thus discovered food in the stomach twenty-eight days after interment. This question connected with the digested or undigested state of the food found in the stomach, very frequently arises on criminal trials. (See Spicer's case, ante, p. 271.)

CHAPTER XXV.

DISTINCTION OF SUICIDAL FROM ACCIDENTAL WOUNDS—IMPORTANT IN CASES OF LIFE-INSURANCE—WOUNDS ON THE THROAT—FACTS INDICATIVE OF SUICIDE, HOMICIDE, OR ACCIDENT—IMPUTED OR SELF-INFLICTED WOUNDS—MOTIVES FOR THEIR PRODUCTION—CHARACTERS OF IMPUTED WOUNDS—RULES FOR DETECTING FALSE CHARGES OF MURDER.

Suicidal wounds.—It is not often that any difficulty is experienced in distinguishing a suicidal from an accidental wound. When the wound has really been suicidally inflicted, there are generally to be found about it very clear indications of design; and the whole of the circumstances are seldom reconcilable with the supposition of accident. But if the position of the deceased with respect to surrounding objects has been disturbed, if the weapon has been removed, and the body transported to a distance, then it will not always be easy to distinguish a wound accidentally received, from one inflicted by a suicide or a murderer. The evidence of those who find the body can alone clear up the case; and the medical witness may be required to state how far this evidence is consistent with the situation, extent, and direction of the wound by which the deceased has fallen. It is unnecessary to dwell further on this subject, since the observations made in the preceding pages will suggest to the practitioner the course which he has to pursue. Circumstantial evidence is commonly sufficient to show whether a wound has been accidentally received or not; but as an accidental wound may sometimes resemble one of homicidal or suicidal origin, so it follows that it is not always possible for a medical jurist to decide the question peremptorily from a mere inspection of the wound. Homicide is only liable to be confounded with accident in relation to contused and contused wounds. In cuts and stabs, the evidence of design will be in general too apparent to allow of any doubt being entertained respecting the real origin of the injury. It would not be difficult to produce many instances in which murderers, in their defence, have alleged that the wounds observed in the
bodies of their victims were of accidental origin, and the allegations have been clearly refuted by medical evidence. A witness must be prepared, therefore, in all cases in which death has taken place in secrecy, and the nature of the wound is such as to render its origin doubtful, to be closely examined by counsel for a prisoner charged with felonious homicide, on the question whether the wound might or might not have been accidental. Our law requires that it should be rendered evident to a jury, before such a charge can be sustained, that the fatal wound could not have been accidental or suicidal. Hence this preliminary question is deserving of the attention of a medical jurist.

The death of a person from wounds has hitherto been considered as a subject connected with a criminal charge; but an investigation of the circumstances under which death ensues, is occasionally rendered necessary when the deceased has effected an insurance upon his life. A policy of life-insurance is in some cases rendered void by the act of self-destruction; and therefore an individual bent on suicide might, for the sake of his family, take precautions to conceal the manner in which he intended to destroy himself. His body might be found wounded in a manner which would render it uncertain whether he had been wounded accidentally, whether he had been murdered, or whether he had fallen by his own hand. In a disputed case, it is incumbent on the Office to prove the act of suicide (felo de se), while the relatives of the deceased would attempt to show the contrary. Such litigation must, of course, call forth a searching investigation into all the circumstances connected with the death of an insured party, and the whole case would, in some instances, at least, rest almost exclusively on medical evidence. (Med. Gaz. xxxvi. 826.) Numerous cases have of late years occurred in England, which illustrate the importance of attending to the precise characters of wounds, and the circumstances under which the body of a wounded person is found. The following may serve as an illustration:

Wounds of the throat. Suicide or homicide?—In the year 1837, the late Mr. Dodd, of Chichester, consulted me on the following case:—He was called to examine the body of a woman, who was found dead with her throat cut. The deceased, when seen by him, was lying on her back, and the razor with which the wound was inflicted, was found under the left shoulder. On inquiry, it was ascertained that, when first seen, she was lying on her face, and the body had been turned round on the back. Blood had evidently run down the fore-part of her person, rendering it probable that she had been wounded while in the erect position. The incision in the throat was deep, and extended obliquely from the right side of the chin, to within about an inch of the left collar-bone. It had divided the wind-pipe, the gullet, all the muscles of that side of the fore-part of the neck,—the carotid artery, jugular vein, and the muscles on the fore part of the
IMPUTED OR SELF-INFlicted WOUNDS.

spine, penetrating even into the bodies of the cervical vertebrae. The incision was double,—one superficial, close under the chin, and the other, the deeper one, appeared to be continued from this. The deepest part of the right end of the incision was nearly three inches in a direct line behind the right angle of the wound, so that it extended at that part behind and beneath the sound skin. The cut was four and a half inches long, and two and a half deep. The main question was, whether this could have been a suicidal wound, inflicted by a razor, the only weapon found near the body. Considering its characters, Mr. Dodd inferred that it must have been inflicted by another person, and not by the deceased upon herself. The deceased was right-handed, which would have added to the difficulty of supposing the wound to have been suicidal. The inference drawn was precisely that which the medical circumstances appeared to me to justify.

Imputed or self-inflicted wounds.—The question whether a wound was or was not self-inflicted, may refer to the living as well as to the dead. Thus a man may produce wounds upon himself for the purpose of simulating a homicidal assault, which, for various motives, he may allege to have been committed upon him. With the motives for the self-infliction of wounds, a medical jurist is not concerned,—it is of the fact only that he can take cognizance. From the cases that have yet occurred, it would appear that the object has been to extort money, to conceal murder, robbery, or some other crime, and to turn away suspicion from the wounded party. One of the most remarkable cases of this kind which have occurred in England, was that of Bolam, who was tried for the murder of a man named Millie, at the Newcastle Autumn Assizes, 1839. It is impossible to enter into all the particulars of this singular trial; but it may suffice to state that the prisoner Bolam was found lying in an apartment which had been fired by himself or, as he alleged, by some incendiary, and near him was the body of the deceased, who had evidently been killed by violence,—the skull having been extensively fractured by a poker lying near. The prisoner, when found, was either insensible or pretended to be so. He stated that he had been suddenly attacked by a man, and knocked down by a blow on the right temple. After attempting to escape, he was again knocked down. He then felt a knife at his throat, but admitted that he did not put up his hands to protect it. His hands were not cut. He said he remembered receiving some blows on his body, but he became insensible, and recollected nothing more. On examining his throat, there was a wound an inch and a half in length on the left side of the neck, a quarter of an inch below the jaw. It had penetrated merely through the true skin, and was of inconsiderable extent. A small quantity of blood, which had flowed down on the inside of his cravat, had escaped from this wound.
There were many cuts on his coat at the back and sides, through his waistcoat, shirt, and flannel shirt; but there were no corresponding cuts or stabs, nor, indeed, any mark of injury upon the skin. The question was, whether these wounds had been inflicted by the unknown person who was alleged to have fired the premises and murdered the deceased, or whether the prisoner had inflicted them on himself, in order to divert attention and conceal the crime which he was accused of having committed. No motive for the imputed crime was discovered, and he had borne a very good character; but, nevertheless, the medical facts relative to the probable self-infliction of the wounds were so strong, that he was convicted of manslaughter. There was no doubt that the prisoner produced the wounds upon himself in order to remove from himself the suspicion that he had caused the death of the deceased. They were superficial, involved no important organs, and bore the characters which those wounds only would have, that had not been produced with a suicidal intention.

Soon after Bolam’s case, one somewhat similar occurred in this metropolis. The steward of a club-house was found one morning in bed wounded, and the cash-box of the club was missing. Circumstances led the police to suspect that no one could have broken into the house; but the man himself was considered so trustworthy, that no suspicion was entertained of his having been concerned in the robbery. The surgeon who examined him found the wounds on his person of a very trivial character; and there was no doubt, from what subsequently transpired, that he had produced them on himself for the purpose of avert ing suspicion.

It is not always easy to trace the motive for the production of these injuries; and when a reasonable motive is not immediately discovered, persons are very apt to be misled and to credit the story. Individuals who have been convicted of thus imputing violence to others have frequently borne a respectable character until the occurrence, and this has contributed to disarm suspicion. When a person intending to commit suicide fails in the attempt, he has sometimes, under a sense of shame, attributed the infliction of a wound in his throat to another; but facts of this kind may be without difficulty cleared up by circumstantial evidence. Imputed wounds, if we except the case of an actual attempt at suicide, in which the injury is commonly severe, are generally of a superficial character, consisting of cuts or incisions not extending below the true skin:—deep stabs are seldom resorted to where the purpose is not suicide, but merely to conceal other crimes. Further, these wounds are in front of the person, and may be on the right or left side, according to whether the person be right or left-handed. They have also been generally numerous, and widely scattered: sometimes they have had a complete parallellism, unlike those which must have been inflicted by an adversary during
CORRESPONDING CUTS ON THE DRESS. 293

a mortal conflict with a weapon. The hands are seldom wounded, although in the resistance to real homicidal attempts these parts commonly suffer most severely. The injuries are not usually situated over those parts of the body in which wounds are by common repute considered mortal, and there is in general an entire want of correspondence between the situation of the wounds on the person, and the cuts or other marks on the dress. This is an important fact, which requires the attention of a practitioner. In an interesting case which occurred to Marc, a young man alleged that he had received a sword-cut on the forehead from some assassins who had escaped. He was allowed to relate the whole of the particulars, and they formed a very romantic and improbable story. He stated that he wore at the time a handkerchief round his head, a cotton cap, and a common cap with an elastic front, which he alleged had been cut through. There was a longitudinal wound, quite superficial and about an inch long, at the upper and right part of the frontal bone, passing downwards from left to right. The cut in the felt of the cap, which was very soft, passed obliquely from right to left, and was about three inches in length. The cut was not so clean or regular as if it had been produced by a sword: there was very little blood upon the cap, and only on the edge of the incision. The silk handkerchief was cut in an irregular manner. When the party was requested to place the cap and other articles upon his head in the position in which he stated they were when he was attacked, it was found to be utterly impossible to adjust them,—the incisions could not be made to correspond, and the cap could not be worn over the folded handkerchief. This rendered it certain that the wound had not been inflicted in the manner described. Besides, a blow of a sword which would have divided the felt and silk handkerchief, would at the same time have produced a much deeper wound on the forehead than that which was found. (Ante, p. 279.) Another instructive case is reported by Dr. Bayard, in which the falsehood of a charge was demonstrated by the want of correspondence between the cuts in the clothes and those found on the person. (Ann. d’Hyg. 1847, ii. 222.)

In comparing cuts on the dress with wounds on the person, there are several circumstances to be attended to. What articles of dress were worn at the time of the assault? In a case of stabbing all ought to present marks of perforation, corresponding in direction, form, size, sharpness of the edges of the weapon, &c. In imputed wounds, the marks on several layers of dress may not correspond with each other in the characters above mentioned. It is very difficult for a man simulating such injuries so to arrange his clothes when off his person, as to deceive an examiner. There will be some inconsistency or want of adjustment. Apart from the fact that several stabs or cuts cannot exist on the same part of the clothes, without one or more being stained.
IMPUTED WOUNDS.

with blood on the outside or inside, an impostor may do too much or too little, and thus lead to his detection. In a case which excited much public discussion, a very simple circumstance led to the inference that certain stabs or cuts through a shirt had not been produced while the shirt was on, but while it was off the body. There were two cuts near to each other, precisely similar in size, form, and direction. In fact, the knife or dagger producing them must have gone through a fold of the shirt, so accurate was the correspondence. Then, however, it followed that the shirt could not have been upon the body of the alleged wounded person, because a stab through a shirt when worn, must, in order to reach the body, traverse not only a fold (producing two cuts), but another layer in contact with the skin, and thus produce three cuts, or in the event of traversing two folds, five cuts. In simulating the wounds by cuts on the shirt, the person is supposed to have forgotten this, and have merely stabbed a fold of the shirt while lying on a table, or in some situation convenient for the purpose. This, among other facts, rendered it probable that the slight wounds on the chest were self-inflicted.

It has been contended that no rules can be laid down for the detection of such cases: each must be decided by the facts which accompany it. Nevertheless, the details of the cases above mentioned will serve to direct the inquiries of a practitioner. The facts which he must endeavour to ascertain are the following:—1. The relative positions of the assailant and the assaulted person at the time of the alleged attack. 2. The situation, direction, and depth of the wound or wounds. 3. The situation or direction of marks of blood or wounds on the person or dress of either, or of both, the assailant and assaulted. 4. The marks of blood, and the quantity effused at the spot where the mortal struggle is alleged to have taken place. The importance of these inquiries cannot be over-estimated. A strong suspicion was raised against the late Duke of Cumberland, in the year 1810, in reference to the death of Sellis, when a proper examination of the wounds would probably have shown that they could not have been self-inflicted.

It is worthy of remark, that imputed wounds are generally cuts or stabs. They are seldom of the contused kind; the impostor cannot, in reference to contusions, so easily calculate upon the amount of mischief which is likely to ensue. Pistol-shot wounds are sometimes voluntarily inflicted for the purpose of imputing murder or extorting charity. A man intending to commit suicide by fire-arms, and failing in the attempt, may, out of shame, in order to conceal his act, attribute the wound to the hand of some assassin. In examining such imputed wounds they will not be found (except in cases of attempted suicide) to involve vital parts; and they will possess all the characters of
narrow-wounds produced by gunpowder, wadding, or a bullet. (See Gun-shot Wounds.) The skin around will be extensively lacerated and bruised: there will be much ecchymosis, and the hand holding the weapon, as well as the dress and the wounded skin, may be blackened or burnt by the exploded gunpowder. A pistol-shot wound from an assassin may be produced from a distance, while an imputed wound which is produced by a person on himself, must always partake of the characters of a near-wound. If the weapon have been charged with gun-cotton, there will be no marks of blackening on the person or dress, but there may be marks of burning.

CHAPTER XXVI.

THE CAUSE OF DEATH IN WOUNDS—CAUTION ON ASSIGNING TOO MANY CAUSES—WOUNDS DIRECTLY OR INDIRECTLY FATAL—DEATH FROM HEMORRHAGE—LOSS OF BLOOD REQUIRED TO PROVE FATAL—MODIFIED BY AGE AND OTHER CIRCUMSTANCES—FATAL WOUNDS OF SMALL ARTERIES—INTERNAL HEMORRHAGE—DEATH FROM MECHANICAL INJURY TO A VITAL ORGAN—DEATH FROM SHOCK—BLOWS ON THE ABDOMEN—FLAGELLATION—DEATH FROM A MULTIPlicity OF INJURIES WITHOUT ANY MORTAL WOUND—SUBTLE DISTINCTIONS RESPECTING THE MORTALITY OF WOUNDS.

Cause of death.—It is important for a medical witness to bear in mind that in all cases of wounds criminally inflicted, the cause of death must be certain. No man is ever convicted upon mere medical probability. In general there is only one real cause of death, although other circumstances may have assisted in bringing about a fatal result. Thus a person cannot die of a disease in the bowels and a stab in the chest at the same time, nor of apoplexy from disease and compression of the spinal marrow at the same instant. Hence it is our duty, when several apparent causes for death exist, to determine which was the real cause; and in stating it to the Court, to be prepared to offer our reasons for this opinion. In most cases of local injury, when a person dies speedily, there will be no great trouble in settling whether disease or the injury was the cause. A difficulty may, however, exist when a person has recovered from the first effects of a wound, and has subsequently died. Besides, there may be cases in which the cause of death, in spite of the most careful deliberation, will be still obscure; or sometimes it may happen that the death of a party appears to be as much dependent on bodily disease as on an injury proved to have been received at the time he was labouring under disease. How is an opinion to be expressed in
such a case? The course which I apprehend a medical witness ought to pursue, provided he has duly deliberated on the circumstances before he appears in Court, and his mind is equally balanced between the two causes, is to state at once his doubt to the jury without circumlocution, and not allow it to be extracted from him by an adverse cross-examination. It is the hesitating to assign a satisfactory cause, or the assigning of many causes for death, that gives such advantage to a prisoner’s case, even when the general evidence is entirely against him. Occasionally many causes of death are assigned by a witness, among which some have a tendency to exculpate and others to inculpate the prisoner in a greater or less degree, and it is left to the jury to select from the number, one upon which to found a verdict! In a case of this kind an acquittal is commonly obtained.

Wounds directly or indirectly fatal.—A wound may cause death either directly or indirectly. A wound operates as a direct cause of death when the person dies either immediately, or very soon after its infliction; and there is no other cause, internally or externally, to account for death. In wounds which cause death indirectly, it is assumed that the deceased survives for a certain period, and that the wound is followed by inflammation, suppuration, gangrene, tetanus, erysipelas, or some other mortal disease, which is a direct and not an unusual consequence of the injury. Under this head may be also arranged all those cases which prove fatal by reason of surgical operations rendered imperatively necessary for the treatment of the injury,—presuming that these operations have been performed with ordinary skill and care. We shall for the present consider only the direct causes of death in cases of wounds. They are three in number:—1. Hemorrhage, or loss of blood. 2. Great mechanical injury done to an organ important to life. 3. Shock, or concussion, affecting the brain or spinal marrow, whereby the functions of one or more vital organs are arrested, sometimes with but very slight injury to the part struck or wounded. From either of these causes, a wounded person may die immediately or within a few minutes.

1. Death from hemorrhage.—Loss of blood operates by producing fatal syncope. A quantity of blood escaping from a vessel, although insufficient to cause death by affecting the heart and circulation, may readily destroy life by disturbing the functions of the organ or part into which it is effused. Thus a small quantity poured out in or upon the substance of the brain, or at its base, may kill by inducing fatal compression; and again, if, in a case of wounded throat, blood should flow into the trachea, it may cause death by asphyxia — i.e. by stopping the respiratory process. In these cases it is obvious that the blood acts mechanically; and in respect to the last, a medical man may, unless circumpection be used, involve himself in a charge of malapraaxis. If he allow the wound to remain open, the wounded
person may die through haemorrhage,—if he close it too soon, he may die through suffocation; and, in either case, the counsel for the prisoner will not fail to take advantage of a plausible objection of this kind. In wounds of the chest, involving the heart and lungs, death is very frequently due not so much to the actual quantity of blood effused, as to the pressure which it produces upon these organs. A few ounces effused in the cavity of the membrane including the heart, will entirely arrest the action of this organ.

The absolute quantity of blood required to be lost in order to prove fatal, must, of course, vary according to numerous circumstances. The young, the aged—they who are labouring under infirmity or disease, will perish sooner from haemorrhage than others who are healthy and vigorous. Females, ceteris paribus, are more speedily destroyed by haemorrhage than males. Infants are liable to die from haemorrhage resulting from very slight wounds. An infant has been known to bleed to death from the bite of a single leech, or from the simple operation of lancing the gums. Even the healthy and vigorous, when their vital powers have been depressed by maltreatment or by brutal violence, will sink under the loss of a comparatively small quantity of blood. (See Watson on Homicide, p. 90.) A medical jurist must not forget that some individuals have a predisposition to haemorrhage; and this condition is often hereditary. The slightest wound or puncture,—the bite of a leech or the extraction of a tooth, will be attended with a loss of blood which cannot be arrested, and which will slowly lead to death by exhaustion. Cases have been frequently recorded in our medical journals of fatal haemorrhage following the extraction of teeth, when there had been previously nothing to indicate the probable occurrence of death from so trivial a cause. (For striking instances of this remarkable tendency to haemorrhage in a family, see Brit. and For. Med. Rev. xvii. 247; also Med. Gaz. May 1842.) In the thirty-ninth volume of the latter journal, p. 86, a case is reported by Mr. Druitt, in which an unusual degree of haemorrhage followed a compound fracture of the leg. Such cases are without difficulty detected; since a surgeon may always infer from the part injured and the extent of the injury, whether the bleeding is likely to be copious or not. When a person bleeds to death from what would, under common circumstances, be a simple wound, the admission of this fact may in certain cases lessen the responsibility of an accused party.

A sudden loss of blood has a much more serious influence than the same quantity lost slowly. A person may fall into a mortal syncope from a quantity of blood lost in a few seconds, which he would have been able to bear without sinking had it escaped slowly. This is the reason why the wound of an artery proves so much more rapidly fatal than that of a vein. Death speedily
follows the wound of a large artery like the carotid; but it takes place with equal certainty, although more slowly, from wounds of smaller arteries. In a case in which one of the intercostal arteries was wounded by a small shot, haemorrhage caused death in thirty-eight hours. The haemorrhage which follows the division of the smaller branches of the external carotid artery, is often sufficient to destroy life unless timely assistance be rendered. A case was tried at the Berkshire Spring Assizes, 1832, in which it was proved that the prisoner had killed his wife by stabbing her in the leg: the anterior tibial artery was divided, and she died from haemorrhage half an hour afterwards. Wounds of arteries, even smaller than these, might in some subjects prove fatal, if no assistance were at hand. Mr. Watson mentions a case in which the internal mammary artery on the left side was divided by a stab in the chest. The woman died on the ninth day, and four pounds of blood were found effused on that side. In another case in which an intercostal artery was divided, six pounds of blood were effused. (Op. cit. 101.) In both cases, as in most wounds of the chest, the blood not only affected the system by its loss, but by its compressing the lungs and impeding respiration. Wounds of large veins, such as the jugular, may, from the quantity of blood suddenly effused, speedily destroy life. If a wound be in a very vascular part, although no vessel of any importance be divided, the person may die from haemorrhage. It is difficult to say what quantity of blood should be lost, in order that a wound may prove fatal by haemorrhage. The whole quantity contained in the body of an adult is calculated at about one-fifth of its weight — i.e. about thirty pounds: of this, one-fourth is considered to be arterial, and the remaining three-fourths venous blood. According to Mr. Watson, the loss of from five to eight pounds is sufficient to prove fatal to adults. But while this may be near the truth, many persons will die from a much smaller quantity; the rapidity with which the effusion takes place having a very considerable influence. It has been found, by experiment, that a dog cannot bear the loss of more blood than is equivalent to one-twelfth part of the weight of its body.

Internal haemorrhage.—Haemorrhage may prove fatal, although the blood does not escape from the body. In incised wounds, the flow externally is commonly abundant; but in punctured and gun-shot wounds, the effusion may take place internally, and rapidly cause death. In severe contusions or contused wounds, involving highly vascular parts, the effusion may go on to an extent to prove fatal, either in the cavities of the body or throughout the cellular membrane and parts adjacent. Many pounds of blood may thus be slowly or rapidly effused. The means of ascertaining whether a person has died from haemorrhage, are these: — Unless the wound be situated in a very vascular part, we shall
find the vessel or vessels from which the blood has issued, divided, —the neighbouring vessels empty, and the body more or less pallid; although this last condition is of course liable to be met with in certain cases of disease, as also under copious venesection,—points easily determined by an examination. The blood will commonly be found more or less clotted or coagulated on those surfaces on which it has fallen. If, with these signs, there is an absence of disease likely to prove rapidly fatal, and no other probable cause of death be apparent, it may be fairly referred to loss of blood. This opinion may, however, be materially modified by the fact of the body not being seen on the spot where the fatal wound was actually inflicted,—by the wound having been sponged,—the blood removed by washing, and all traces of bleeding destroyed. Under these circumstances, the case must in a great measure be made out by presumptive proof: and here a medical witness may have an important duty thrown upon him, namely, that of examining articles of dress, furniture, or weapons for marks or stains of blood. (See ante, p. 378, 281.)

It must not be supposed that all the blood met with round a wounded dead body, was actually effused during life. As soon as the heart's action ceases, the arteries pour out no more; but the blood, so long as it remains liquid, i. e. from four to eight or ten hours, and the warmth of the body is retained, continues to drain from the divided veins and smaller vessels. The quantity thus lost, however, is not very considerable, unless the veins implicated be large. A question relative to the degree of this bleeding after death has very frequently been put in a Court of law.

II. Death from great mechanical injury done to a vital organ.—We have instances of this becoming a direct cause of death in the crushing of the heart, lungs, or brain, by any heavy body passing over or falling on the cavities, as in railway accidents. The severe mechanical injury is sometimes accompanied by a considerable effusion of blood, so that the person really dies from haemorrhage; but in other instances the quantity of blood lost is inconsiderable and the fatal effects may be referred to shock.

III. Death from shock.—This is sometimes a direct cause of death under the infliction of external violence; and in this case life is destroyed without the injury being to all appearance sufficient to account for so speedily fatal a result. There is no medical doubt that a person may die from what is termed shock without any marks of severe injury being discovered on the body after death. We have examples of this mode of death in accidents from lightning, or from severe burns or scalds, in which the local injury is often far from sufficient to explain the rapidly fatal consequences. As instances of this form of death from violence, may be also cited those cases in which a person has been suddenly
killed by a blow upon the upper part of the abdomen or on the pit of the stomach, which is supposed to operate by producing a fatal impression on the cardiac plexus. Whether this be or be not the true explanation, the fact itself is undisputed; it is certain that a person may die from so simple a cause without any appearance being produced externally or internally to account for death. On the skin, there may be some marks of abrasion or slight discoloration; but, as it has been elsewhere stated, these are neither constant nor necessary accompaniments of a blow. (An account of the appearances observed in a case of this kind, by Mr. Wood, will be found in the Medical Gazette, vol. xlv. p. 213.) Convictions for manslaughter have taken place, when death has been produced under these circumstances. Concussion of the brain, unattended by mechanical lesion, is another example of this kind of death. A man receives a severe blow on the head; he falls dead on the spot, or becomes senseless and dies in a few hours. On an inspection, there may be merely the mark of a bruise on the scalp; in the brain there may be no rupture of vessels or laceration of structure, and all the organs of the body are found healthy. In certain railway accidents persons have died under somewhat similar circumstances. There may be no physical indication of a mortal injury; and no cause apparent to account for death. This can only be referred to the shock or violent impression which the nervous system has sustained from the blow,—an impression which the vital powers were wholly unable to counteract or resist. A medical witness must give his evidence with caution in such cases; since it is the custom to rely in the defence upon the absence of any visible mortal wound or physical injury to account for death,—a principle which, if once unrestrictedly admitted as correct, would leave a large number of deaths, undoubtedly occurring from violence, wholly unexplained. A trial took place at the Liverpool Autumn Assizes, 1837, wherein several persons were charged with the manslaughter of the deceased, by kicking him behind the right ear. The medical witness deposed that there was in this spot the mark of a severe contusion, but there was no injury whatever to the brain, and the body was otherwise healthy. He very properly ascribed death to the violent shock given to the nervous system, and the Court admitted that the cause of death was satisfactorily made out. The party who inflicted the wound was convicted.

There is another form of shock, which is of some importance in medical jurisprudence. A person may have received many injuries, as by blows or stripes, not one of which, taken alone, could, in medical language, be termed mortal; and yet he may die directly from the effects of the violence, either on the spot, or very soon afterwards. Death is commonly referred to exhaustion, but this is only another mode of expression; the
exhaustion is itself dependent on a fatal influence or impression produced on the nervous system. A prizefighter, after having, during many rounds, sustained numerous blows on the body, may, either at or after the fight, sink and die exhausted. His body may present marks of bruises, or even lacerated wounds, but there may be no internal changes to account for death. In common language, there is not a single injury which can be termed mortal; and yet, supposing him to have had good health previously to the fight, and all marks of disease indicative of sudden death to be absent, it is impossible to do otherwise than refer his death to the direct effect of the violence. A case of a somewhat similar kind may present itself in the military punishment of flagellation, which is occasionally followed by death, either as a direct consequence of shock, or from indirect causes, such as inflammation and its consequences. In a case which occurred at Hounslow (July, 1846), it was considered that the inflammation of the heart and pleura, of which the man had died, had arisen from the disorganised condition of the back, produced by flogging.

It is a well-ascertained medical fact, that a number of injuries, each comparatively slight, are as capable of operating fatally, as any single wound whereby some blood-vessel or organ important to life is directly affected. Age, sex, constitution, and the previous state of health or disease, may accelerate or retard the fatal consequences. In the case of Governor Wall, the judge directed the jury that the long continuance and severity of pain (in flagellation) may be productive of as fatal consequences as if instruments or weapons of a destructive kind were used. On a trial for murder, which took place in Germany a few years since, it was proved that the deceased had been attacked with sticks, and that he had been afterwards flogged on the back with willow switches. He died in about an hour. On inspection, there was no mortal wound, nor any injury to a vital organ; there were simply the marks of lacerations and bruises on the skin, apparently not sufficient to account for death; but this was nevertheless very properly ascribed to the violence. (Henke, Zeitschrift der S. A. 1836.) The case of the Duchess of Praslin, who was murdered by her husband in Paris, in August 1847, furnishes an additional proof of the fatal effects produced by numerous injuries. On an inspection of the body, it was found that on the head, neck, and both of the hands, there were no fewer than thirty distinct wounds, some contused, and others incised and punctured. There were also the marks of many bruises, and the impressions produced by the nails of the murderer's hand over the mouth. For the most part, these injuries were slight, and not one could be said to be necessarily mortal. The most serious wound was situated on the right side of the neck; but even here the carotid artery and internal jugular vein had
escaped injury. Death was referred to the loss of blood which had taken place from the numerous wounds inflicted during the struggle with the assassin. (Ann. d’Hyg. 1847, ii. 377.) From these considerations, it is obviously absurd to expect that in every case of death from violence or maltreatment, there must be some specific and well-defined mortal lesion to account for that event. When the circumstances accompanying death are unknown, a medical opinion should certainly be expressed with caution; but if we are informed that the deceased was in ordinary health and vigour previous to the infliction of the violence, and there is no morbid cause to account for his sudden illness and death, there is no reason why we should hesitate in referring death to the effects of a number of injuries. Among non-professional persons, an unfounded prejudice exists that no person can die from violence unless there be some distinct mortal injury actually inflicted on the body. By this we are to understand a visible mechanical injury to some organ or blood-vessel important to life; but this is obviously a very erroneous notion, since death may take place from the disturbance of the functions of an organ without this being necessarily accompanied by a perceptible alteration of structure. The prevalence of this popular error often leads to a severe cross-examination of medical witnesses. Among the questions put, we sometimes find the following:—Would you have said, from the wounds or bruises alone, that they were likely to have occasioned death? Now, in answer to this, it may be observed, that we cannot always judge of the probability of death ensuing from the appearance of external violence alone. Because the appearances were slight, it would be wrong to infer in any case that they were not sufficient to cause death. A man may die from a blow on the pit of the stomach, and how can this fact be determined by an examination of the body? Then it may be inquired, Were the wounds or bruises mortal? In the vulgar sense of the word, i.e., by producing great loss of blood or a destruction of parts, they might not be so; but in a medical view, they may have acted mortally by producing a shock to the nervous system. Again it may be inquired, which of the several wounds or bruises found on the body of the deceased was mortal? The answer to this question may be,—Not one individually, but all contributed to occasion death by exhaustion.

It must likewise be remembered, that in cases in which a person has sustained a number of injuries, the loss of a much smaller quantity of blood than in other instances, will suffice to destroy life. It is sometimes a very difficult question to decide on the relative degree of mortality of wounds, and on the share which they have had respectively in causing death. By a wound being of itself mortal, we are to understand that it is capable of causing death directly or indirectly, in spite of the best medical
assistance. It is presumed that the body is healthy, and that no cause has intervened to bring about or even accelerate a fatal result. The circumstance of a person labouring under disease when wounded in a vital part, will not, of course, throw any doubt upon the fact of such a wound being necessarily mortal, and of its having caused death. If there should be more wounds than one, it is easy to say, from the nature of the parts involved, which was likely to have led to a fatal result. In order to determine, on medical grounds, whether a wound was or was not mortal, we may propose to ourselves this question: Would the deceased have been likely to die at the same time, and under the same circumstances, had he not received the wound? There can obviously be no general rule for determining the mortal nature of wounds. Each case must be judged by the circumstances which attend it. In some continental states, the law requires that a medical witness should draw a distinction between a wound which is absolutely and one which is conditionally mortal. An absolutely mortal wound is defined to be that in which the best medical assistance being at hand, being sent for, or actually rendered, the fatal event could not be averted. Wounds of the heart, aorta, and internal carotid arteries, are of this nature. A conditionally mortal wound is one in which, had medical assistance been at hand, been sent for, or timely rendered, the patient would, in all probability, have recovered. Wounds of the brachial, radial, and ulnar arteries may be taken as instances. The responsibility of the assailant is made to vary according to the class of injuries to which the wound may be referred by the medical witnesses; and, as it is easy to suppose, there is seldom any agreement on the subject. Our criminal law is entirely free from such subtleties. The effect of the wound, and the intent with which it was inflicted, are looked to: its anatomical relations, which must depend on pure accident, are never interpreted in the prisoner's favour. Some extenuation might, perhaps, be occasionally admitted when a wound proves mortal through an indirect cause, as inflammation or fever, and medical advice was obtainable, but not obtained until every hope of recovery had disappeared. It would appear, however, from the case of the Queen v. Thomas and others (Gloucester Ass. 1841), that the mere neglect to call in medical assistance is not allowed in law to be a mitigatory circumstance in the event of death ensuing. The deceased died from the effects of a severe injury to the head inflicted by the prisoners, but had had no medical assistance. The judge said it was possible that, "if he had had medical advice, he might not have died: but whoever did a wrongful act must take the whole consequences of it. It never could make any difference whether the party injured had or had not the means or the mind to apply for medical advice." The prisoners were convicted. According to Lord Hale, if a man be
wounded, and the wound, although not in itself mortal, turn to a gangrene or fever for want of proper applications, or from neglect, and the man die of gangrene or fever, this is homicide in the aggressor; for though the fever or gangrene be the immediate cause of death, yet the wound being the cause of the gangrene or fever, is held the cause of death, causa causati. These nice questions relative to the shades of responsibility for personal injuries, occasionally arise in cases in which individuals have been wounded at sea on board of a ship in which there was no surgeon.

CHAPTER XXVII.

Examination of blood-stains. — It might appear at first sight a very easy matter to say whether certain suspected spots or stains on articles of clothing, furniture, or weapons, were or were not due to blood; but, in practice, great difficulty is often experienced in answering the question. If the stains be large and recent, most persons may be competent to form an opinion; but the physical characters of blood are soon changed, even when the stuff is white and otherwise favourable to an examination. Again, when the stains, whether recent or of old standing, are upon dark-dyed woollen stuffs, as blue, black, or brown cloth, or when they appear in the form of small or detached spots or thin films on dark clothing or rusty weapons, no one but a competent medical man should be allowed to give an opinion. It is, however, by no means unusual to find questions put to policemen respecting the nature of suspected stains! — a practice obviously unjust to the accused, and fraught with considerable danger.

Chemical analysis.—There is no direct chemical process by which blood can be identified, but we presumptively establish its nature by determining the presence and properties of the red colouring matter, or haematoine. The microscope may be most
usefully employed in these medico-legal investigations, either alone, or in those cases in which chemistry fails to aid the practitioner. The chemical properties of the red colouring matter of blood are as follows: 1. The colouring matter of blood readily combines with cold distilled water, forming, if recent, a rich red solution. 2. The red colour of this solution is not changed to a crimson or a green tint by a few drops of a weak solution of ammonia: if the ammonia be very concentrated, or added in large quantity, the red liquid acquires a brownish tint. 3. The red liquid when boiled is coagulated — the colour is entirely destroyed, and a muddy brown flocculent precipitate is formed,—the quantity of which will depend on the quantity of colouring matter and albumen present. 4. The coagulum produced by boiling, when collected on a filter and dried, forms a black resinous-looking mass, quite insoluble in water, but readily dissolved by boiling caustic potash, forming a green-coloured solution. 5. To the above tests some have united the action of strong nitric acid, which coagulates the red colouring matter, turning it of a dirty brown hue. Such are the chemical properties of blood, whether derived from the body of man, or from any warm red-blooded animal.

M. Bouthigny has suggested the application of these tests, by taking advantage of the spheroidal state of liquids on red-hot metals. (Ann. d’Hyg. 1844, ii. 217.)

Objections to the tests.—It will now be proper to mention the action of the tests upon red colouring matters, extracted from the animal or vegetable kingdom. Some of these are changed to a green colour by ammonia, as the colouring matter of the rose,—others to a crimson, as the red colouring matters of cochineal, logwood, and lac. None of these red colours are coagulated or destroyed by boiling. In these respects, therefore, the colouring matter of the blood is eminently distinguished from them. M. Raspail has objected that a mixture of madder and albumen possesses all the characters assigned to blood. Having for some years past performed numerous experiments on this subject, by making artificial mixtures of human serum or animal albumen, with the red colouring matters of cochineal, lac, and madder, and neutralising the effects of the alkali contained in the serum by the addition of a small quantity of acetic acid, I can state that in no respect whatever, except in regard to colour, can such mixtures be confounded with blood. The objection is, therefore, more theoretical than practical. These red liquids may easily deceive those who trust to a red colour alone; and herein we see the absolute necessity for placing the investigation of such subjects in the hands of professional persons only. It may be observed of all such artificial mixtures, that they are changed by ammonia to a crimson or a green tint (sometimes passing through a blue), and that under no circumstances is the
coagulated and destroyed like the red colour. (Guy’s Hosp. Reports, October 1851.) It was by some chemists, that the blood owed its colour of _sulphocyanate of iron_. When this mineral comes in contact with albumen or serum in water, in a certain period of time it assumes a resemblance to a solution of the colouring matter. The action is very great, that, from appearance only, it would be impossible to distinguish them. The effects of the application of this solution upon a strip of paper are widely different. A coagulum is formed in the same way, the solution of the sulphocyanate of iron, and the red colour of the blood is immediately destroyed by ammonia, is not destroyed by boiling.

_Stains of blood on linen and other stuffs._—Suppose the stain to be white or nearly colourless, the spot of blood after a period of five or six days takes on a deep red colour; but it becomes of a reddish brown, by keeping. The change of colour takes place in warm weather in from one to four hours. After a period of five or six days it is impossible to determine the date of a stain even by careful observation. In a large stain of blood on linen, no change takes place; a new stain of five years:—it had a brown colour after a few weeks, which it retained for the long period mentioned. It is extremely difficult in any case, after the lapse of time, to give an opinion as to the _actual date_ of a stain.

In the case of stains of blood,—on red-dyed stuffs the stain is simply darker from the first, and in all cases the colour is more or less stiffened. Attention should be paid to the texture of the stuff, if an article of dress, e.g., a handkerchief, is used.
readily pervious to water. When the stain is on thin silk it is speedily separated. Several slips of the stuff may be thus successively treated, until a liquid, sufficiently deep in colour for testing, is procured. If the quantity of coloured liquid thus obtained be small, the supernatant clear water may be carefully poured off, or drawn off by a pipette; but it is better to use a small tube and a small quantity of water. The coloured liquid may then be tested by weak ammonia, and by the application of heat. If ammonia produce any effect upon the solution of blood, it is simply to brighten it,—this alkali never changes the red colour of blood to green or crimson. When the stain is of old standing, the solution in water is more slowly obtained, and does not present the bright red colour of blood. The action of ammonia may also be obscure, although it never gives to the liquid a green or crimson tint. The action of heat is in such cases certain and effectual: if the coloured solution be in such small quantity that there is no coagulum obtained by heat, it is impossible to give a decided opinion, from the application of chemical tests, that the stain is due to blood. In May 1838, a piece of linen was examined in which there were two faint spots of blood, each about a quarter of an inch in diameter. A reddish-coloured liquid was procured, but no coagulum could be obtained on boiling. In these ambiguous cases it will be necessary to resort to the use of the microscope. When the quantity of blood effused is moderately large, it may be easily detected by the above process, even after the lapse of a great length of time. I have thus detected the blood of the human subject, and of the bullock, on cotton, linen, and flannel, after the lapse of three years. If the stuff be dyed, we should proceed to examine the stains found upon it by a similar process. The dye is commonly fixed, and is not soluble in water. If the colour should be soluble, and form an obstacle, the microscope must be resorted to. Thus, then, in testing for blood, we rely upon—1, the ready solubility of the haematosine (or red colouring matter) in water; 2, the negative action of ammonia; and 3, the positive effect of heat in entirely coagulating and destroying the red colouring matter.

Objections.—It may, however, be objected, that red stains closely resembling blood are occasionally found on linen and other stuffs. It is to be remarked of all such stains, that they are either entirely insoluble in cold water, or they are soluble. If insoluble, they cannot by any possibility be mistaken for blood. It is very true, that if the linen or stuff which is stained with blood be heated to a high temperature, the colouring matter may, by its having become coagulated, be rendered insoluble in water:—but it is not probable that medical evidence will be thus defeated, except by those who have made a profound study of the difficulties of medical jurisprudence. In the case of a body
found wounded and burnt, it would be proper to allow for such a change, and the chemical evidence would fail. If the blood-stain be mixed with oil or grease, this will interfere with the action of water. If the stain be on a plaster-wall or on wood, we must scrape or cut out a portion, and digest it in a small quantity of water in a tube or watch-glass. It will be proper here to examine well, in the first instance, an unstained portion of the plaster or wood.

Detection of fibrin. — In this process for examining blood-stains, it has not been thought necessary to refer to the properties of fibrin. Fibrin forms about 1/500th part of human blood: it exists in the blood of all warm-blooded animals: the other animal liquida in which it is found are the chyle and lymph. It is the chief constituent of muscular fibre. When the blood is in sufficient quantity, a pale film of fibrin may be left upon the stained substance, after the colouring matter has been removed by digestion in water. Small quantities of fibrin are not easily identified by its chemical properties. Animal fibrin so closely resembles coagulated albumen and gluten, that it cannot be distinguished from them by chemical tests. Hence, unless evidence of the presence of red colouring matter be obtained, the presence of fibrin cannot be relied on; and if this evidence be obtained, the demonstration of its properties is unnecessary: for there is no red colouring matter which, under due precautions, can be mistaken for that of blood. Evidence on this subject was tendered in the case of Reg. v. Reed (York Winter Assizes, 1847), but it was not well received by the Court. It has been supposed that the demonstration of the presence of fibrin in a blood-stain would enable us to say whether the blood had been effused from a living or dead body; but, admitting that the existence of fibrin in a small quantity of dried blood upon an article of dress could be indisputably established, the fact would not enable us to give a conclusive answer to the important question above suggested. If the quantity of blood examined be comparatively great, and no fibrin can be procured from it after complete digestion in cold water, it is probable that this blood has not come from a living body, and that it is merely a mixture of red colouring matter and serum, like that found in the vessels of the dead body after perfect coagulation. But the experimentalist must bear in mind that small stains of blood will commonly leave no perceptible traces of fibrin. On the other hand, if fibrin were clearly obtained, it would be by no means proved that the blood yielding it had issued from a living body. Until the blood has coagulated, it retains fibrin: and coagulation seldom commences in the dead body until after the lapse of four hours; although, if drawn, it speedily consolidates, i.e. within a few minutes. Hence the dress of a person sprinkled with blood from a recently dead body would yield all the characters of stains
which had been produced by the effusion of blood from a wound inflicted on the living body. (See, on the subject of blood-stains, Ann. d’Hyg. 1829, pp. 267, 548 ; 1830, p. 433 ; 1831, p. 467 ; 1833, p. 226 ; 1834, p. 205 ; 1835, ii. p. 349 ; 1839, i. p. 219 ; 1840, i. p. 387 ; also, Henke’s Zeitschrift der S. A. 1844, ii. p. 273. See also, for a full account of this subject, Guy’s Hosp. Reports, Oct. 1851.)

Insoluble stains.—Among what may be classed as insoluble stains, are — 1, certain red dyes, as madder, which, when fixed by a mordant, is not readily affected by ammonia. 2. Iron-moulds. These are of a reddish-brown colour, sometimes of a bright red, — they are quite insoluble in water, but are easily dissolved by diluted muriatic acid, and on adding ferrocyanide of potassium to the muriatic solution, the presence of iron will be at once apparent. Care should be taken that the muriatic acid used for this purpose contains no iron. The stained article of dress should also be proved to be free from any iron-dye, or a blood-stain might be erroneously pronounced to be due to iron. Some years since, a man was found drowned in the Seine, at Paris, under suspicious circumstances. The body had evidently lain a long time in the water. On examining the shirt of the deceased, a number of red-brown stains were observed on the collar and body, — resulting, as it was supposed, from spots of blood, which had become changed by time. On a chemical examination, however, they were found to be iron-moulds produced by the corrosion of a steel-chain which the deceased had worn round his neck! 3. Red paint. Stains made with red paint have been mistaken for blood. In March 1840, a person was murdered at Ilmington. An individual was arrested on suspicion, and in his possession was found a sack, having upon it many red stains, which were supposed to be dried and coagulated blood. They were examined by Professor Graham, who found that they had been caused by red paint, containing peroxide of iron; and the sack was proved to have been worn as an apron by a youth who was an apprentice to a paper-stainer. It had been sent to the accused party a few days before, as a wrapper to a parcel. The accused was immediately discharged. Stains of this kind may be easily known by digesting them in diluted muriatic acid, and applying to the solution the tests for iron. Like those produced by iron-moulds, they are perfectly insoluble in water, and therefore cannot be confounded with blood-stains. The same may be said of spots of the ammonio-nitrate of silver changed by light, which I have known to be mistaken for old stains of blood. The stuff on which the spots of blood are found, may be itself stained with a red dye or colour, or it may be dyed with iron: in this case it will be necessary to test by the same process a piece of the coloured or stained portion, in order to furnish negative evidence that the suspected stains are due to blood. In Spicer’s case
STAINS ON CLOTHING RESEMBLING BLOOD.

(ante, pp. 271, 272), an apron which the prisoner wore was found with stains of blood upon it: but the greater part was covered with dark-red stains, which turned out to be owing to a logwood-dye that the prisoner had used in his business. (Med. Gaz. xxxvii. 613.)

Soluble stains.—Among the soluble stains resembling those of blood, are the spots produced by the juices of the mulberry, currant, and other red fruits. These are commonly recognised by dropping on them a weak solution of ammonia, when the spot is turned either of a bluish, olive-green, or green colour. The red of cochineal is changed to a crimson on the addition of ammonia or potash. A spot of blood thus treated undergoes no change from the alkali. Further, if a piece of the stained stuff be suspended in water, the coloured liquid, if any be obtained, is easily known from blood, by its acquiring a green or crimson tint on the addition of ammonia, and by the red colour not being coagulated or destroyed when the liquid is boiled. Independently of the fruits mentioned, there are many vegetable juices that will produce stains of a red or red-brown colour, which might be mistaken for blood. In the following case, the red petals of the poppy gave rise to an error only removed by a proper examination. A farmer's lad was arrested upon a charge of murder. The blue blouse and trousers which he wore, had on them numerous brown and red stains resembling blood, and apparently produced by the wiping of bloody fingers. The stained articles were subjected to a chemical examination, and it was found that the colour was caused by some vegetable juice. The accused, when interrogated on the subject, stated, that the day before his arrest, he had collected a large quantity of red poppies, which had become bruised by his trampling on them, and that he had carried them in his blouse. The apparently suspicious circumstance was thus explained away. (Bayard, Man. Prat. de Méd. Lég. 217.) The petals of various plants, according to this writer, produce stains which might be mistaken for blood.

In some red stuffs, the dye is often so bad, that water will dissolve out a portion of the colour; but in this case the action of ammonia and heat will serve readily to distinguish the stains from blood. If minute spots be scattered on articles of furniture, these may be examined by cutting out the stained portions, and treating them by the process mentioned. It is said that blood-stains, when minute and scattered, are more readily recognised and identified by the light of a candle than in the light of day. Much reliance cannot be placed on this statement. The brown stains of blood appear to acquire a redder tint.

The soluble red or brown stains given by woods or roots, such as Logwood, Brazil-wood, or Madder-root, are changed to a crimson colour by ammonia. They also generally contain tannic
acid, and acquire a dark olive green colour when a persalt of iron is added to the liquid. Red-brown extracts, such as Kino and Catechu, are not affected by ammonia; but the colour given to water is different from that of blood, and the addition of a persalt of iron reveals the presence of tannic acid. [For a further account of the differences between red dyes and blood, see Guy’s Hospital Reports, October 1851.]

Removal of blood-stains.—An attempt may have been made to wash out blood-stains, so that the colour may be more or less changed, and no chemical evidence obtained. There is a common notion that certain chemical agents will remove or destroy these stains; but this is not the case,—the colour may be altered, but when dried on the stuff it is not easily discharged or bleached. Chlorine, a most powerful decolorizing agent, turns the colouring matter of blood of a green-brown colour. Hypochlorous acid has a similar effect. This acid has been recommended as useful by its bleaching properties for distinguishing the stain of blood from all other stains, excepting those produced by iron-rust. Orfila has, however, shown that it is not fitted for such a purpose, and that there are no better methods of testing, than those above described. (Ann. d’Hyg. 1845, ii. 112.) I have found that nothing removes a blood-stain, whether wet or dry, so effectually as simple maceration in cold water, although, when the stain is old, the process is sometimes slow. On a trial for murder, at the Shewsbury Lent Assizes, 1841 (the Queen against Misters), a question arose on the efficacy of certain re-agents in discharging stains of blood. Alum was traced to the possession of the prisoner; it was found dissolved in a vessel in his bed-room, and it was supposed that he had removed some blood-stains from his shirt by the use of this salt. Two medical witnesses deposed that they had made experiments, and had found that alum would take the stains of blood out of linen:—according to one, sooner than soap and water. The results of my experiments do not correspond with these. I have not found that alum extracts stains of blood when dried on stuffs so readily as cold water, and when alum is added to a solution of the red colouring matter of blood in water, so far from the colour being discharged, it is slowly converted to a deep greenish-brown liquid. In one experiment, a slip of linen, having upon it a deep stain of dried blood of old standing, was left in a strong solution of alum for twenty-four hours; but not a particle of the red colouring matter had been extracted, although it was changed in colour. The prisoner’s guilt did not rest on this point alone,—that was made sufficiently evident from other circumstances: but there have been few cases tried in England in which the facts connected with the analysis of blood-stains were so closely examined or were of such great importance, as in this. In a case to be presently related, I was consulted on the question whether the alkali con-
tained in yellow soap would alter or remove blood-stains. The effect of this substance, as well as of the carbonates of potash and soda and many other reagents, is to change the red colour of blood to a deep-greenish brown,—but they do not exert on it any discharging or bleaching power. Combined with friction, blood-stains, especially when in the wet state, may be easily and entirely effaced by any cold alkaline or soapy liquid.

Detection of blood on weapons.—When recent, and on a polished instrument, stains of blood are easily recognised; but when of old standing, or on a rusty piece of metal, it is a matter of some difficulty to distinguish them from the stains produced by rust or other causes. If the stain of blood be large, a portion will readily peel off on drying. This may be placed in a watch-glass of distilled water, filtered to separate any oxide of iron, and then tested. If the water by simple maceration do not acquire a red or red-brown colour, the stain is not due to blood. Sometimes the stain appears on a dagger or knife either in the form of a thin yellowish or reddish film, or in streaks, and is so superficial that it cannot be mechanically detached. We should then pour a stratum of water on a piece of plate-glass, and lay the stained part of the weapon upon the surface. The water slowly dissolves any portion of the colouring matter of blood, and this may be examined by the process recommended. If the weapon have been exposed to heat, this mode of testing will fail.

Objections.—There is often a remarkable resemblance to the stains of blood on metal, produced by the oxide or certain vegetable salts of iron. If the juice or pulp of lemon or orange be spread upon a steel-blade, and remain exposed to air for a few days, the resemblance to blood produced by the formation of citrate of iron is occasionally so strong that I have known well-informed surgeons to be completely deceived:—they have pronounced the spurious stain to be blood, while the real blood-stain on a similar weapon was pronounced to be artificial. The difficulty of distinguishing such stains by the eye, is well illustrated by a case which occurred in Paris a few years since. A man was accused of having murdered his uncle, to whose property he was heir. A knife was found in his possession, having upon it dark-coloured stains, pronounced by those who saw them to be stains of blood. M. Barruel, and another medical jurist, were required to determine the nature of the stains, and the examination was made before a magistrate in the presence of the accused. They were clearly proved, by these and other experiments, to be spots produced by the citrate of iron. It appeared on inquiry, that the knife had been used by some person a short time previously, for the purpose of cutting a lemon; and not having been wiped before it was put aside, a simple chemical action had gone on between the acid and the metal, which had given rise to the appearance. This case certainly shows that physical characters
MISTAKES REGARDING BLOOD-STAINS.

alone cannot be trusted in the examination of these suspected stains. Stains of the citrate of iron may be thus known. The substance is soluble in water, forming, when filtered, a yellowish-brown solution, totally different from the red colour of blood under the same circumstances. The solution undergoes no change of colour on the addition of ammonia. It is unchanged in colour, but may be partially coagulated at a boiling temperature: and it is at once identified as a salt of iron, by giving a blue colour with the ferrocyanide, and a deep red with sulphocyanide of potassium. I have also observed, that spots of the citrate of iron on knives, for they are not found on other weapons, are often soft and deliquescent, while those of blood are commonly dry and brittle.

It might be supposed to be a very simple matter to distinguish by sight a stain of blood on a weapon from a mark produced by iron-rust: but this is not the case. When suspicion exists, it is astonishing how readily mistakes are made; and marks are pronounced to be due to blood, which, under other circumstances, would have passed unnoticed. One source of difficulty is this: the iron-rust is often mixed with articles of food on an old knife, or even with blood itself. We must here pursue the same mode of examination as if the stain were of blood; we macerate the weapon or a portion of the coloured deposit in a small quantity of distilled water, and filter the liquid. If the stain be due to iron-rust this is separated by filtration, and the liquid passes through colourless. The absence of blood is thereby demonstrated: for I need not here consider the objection, that the weapon may have been exposed to heat, and thus have rendered the blood-stains insoluble in water. If we now digest the brown undissolved residue left on the filter, in diluted muriatic acid free from iron, we shall obtain a yellowish solution, which will give with the ferrocyanide and sulphocyanide of potassium the proper reactions for iron. It has been recommended to put muriatic acid on the stain as it exists on the weapon, and then to test the liquid, as the red spot of rust is soon removed by the acid; but the objection to this is, that a spot containing blood may be thereby pronounced to be one of rust only, since muriatic acid, in all cases, dissolves a portion of the iron, and the solution would therefore give the characters of an iron-stain with the tests. In all old blood-stains, when the weapon is rusty, blood and oxide of iron are intermixed. The blood may be easily separated by digesting the compound in distilled water, and filtering: the colouring matter is dissolved, and passes through, while the rust is left on the filter.

The following case was referred to me for examination a few years since. A man was suspected of murder, and some stains existed on his shirt, which were supposed to have been produced by blood. Around the collar and upper part of the shirt, there
was a large and somewhat deep pinkish-red stain, in some respects resembling washed blood. This I considered as a very unusual situation for blood to be found sprinkled; and upon trying the stained linen by the processes mentioned, the colour entirely resisted separation by water, and was turned of a slight crimson tint by ammonia. The stain was thus shown not to be due to blood. On inquiry, it was ascertained that the man had worn round his neck a common red handkerchief during a wet night, and while taking violent exercise! The stain was thus accounted for. There were, however, some other marks on the shirt which required examination, as there was a very strong suspicion against this man. These were on the sleeves, at those parts which would be likely to receive stains of blood, if they had been rolled or turned up at the wrists; and it was clearly ascertained, that the murderer, in this case, used a quantity of yellow soap in washing his hands. These stains were of a brownish colour, without any shade of red; they were faint in parts and diffused, conveying the impression that an attempt had been made to wash them out. So far as external characters were concerned, it was difficult to say whether they had been produced by blood or not. On examining the parts of the shirt corresponding to the armpits, stains precisely similar were there seen, evidently resulting from cutaneous perspiration; since the suspicion of blood being diffused on these parts of the shirt under the circumstances, could not be entertained. Slips of linen from the stained portions of the sleeves were digested in water. In twenty-four hours the stains were entirely removed; and the lower stratum of water in each tube had acquired a straw-yellow colour. There was not the least shade of a red or brown tint; and the solution was wholly unlike that produced by blood under any circumstances. The solution was unaffected by ammonia, as well as by a heat of 212°; but it acquired a faint opalescence on the addition of nitric acid. These results not only indicated the absence of blood, but showed that the stains were due to cutaneous perspiration issuing from a dirty skin, and through a dirty dress. The stains on the parts corresponding to the armpits could not be ascribed to blood; and from the similarity in physical and chemical properties, it was impossible to attribute those on the sleeves to any sanguineous effusion. It happened, however, that a large pocket-knife, with numerous dark red stains on the blade and between the layers of the handle, was found upon this man; and this was also sent for examination. Several persons who saw the knife pronounced a strong opinion that the marks were due to blood. The stains were composed of some soft viscid matter, which gave out ammonia when heated, and left a residue of peroxide of iron. On digesting the matter in water no portion was dissolved; and it was, therefore, evident that they were due not to blood, but to a mixture of some animal
matter, probably food, with iron-rust. These results were some-
what in the man's favour,—at least, they removed what was
considered to be a strong circumstantial proof of his guilt. He
was subsequently tried for the murder, and acquitted on an alibi,
established by the evidence for the prosecution.

Conclusions.—From the foregoing remarks, we may justly
infer that a chemical analysis of suspected spots or stains on
weapons and clothing, is by no means a trivial or unimportant
duty. If we cannot always obtain from these experiments
affirmative evidence, they often furnish good negative proof, and
thus tend to remove unjust suspicions against accused parties.
There is one circumstance, however, of which a medical jurist is
entitled to complain, namely, that evidence should be received on
matters of this kind from non-professional persons, or that any
confidence should be placed in an opinion derived from physical
characters only. On the occasion of the murder of Eliza Grim-
wood, in June 1838, committed, as it was, under circumstances
of the greatest mystery, and the perpetrator of which has not yet
been discovered, the examination of suspected marks resembling
blood became rather an important part of the inquiry: but it was
most improperly conducted. The finger plates of the door of
the room, in which the murder was perpetrated, presented some
dark stains, supposed to have been produced by the bloody hand
of the murderer in the act of escaping. The only test to which
these were submitted was, that the magistrate before whom the
case was heard, tried to rub off some of the stains with a piece
of blotting-paper, but did not succeed; and he expressed his
opinion, that if they were blood-stains they had been wiped!
It is easy to perceive to what evil results superficial examinations
of this kind may lead.

Varieties of blood.—The means of distinguishing arterial from
venous blood, available to the medical jurist, have been elsewhere
described (see ante, p. 285). There is no method known by
which the blood of a man can be distinguished from that of a
woman, or the blood of a child from that of an adult. The
blood of a child at birth contains less fibrin, and forms a
thinner and softer coagulum than that of the adult. The
medico-legal question has arisen on more than one occasion,
whether there were any means of distinguishing menstrual blood
from that of the body generally. This liquid contains fibrin,
although the proportion is much less than in venous or arterial
blood, red colouring matter, and the other constituents of blood.
The only differences noticed are of an accidental kind:—
1st., that it is acid, owing to its admixture with vaginal mucus;
and 2nd., that under the microscope it is mixed up with epil-
thelial scales, which it has derived from the mucous membrane
in its passage through the vagina. (Donné, Course de Micro-
scopic, p. 139.) A case occurred in France, which induced the
Minister of Justice to refer the consideration of this question to the Academy of Medicine. The reporters, MM. Adelon, Moreau, and Le Canu, came to the conclusion, that there were no means of distinguishing menstrual blood dried on clothing from that which might be met with in a case of infanticide or abortion. (Ann. d'Hyg. 1846, i. 181.)

**Blood of man and animals. — Tests by odour.** — When marks of blood have been detected on the dress of an accused person, it is by no means unusual to find these marks referred to his having been engaged in killing a pig or a sheep, or handling fish or dead game. Of course every allowance must be made for a statement like this, which can only be proved or disproved by circumstances; but an important question here arises, namely, whether we possess any certain means of distinguishing the blood of a human being from that of an animal. M. Barruel, and other French medical jurists, state that by mixing fresh blood with one-third or one-half of its bulk of strong sulphuric acid, and agitating the mixture with a glass rod, a peculiar odour is evolved, which differs in the blood of man and animals, and also in the blood of the sexes. This odour, it is said, resembles that of the cutaneous exhalation of the animal the blood of which was made the subject of experiment. They have hereby pretended to determine, whether any given specimen of blood belonged to a man, a woman, a horse, sheep, or fish. Others assert that they have been enabled by this process to identify the blood of frogs and fleas! (See Devergie, Méd. Lég. ii. 907.) It is true that an excess of strong sulphuric acid does give rise to a particular odour when mixed with fresh blood, probably owing to its decomposing some of the animal principles; it is possible that some persons may discover a difference in the odour, if not according to the sex, at least according to the animal, —but even this point is far from being established: and if it were admitted, there is probably not one individual among a thousand, whose sense of smelling would be so acute as to allow him to state with undeniable certainty, from what animal the unknown blood had really been taken. Any evidence short of this would not be received in an English Court of law; for it is considered better not to decide at all, than to decide on principles which are exposed to unavoidable fallacy. Besides, it must be remembered, that in general the operator has not before him the fresh blood, but merely a diluted solution of the dried colouring matter mixed with a small quantity of serum. In a case of some importance which lately occurred in Paris, the testing of blood by odour completely failed in the hands of M. Barruel and two other eminent French medical jurists, MM. Tardieu and Chevallier. The mistakes made by these experts are admitted by themselves to have been of so serious a nature as to render
this mode of obtaining evidence in any future case inadmissible. (Annales d’Htg. 1853, i. 413.) For additional remarks on this subject, see paper in Guy’s Hospital Reports, Oct. 1851.)

M. Taddei, of Florence, has suggested another process for distinguishing human from animal blood, and the varieties of animal blood from each other. He calls his method hæmatalloscopy (άιμα αλλιων σκοπειν). It is a process of the most complex kind, and essentially depends on the supposed varying degrees of fluidifiability of blood in different animals. By the addition of an artificially prepared compound, mixed with sulphuric acid, he alleges that he has been able to distinguish human from animal blood, and to fix measurable degrees of fluidifiability so as to allow an opinion to be expressed! Even if the complexity of the process were not a sufficient objection to its employment, the results, as the author describes them, are so vague and unsatisfactory as to render it wholly inapplicable to practical purposes. An account of the process will be found in Briand’s Manuel Complet de Médecine Légale, 1846, p. 745.

Microscopical evidence.—The microscope has been of late years employed not only to distinguish blood from other coloured liquids, but for drawing a distinction between the blood of different classes of animals. The red colouring matter of blood consists of minute coloured globules or particles, floating in a clear liquid. Other red colouring matters, such as madder, cochineal, or lac, do not owe their colour to independent corpuscles or globules. Hence if coloured globules, of the form and size of those found in mammalian blood, are visible under the microscope, there can be no doubt that the liquid is blood. Such evidence can, however, be safely received only from one who has been accustomed to the use of this instrument.

The examination of a blood-stain in the dry state may be made with a power of from twenty to thirty diameters. Coagula or clots not visible to the naked eye, will then plainly appear. These will be found to have a rich crimson-red colour in the thinner portions: the tint, when compared with other red colouring matters, is sufficiently peculiar to enable the examiner to form an opinion, whether the stain be or be not owing to blood. The discovery of coagula or clots, fixed in the fibres of the stuff, is also a strong proof of the stain being caused by blood. Red colours do not give this clotted appearance; but they have merely that of a dried dye, tinging the stuff uniformly without stiffening the fibre. Small portions of kina derived from a solution of that extract, have presented a very strong resemblance to coagula or clots of blood. The action of a persalt of iron on a solution of the stain in water, by striking a greenish black colour, will, however, show that this extract is really the cause of the stain.
In order to examine the stain for globules, a portion of it cut out, or what is better a small fragment of the supposed clot, should be placed on a glass slide and moistened with pure glycerine sufficiently diluted, i.e. brought to a sp. gr. of about 1·030: it is thus rendered a good substitute for the serum of blood. After a short time, the liquid, supposing the stain to be owing to blood, will acquire a reddish or reddish-brown colour. A piece of thin microscopic glass should then be placed over it, and the liquid examined by a power of from 260 to 300 diameters. If the stain be owing to mammalian blood, the globules will present a rounded or (in some aspects) lenticular form, and a pale yellowish or reddish colour. They may be measured by the micrometer. Water alters the size and shape of the blood-globules; hence various liquids have been recommended for separating them from the clot. A solution of sugar, of sulphate of soda, common salt, oil and albumen, have been successively employed; but these are evaporable liquids; they become dry and interfere with the observations. By the use of glycerine, I obtained clear evidence of the existence of globules in a minute fragment of blood which had been kept in a dried state for a period of three years. Hence the microscope may be made available for this species of evidence after a long period of time.

That the globules should be preserved in the dry state of coagulum, is not so surprising as the fact that in the humid state these tender structures appear sometimes to resist for a considerable period the ordinary changes of putrefaction. In September, 1851, a small portion of blood was taken from one of the great veins of the heart of a dog, soon after the death of the animal. About a drachm of the serum, containing some of the red globules, was placed in a corked phial, and examined by the microscope, at intervals during a period of nine months. In June, 1852, the blood was dark coloured, and highly offensive, but on examining it by the microscope, the globules still retained their shape and size without any apparent alteration. In other cases I have found them destroyed by putrefaction.

The microscope has been chiefly employed with the view of determining whether the blood be derived from a human being or from an animal. This is an important question which is constantly arising in criminal investigations. When blood is detected on the dress of a person charged with the death of another, it is frequently asserted in the defence, that the bloodstains were caused by his having killed a pig, a sheep, or a bullock, or by his having accidentally handled the dead carcass of some animal. In a few cases, the situation of these stains on different and remote parts of the dress, back and front, as well as in concealed or covered parts, may show that the defence is inconsistent with the facts; but in the large majority, the medical witness will be required to state whether the blood is or
is not human. It has been already observed that there are no chemical differences between the blood of man and animals. The red colouring matter, the albumen and fibrin, are the same, and chemical tests produce on them precisely similar results. The microscopical differences refer to shape and size. 1. With respect to shape. In all animals with red blood, the globules have a disc-like or flattened form. In the mammalia, excepting the camel tribe, the outline of the disc is circular. In this tribe, and in birds, fishes, and reptiles, the globules have the form of a lengthened ellipse or oval. In the three last mentioned classes of animals they have a central nucleus, which gives to them an apparent prominence in the centre. The blood-globules of all the mammalia, including those of the camel tribe, have no central nucleus, and they appear depressed in the centre.

The microscope, therefore, enables the observer to distinguish the blood of birds and fishes from that of a human being; and this is often of great importance as evidence. In the case of Reg. v. Droy (Essex Lent Assizes, 1851), it was suggested in the defence, that the blood-stains on the clothes of the prisoner had been caused by his having killed some chickens. The shape of the globules negatived this part of the defence. In another case the blood was alleged to be that of a fish; this was also disproved by the shape. It is proper to state that water alters the shape of the oval corpuscle, so as to render it larger and to give it a circular outline. Dr. Bennett states that on one occasion he was called to see a patient (labouring under bronchitis) who was spitting florid blood. On examining the sputum with a microscope, he found that the coloured blood-corpuscles were those of a bird. On his telling the patient that she had mixed a bird's blood with the expectoration, she was astounded, and confessed that she had done so for the purpose of imposition. (The Microscope as a Means of Diagnosis, p. 185.)

The only microscopical distinction between the blood of man and domestic animals, consists in a difference in the size of the blood-globules. This, however, is only an average difference; for the globules are found of very different sizes in the blood of the same animal. In making use of this criterion, it would be necessary to rely upon the size of the majority of the corpuscles seen in a given area, and under the same power of the microscope. It is a curious fact that the size of these globules in the blood bears no relation to the size of the animal. Thus in the horse, ox, ass, cat, mouse, pig, and bat, they are on the average nearly of the same size; the difference is so slight as to be practically inappreciable. In these animals they are smaller than in man, and in several of the mammalia. The corpuscles in man, the dog, the rabbit, and the hare, are of nearly the same size. In the blood of the sheep and goat, they are smaller than in other mammalia. The size of the corpuscle bears no proportion to the age
of the animal: thus in the blood of the human foetus they are to be found as large as in that of the adult.

The measured diameter of the globules in human blood varies, according to Gulliver, from 1-2000th to 1-4000th of an inch, the average size in both sexes being 1-3200th of an inch. From the examination of various specimens of human blood, I have found the average diameter of the globules to be the 1-3500th of an inch, the maximum size being 1-3000th, and the minimum 1-5000th of an inch. The globules of human blood are larger than those of domestic animals. The subjoined measurements in fractions of an inch, are those given by Mr. Gulliver, excepting the figures in brackets, which are from my own micrometrical observations. The average diameter is, in the dog, 1-3540th (max. 1-4000th, min. 1-6000th),—in the hare, 1-3607th (1-4000th: max. 1-2000th, min. 1-8000th),—in the mouse, 1-3814th, —in the ass, 1-4000th (rabbit, 1-4000th),—in the pig, 1-4230th (1-4250th),—in the ox, 1-4267th, —(in the cow 1-4000th to 1-4200th),—in the cat, 1-4400th,—in the horse, 1-4600th (1-5000th),—in the sheep, 1-5300th (1-5333rd to 1-6000th),—in the goat, 1-6366th.

These measurements apply to recent blood which has not been allowed to dry on animal and vegetable stuffs. In this case a distinction might be made between the blood of a human being and a sheep. With respect to the dog and the rabbit, it would be, even under these favourable circumstances, a matter of difficulty. When blood is dried on clothing, and it is necessary to extract the corpuscles by means of a liquid of a different nature from the serum, we cannot rely upon slight fractional differences, since we cannot be sure that the globules, after having been dried, will ever reacquire in a foreign liquid the exact size which they had in serum. Medical evidence must therefore be based in such cases on a mere speculation. (See Guy's Hospital Reports, Vol. vii. Pt. ii. 1851.) Dr. Schmidt has proposed to dry the corpuscles of each animal, to measure them in their dried or shrivelled state, and to compare the suspected blood (also dried) with these various samples. (Die Diagnostik verdächtigen Flecken in Criminalfällen, Leipzig, 1848.) I have tried this process, but have not found it practically available. In the present state of science the question must in my opinion be regarded as unsolved. When blood has been dried on clothing, we cannot, with certainty and accuracy, distinguish that of an ordinary domestic animal from the blood of a human being. The extent to which a medical witness is justified in going on such occasions appears to me to be this. The size and shape of the corpuscles are consistent with their being the corpuscles of human blood; but it is impossible in the present state of science to affirm that the corpuscles extracted from stains dried on clothing or weapons are not those of some domestic animal.
This was the substance of the evidence which I gave in the case of Reg. v. Munro (Cumberland Lent Assizes, 1855), a case in which everything turned on circumstantial evidence of a medical and moral kind. I declined to say absolutely that the stains were caused by human blood, although the corpuscles coincided in measurement with them. In one instance a medical witness professed to make a distinction between certain spots on a man’s clothes,—assigning some to the blood of a horse, and others to human blood; but in criminal jurisprudence no one has probably gone so far as Mr. Herapath in a case, on some points of which I have elsewhere commented. (Reg. v. Nation, Taunton Spring Assizes, 1857, see ante, p. 279.) In his evidence this witness is reported to have said, in reference to blood on the clothes of the accused, and on a knife in his possession, that he had compared the globules with those of the ox, sheep, and pig, and they were larger. The difference in size was considerable. The relative sizes of the human and animal corpuscle, he stated, would be as 53 to 34 in the ox, 52 to 34 in the sheep, and 44 to 34 in the pig. Hence he inferred, or led the jury to infer, that it was not the blood of either of these three animals. (Medical Times and Gazette, April 11, 1857, p. 365.) This inference was based on measurements which differ widely from those given by medical authors of repute. Thus Schmidt found the proportions to be 45 to 34 in the ox, 58 to 34 in the sheep, and 42 to 34 in the pig. (Die Diagnostik verdächtigen Flecken in Criminalfällen, p. 48.) The proportions obtained by Friedberg were 37 to 34 in the ox, 40 to 34 in the sheep, and 39 to 34 in the pig. (Histologie des Blutes, p. 46, Berlin, 1852.) We are left to conjecture whether the comparison was made by Mr. Herapath between the wet (recent) blood of the animals, and the dried blood on the knife; but in either case the swearing to minute differences on averages widely differing from averages obtained by others justified the advice of the learned judge (Cockburn) who tried this case, that the jury should not convict on such scientific speculations. It was the same over-confidence in his scientific speculations that led this witness to state on oath, at the trial of William Palmer, in reference to the detection of strychnia in the stomach, “I am certain that I could discover the fifty-thousandth part of a grain.” To one who can speak with such facility and certainty of the differences between living and dead blood,—between human and ox-blood dried on a knife; and who can identify on a bloody weapon epithelial or mucous scales coming from the mucous membrane of a throat (ante, p. 279), nothing can present itself as a difficulty in science. Any deficiencies on the part of this gentleman when summoned as a witness, certainly cannot arise from want of confidence in science, or in his mode of working his results. It must not be expected, however, that such views are acquiesced in or are likely to be adopted by
others; and if a case occurred in which a conviction turned upon such evidence in the absence of other satisfactory proofs, it is quite certain that those who have made this department of physiology a special study, would at once come forward to refute statements so fallacious and untrustworthy as these. In the meantime their promulgation in the newspapers enables a person upon his own assertion to advertise himself as possessed of peculiar powers of analysis and research, not possessed by others who are working in the same branch of science. The most recent information on this important subject will be found in Ritter's Prize Essay, Ueber die Ermittelung der Blutflecken in Kriminalfällen, Würzburg, 1854, and Friedberg's Histologie des Blutes, Berlin, 1852. These authors affirm from their observations, that it is not possible to distinguish by the microscope human from animal blood in criminal cases. Evidence based upon such varying averages as those above given, must be treated as speculative and unsafe.

CHAPTER XXVIII.

DEATH OF WOUNDED PERSONS FROM NATURAL CAUSES—DISTINCTION BETWEEN REAL AND APPARENT CAUSE—DEATH FROM WOUNDS OR LATENT DISEASE—ACCELERATING CAUSES—WHICH OF TWO WOUNDS CAUSED DEATH?—DEATH FOLLOWING SLIGHT PERSONAL INJURIES.

Death of wounded persons from natural causes.—It is by no means unusual for individuals who have received a wound, or sustained some personal injury, to die from latent natural causes; and as, in the minds of non-professional persons, death may appear to be a direct result of the injury, the case can only be cleared up by the assistance of a medical practitioner. Such a coincidence has been witnessed in many instances of attempted suicide. A man has inflicted a severe wound on himself while labouring under disease; or some morbid change, tending to destroy life, has occurred subsequently to the infliction of a wound, and death has followed. Without a careful examination of the body, it is impossible to refer death to the real cause. The importance of an accurate discrimination in a case in which a wound or personal injuries have been caused by another, must be obvious on the least reflection; a hasty opinion may involve an accused party in a charge of manslaughter; and although a barrister might be able to show on the trial that death was probably attributable not to the wound, but to coexisting disease, yet it must be remembered, that the evidence of a surgeon before a coroner, in remote parts of this country, may be the means of causing the accused to remain incarcerated for a period of five,
six, or seven months previously to the trial. This is in itself a punishment, independently of the loss of character, to which the accused must be in the meantime exposed.

In Gay's Hospital Reports, Oct. 1850, p. 230, will be found two cases communicated to me by Mr. Procter, of York, in which death from natural causes was wrongly assigned to violence. In a very instructive case, reported by Dr. Berneastle (Lancet, Feb. 15, 1845, p. 183), the deceased, a boy, died, from internal strangulation of the intestine from morbid causes, after wrestling with another boy, who might, but for the inspection, have been erroneously charged with having caused his death. (For a similar case, see Medical Gazette, xxxvii. p. 702.) An instance is related by Dr. Neumann, in which the question was, however, doubtful. (See Casper's Wochenschrift, May 24, 1845.)

Death from wounds or latent disease.—It must be borne in mind by a practitioner, that numerous causes of death may be lurking within the body at the time that a wound is criminally inflicted, and a close attention to the symptoms and appearances after death can alone assist him in the difficult position in which he may be placed, should the accused party be subsequently brought to trial. A man may be severely wounded, and yet death may take place from rupture of the heart, the bursting of an aneurism, from apoplexy, phthisis, or other morbid causes which it is here unnecessary to specify. (Cormack's Ed. Journal, May 1846, p. 343.) If death can be clearly traced to any of these diseases by an experienced surgeon, the prisoner cannot be charged with manslaughter; for the medical witness may give his opinion that death must have taken place about the same time and under the same circumstances whether the wound had been inflicted or not. The case of Colonel Gordon, which occurred in April 1854, proves that slight causes may lead to death, when there is latent disease of the heart or any other important organ. This case was the subject of a trial at the Chester Lent Assizes, 1854 (Reg. v. Smadurs). It appeared from the evidence, that the prisoner, who was the conductor of a railway train in which deceased was travelling, attempted to eject him from a carriage. The deceased resisted, and in the struggle the prisoner struck him on the left arm. The deceased made no further resistance, but sat quietly in his seat. It was soon afterwards perceived that he was dead. The medical evidence showed that there was ossification of the valves of the heart and aorta, and that this disease had been of long standing. The life of the deceased was at all times in great peril, and his death might have arisen from the excitement which took place previous to the prisoner laying hands upon him. It might have followed in the course of half an hour. As it was thus admitted that excitement alone would account for the fatal result, the prisoner was acquitted. There was no corporal injury done to the deceased which could account for death.
In another case, which was the subject of a trial at the Central Criminal Court, in June 1854 (Reg. v. Champlonier), appearances sufficient to account for death existed in the part which sustained the violence; but the medical witness could not with certainty refer them to the violence. An old man passing along a road was struck on the forehead by a stone thrown by the prisoner. The surgeon stated that there was a contused wound, and that his nose bled profusely. The bleeding was arrested, and on the following day he considered the deceased to be out of danger. At a later period of the day, however, the deceased was seized with an apoplectic fit, from which he did not recover. The appearances in the brain were quite sufficient to account for death; but he could not undertake to say that the injury by the stone had in any way produced the appearances. Upon this evidence the supposed connection of the death with the violence was at once set aside, and the prisoner was discharged.

On these occasions, one of the following questions may arise: — Was the death of the party accelerated by the wound, or was the disease under which he was labouring so aggravated by the wound as to produce a more speedy fatal termination? The answer to either of these questions must depend on the circumstances of the case, and the witness's ability to draw a proper conclusion from these circumstances. The maliciously accelerating of the death of another already labouring under disease is criminal; for that which accelerates, causes. Lord Hale, in remarking upon the necessity of proving that the act of a prisoner caused the death of a person, says: — "It is necessary that the death should have been occasioned by some corporeal injury done to the party by force, or by poison, or by some mechanical means which occasion death; for although a person may, in foro conscientiae, be as guilty of murder by working on the passions or fears of another, and as certainly occasion death by such means, as if he had used a sword or pistol for the purpose, he is not the object of temporal punishment." (I. 247.) Several acquittals have taken place of late years, in cases in which the deaths of parties had been occasioned by terror, or dread of impending danger, produced by acts of violence on the part of the prisoners; not, however, giving rise to bodily injury in the deceased. Conformably to Lord Hale's view, the Criminal Law Commissioners in their report on the subject of homicide, state: — "Art. 1. The law takes no cognizance of homicide unless death result from bodily injury occasioned by some act or unlawful omission, as contradistinguished from death occasioned by an influence on the mind, or by any disease arising from such influence. Art. 2. The terms 'unlawful omission' comprehend every case where any one being under legal obligation to supply food, clothing, or other aid and support, or to do any other act, or make any other provision for
WHICH OF TWO WOUNDS CAUSED DEATH.

325

the sustentation of life, is guilty of any breach of such duty." Under the statute (1 Vict. c. 85, s. 2) it appears from the following case that physical injury only is intended. In this case (Reg. v. Gray, Huntingdon Lent Assizes, 1857), the prisoner was indicted for causing a bodily injury dangerous to life—to wit, a congestion of the lungs and heart, with intent to murder. It appeared that she had exposed her child to cold and wet, and that congestion or inflammation of the lungs was a result of such exposure. Erle J. held that the statute under which the indictment was laid contemplated the infliction of some wound or visible injury to the person. The woman was found guilty; but in June 1857, the point having been reserved, the conviction was quashed by the Court for Crown Cases reserved, on the ground that, looking to the other offences provided for in this statute, this case did not come within it. In the case of Reg. v. Percival (Midland Circuit, March 1857) a man was charged with the manslaughter of deceased by causing his death from fright, i.e. by personating a ghost. The evidence showed that the boy had sustained no physical injury, but he had received a shock from which he did not recover. Wightman J. held that in his view the case would fall within the definition of manslaughter.

Under the new statute (14 and 15 Vict. cap. 100), the necessity for tracing death to some corporeal injury appears to be practically abolished. According to the fourth section, in any future indictment for murder or manslaughter it shall not be necessary to set forth the manner in which or the means by which the death of the deceased was caused.

Which of two wounds caused death.—It is possible that a man may receive two wounds on provocation, at different times, and from different individuals, and die after the receipt of the second: in such a case, the course of justice may require that a medical witness should state which wound was the cause of death. Let us take the following illustration:—A man receives during a quarrel a gun-shot wound in the shoulder. He is going on well, with a prospect of recovery, when in another quarrel he receives a severe penetrating wound in the chest or abdomen from another person, and after lingering under the effects of these wounds for a longer or shorter period, he dies. If the gun-shot wound were clearly shown to have been the cause of death, the second prisoner could not be convicted of manslaughter; or if the stab were evidently the cause of death, the first prisoner would be acquitted on a similar charge. It might be possible for a surgeon to decide the question summarily, when, for instance, death speedily followed the second wound; and, on inspection of the body, the heart or a large vessel is discovered to have been penetrated; or, on the other hand, extensive sloughing sufficient to account for death, might take place from the gun-shot wound, and on inspection, the stab might be found to be of a slight
nature,—not involving any vital parts. In either of these cases, all would depend upon the science and skill of the medical practitioner,—his evidence would be so important that no correct decision could be arrived at without it; he would be, in fact, called upon substantially to distinguish the guilty from the inno-
cent. On some occasions death may appear to be equally a con-
sequence of either or of both of the wounds; in which case, pro-
ably, both parties would be liable to a charge of manslaughter.
(See Ann. d'Hyg. 1835, ii. 432.) The second wound, which is here supposed to have been the act of another, may be inflicted by the wounded party on himself, in an attempt at suicide, or it may have an accidental origin. The witnesses would then have to determine whether the wounded party died from the wound inflicted by himself or from that which he had previously re-
ceived. (See Tetanus, post.)

It may happen that the wounded person has taken poison, and actually died from the effects of this, and not from the injuries or maltreatment. Cases of this kind have been already related (page 235). Again: a wounded person may have been the subject of further ill-treatment, and the question will be put as to which of the two causes his death was really due. It is to be observed of these cases, that the supervening disease, the poison, or the subsequent ill-treatment, should be of such a nature as to account for sudden or rapid death: since it would be no answer to a charge of death from violence, to say that there were marks of chronic disease in the body, unless it were of such a nature as to account for the sudden destruction of life under the symp-
toms which actually preceded death. In the medical jurispru-
dence of wounds, there is probably no question which so fre-
quently presents itself as this: it is admitted that the violence was inflicted, but it is asserted that death was due to some other cause: and the onus of proof lies on the medical evidence. Among numerous cases which have occurred in England during the last twelve years, I find that the latent causes of death in wounded persons have been chiefly inflammation of the thoracic or abdominal viscera, apoplexy, diseases of the heart and large blood-vessels, phthisis, ruptures of the stomach and bowels from disease, internal strangulation, and the rupture of deep-seated abscesses. In some of these cases the person was in a good state of health up to the time of the violence, and in others there was a slight indisposition. The history is nearly the same in all: it was only by careful conduct on the part of the medical witnesses that the true cause of death was ascertained. It is obvious that questions of malapraxis and life-insurance, giving rise to civil actions, may have a close relation to this subject.

Death following slight personal injuries.—An imputation has often been thrown on the masters of schools, when boys have died soon after they have been chastised. In such cases there
has been commonly some unhealthy state of the body to explain this result. When the disease which gives rise to doubt is seated in a part which is remote from that which sustained the violence, all that is required is, that the examination of the body should be conducted with ordinary care. If the disease should happen to be in the part injured, the case is much more perplexing. The difficulty can then be removed only by attentively considering the ordinary consequences of such injuries. The violence may have been too slight to account for the diseased appearance; and the disease itself, although situated in the part injured, may be regarded as an unusual consequence of such an injury.

CHAPTER XXIX.

WOUNDS INDIRECTLY FATAL.—DEATH FROM WOUNDS AFTER LONG PERIODS—SECONDARY CAUSES OF DEATH—THE CAUSE IS UN-AVOIDABLE—THE CAUSE AVOIDABLE BY GOOD MEDICAL TREATMENT—COMPARATIVE SKILL IN TREATMENT—CAUSE AVOIDABLE BUT FOR IMPRUDENCE ON THE PART OF THE WOUNDED PERSON—ABNORMAL OR UNHEALTHY STATE OF BODY—ACCELERATION OF DEATH.

Wounds indirectly fatal.—Certain kinds of injuries are not immediately followed by serious consequences, but the individual may perish after a longer or shorter period of time, and his death may be as much a consequence of the injury as if it had taken place on the spot. The aggressor, however, is just as responsible as if the deceased had been directly killed by his violence, provided the fatal result can be traced to the usual and probable consequences of the injury. Wounds of the head are especially liable to cause death insidiously: the person may in the first instance recover,—he may appear to be going on well, when, without any apparent cause, he will suddenly expire. It is scarcely necessary to observe, that in general an examination of the body will suffice to determine whether death is to be ascribed to the wound or not. In severe injuries affecting the spinal marrow, death is not an immediate consequence, unless that part of the organ which is above the origin of the phrenic nerves be wounded. Injuries affecting the lower portion of the spinal column do not commonly prove fatal until after some time; but the symptoms manifested by the patient during life, as well as the appearances observed in the body after death, will sufficiently connect the injury with that event. Death may follow a wound, and be a consequence of that wound, at almost any period after its infliction. It is necessary, however, in order to maintain a charge of homicide against an individual, that death
should be strictly and clearly traceable to the injury, and not be dependent on any other cause. A doubt on this point must, of course, lead to an acquittal.

Death from wounds after long periods.—Many cases might be quoted in illustration of the length of time which may elapse before death takes place from certain kinds of injuries—the injured party having ultimately fallen a victim to their indirect consequences. A case is related by Sir A. Cooper, of a gentleman who died from the effects of an injury to the head received about two years previously. In this case the connection of death with the wound was clearly made out by the continuance of the symptoms of cerebral disturbance during the long period which he survived.

There is a singular rule in our law relative to the period at which an individual dies from a wound—namely, that a party shall not be adjudged guilty of homicide, unless death take place within a year and a day after the infliction of a wound. (Archbold, p. 345.) In practice, the existence of this rule is of little importance, but in principle it is erroneous. Most wounds leading to death generally destroy life within two or three months after their infliction:—sometimes the person does not die for five or six months, and, in more rare instances, death does not ensue until after the lapse of twelve months, or even several years. These protracted cases occur especially in respect to injuries of the head. Strict justice demands that the responsibility of a person who has inflicted a wound should depend upon its having really caused death, and not upon the precise period at which death takes place; for this must be a purely accidental circumstance.

Secondary causes of death.—An individual who recovers from the immediate effects of a wound may die from fever inflammation or its consequences, erysipelas, delirium tremens, tetanus, or gangrene; or an operation required during the treatment of a wound may prove fatal. These are what may be called secondary causes of death, or secondary consequences of a wound. The power of deciding on the responsibility of an accused person for an event which depends only in an indirect manner on an injury originally inflicted by him, rests, of course, with the authorities of the law. But it is impossible that they can decide on so difficult and nice a question in the absence of satisfactory medical evidence; and on the other hand, it is right that a medical witness should understand the importance of the duty here required of him. Fever or erysipelas may follow many kinds of serious wounds, and in some few instances be distinctly traceable to them; but in others, the constitution of a patient may be so broken up by dissipated habits as to render a wound fatal which in a healthy subject might have run through its course mildly, and have healed. When the fever or erysipelas can be traced
to a wound, and there is no other apparent cause of aggravation to which either of these disordered states of the body could be attributed, they can scarcely be regarded by the medical practitioner as very unexpected and unusual consequences, especially when the injury is extensive, and seated in certain parts of the body, as the scalp. If death take place under these circumstances, the prisoner will be held as much responsible for the result as if the wound had proved directly mortal. This principle has been frequently admitted by our law, and, indeed, were it otherwise, many reckless offenders would escape, and many lives would be sacrificed with impunity. It is, however, difficult to lay down general rules upon a subject which is liable to vary in its relations in every case; but when a wound is not serious, and the secondary cause of death is evidently due to constitutional peculiarities from acquired habits of dissipation, the ends of justice are probably fully answered by an acquittal; in fact, such cases do not often pass beyond a coroner’s inquest.

The secondary causes of death may be arranged under the following heads:—

1. The cause is unavoidable.—Of this kind are tetanus, following laceration of tendinous and nervous structures, erysipelas following lacerated wounds of the scalp, peritoneal inflammation following rupture of the bladder or intestines, with effusion of their contents, strangulation of the intestines, as phrenic hernia, following rupture of the diaphragm, and others of the like nature. Here, supposing proper medical treatment and regimen to have been pursued, the secondary cause of death was unavoidable, and the fatal result certain.

2. The cause avoidable by good medical treatment.—There are, it is obvious, many kinds of wounds which, if properly treated in the first instance, may be healed, and the patient recover; but when improperly treated, they may prove fatal. In the latter case, it will be a question for a witness to determine how far the treatment aggravated the effects of the violence, and from his answer to this the jury may have to decide on the degree of criminality which attaches to a prisoner. Let us suppose, for instance, that an ignorant person has removed a clot of blood, which sealed up the extremity of a vessel, in consequence of which fatal hemorrhage has ensued,—or that he has produced death by unnecessarily interfering with a penetrating wound of the chest or abdomen,—it would scarcely be just to hold the aggressor responsible, since, but for the gross ignorance and unskilfulness of his attendant, the wounded party might have recovered from the effects of the wound. When death is really traceable to the negligence or unskilfulness of a surgeon who is called to attend on a wounded person, this circumstance ought to be, and commonly is, admitted in mitigation, supposing that the wound was not originally of a mortal nature. Lord Hale ob-
serves: "It is sufficient to constitute murder, that the party dies of the wound given by the prisoner, although the wound was not originally mortal, but became so in consequence of negligence or unskilful treatment; but it is otherwise where death arises not from the wound, but from unskilful applications or operations used for the purpose of curing it." (I. 428.) The medical jurist will perceive that a very nice distinction is here drawn by this great judge, between death as it results from a wound rendered mortal by improper treatment, and death as it results from the improper treatment, irrespective of the wound. In the majority of cases such a distinction could scarcely be established, except upon speculative grounds, and in no case, probably, would there be any accordance in the opinions of medical witnesses. In slight and unimportant wounds, it might not be difficult to distinguish the effects resulting from bad treatment from those connected with the wound, but there can be few cases of severe injury to the person, wherein a distinction of this nature could be safely made; and the probability is, that no conviction for murder would now take place, if the medical evidence showed that the injury was not originally mortal, but only became so by unskilful or improper treatment. In such a case, it would be impossible to ascribe death to the wound, or to its usual or probable consequences,—and without this it is not easy to perceive on what principle an aggressor could be made responsible for the result.

3. Comparative skill in treatment.—If death be owing to a wound, it signifies not that, under more favourable circumstances, and with more skilful treatment, a fatal result might have been averted. As a proof of this, the following case, reported by Alison, may be quoted:—The prisoner was one of a party of smugglers who fired at an officer of excise. The wounded man was carried to the nearest village, where he was attended by a surgeon of the country, who was not deficient in attention; but a great collection of matter having formed in the leg, fever ensued, and the patient died at the end of three weeks. In defence, it was urged that, by skilful treatment, the man might have recovered; but the Court held that it was incumbent to prove that death arose ex malo regimine. The true distinction in all such cases is, that if the death was evidently occasioned by grossly erroneous medical treatment, the original author of the violence will not be answerable; but if it arise from the want merely of the higher skill which can only be commanded in great towns, he will be responsible, because he has wilfully exposed the deceased to a risk from which he had practically no means of escaping. (p. 150.) In the case of Macewon (Perth, Sept. Cir. 1830), the prisoner was indicted for the manslaughter of a boy, by striking him a blow on the shoulder, which dislocated the arm. Two days after the blow, an ignorant bone-
setter was consulted, and owing to his manipulations, inflammation took place, and the boy being of a sickly and scrofulous habit, this proved fatal. Under the direction of Lord Meadowbank the prisoner was acquitted. In charging the grand jury, in reference to Mr. Seton's case (Winchester Aut. Ass. 1845), Baron Platt is reported to have observed, that if a man inflict a wound likely to produce death, and the wounded party should fall into the hands of an unskilful practitioner, whereby death was hastened, the aggressor would still be responsible for the result. If the wound had not been likely to produce death, but by unskilful treatment death ensued, then that would not be murder.

It will be obvious that a serious responsibility is thrown on practitioners who undertake the management of a case of criminal wounding. Any deviation from common practice should therefore be made with the greatest caution, since novelties in practice will, in the event of death, form one of the best grounds of defence in the hands of a prisoner's counsel. On these occasions, every point connected with the surgical treatment will be rigorously inquired into. In the case of a severe lacerated wound to the hand or foot, followed by fatal tetanus, it may be said that the wounded person would not have died, had amputation been performed. In this instance, however, a practitioner may justify himself by showing either that the injury was too slight to require amputation, or that the health or other circumstances connected with the deceased would not allow of its being performed with any reasonable hope of success. On the other hand, if the practitioner performed amputation, and the patient died, then it would be urged that the operation was unjustifiable and had caused death. Here the surgeon is bound to show that the operation was necessary, according to the ordinary rules of treatment. The treatment of severe incised wounds of the throat, when the trachea is involved, sometimes places a practitioner in an embarrassing position. If the wound be left open, death may take place from hemorrhage: if it be prematurely closed, blood may be effused into the trachea, and cause death by suffocation.

4. The cause avoidable but for imprudence or neglect on the part of the wounded person.—A man who has been severely wounded in a quarrel, may obstinately refuse medical assistance, or he may insist upon taking exercise, or using an improper diet, contrary to the advice of his medical attendant; or, by other imprudent practices, he may thwart the best conceived plans for his recovery. The neglect to call in a medical practitioner, or the refusal to receive medical advice, will not, however, according to the decision in the case of Reg. v. Thomas (Gloucester Aut. Ass. 1841), be considered a mitigatory circumstance in favour of the prisoner, even although the wound was susceptible of being cured. A man may receive a lacerated wound of an extremity,
which is followed by tetanus or gangrene, and thus prove fatal: he may have declined receiving medical advice, or have obstinately refused amputation, although proposed by his medical attendant; but this would not be received as a mitigatory circumstance on the part of a prisoner; because the wounded person is not compelled to call for medical assistance, or to submit to an operation, and a medical witness could not always be in a condition to swear that the operation would have positively saved his life; he can merely affirm that it might have afforded to the deceased a chance of recovery. In the case of the Queen v. Hulme (Liverpool Aut. Assizes, 1843), it was proved that the deceased had died from tetanus, caused by an injury to a finger some time before. Amputation was advised by the surgeon, but the deceased would not consent to the operation. The prisoner was convicted of manslaughter, and sentenced to the severest punishment prescribed by the law for that crime.

5. The cause avoidable but for an abnormal or unhealthy state of the body of the wounded person.—Wounds which are comparatively slight sometimes prove indirectly fatal, owing to the person being in an unhealthy state at the time of their infliction. In bad constitutions, compound fractures or slight wounds, which in a healthy subject would have a favourable termination, are followed by gangrene, fever, or erysipelas, proving fatal. Here the responsibility of an assailant for the death may become reduced, so that, although found guilty of manslaughter, a mild punishment might be inflicted. The consequence may be, medically speaking, unusual or unexpected, and, but for circumstances wholly independent of the act of the accused, would not have been likely to destroy life. In general, in the absence of malice, this appears to be the point to which the law closely looks, in order to make out the responsibility of the accused—that, namely, that the fatal secondary cause must be something not unusual or unexpected as a consequence of this particular injury; and the medico-legal question presents itself under this form:—Would the same amount of injury have been likely to cause death in a person of ordinary health and vigour? Men who have suddenly changed their habits of living, and have passed from a full diet to abstemiousness, are unable to bear up against comparatively slight injuries, and often sink from the secondary consequences. So a man otherwise healthy labouring under hernia, may receive a blow in the groin, attended with rupture of the intestine, gangrene and death,—another with a calculus in the kidney may be struck in the loins, and die in consequence of the calculus perforating the renal vessels and causing fatal hemorrhage, or from subsequent inflammation. In the case of Bennett v. Gredley (Exchequer Sittings, Hilary Term, 1854), which was a suit for compensation by reason of injuries inflicted on a boy's arm, it was urged in defence that the state of
the arm was partly owing to a former injury; in reference to
which the Chief Baron remarked, that a man was not bound to
have his body in so sound and healthy a state as to warrant an
unauthorised assault upon him. A man, therefore, who com-
mitted an unauthorised assault upon his fellow-man must take
his chance of the effects which such an assault might produce.

Acceleration of death.—It must be evident that there exist
numerous other internal diseases, such as aneurism, and various
morbid affections of the heart and brain, which are liable to be
rendered fatal by slight external violence. Now, the law, as
applied to these cases, is thus stated by Lord Hale:—“It is suf-
ficient to prove that the death of the party was accelerated by
the malicious act of the prisoner, although the former laboured
under a mortal disease at the time of the act.” (I. 428.) In
those cases in which a slight degree of violence has been followed
by fatal consequences, it is for a jury to decide, under all the cir-
cumstances, upon the actual and specific intention of the prisoner
at the time of the act which occasioned death. And, accord-
ing to Starkie, “it seems that in general, notwithstanding any facts
which tend to excuse or alleviate the act of the prisoner, if it be
proved that he was actuated by prepense and deliberate malice,
and that the particular occasion and circumstances upon which
he relies were sought for and taken advantage of merely with a
view to qualify actual malice, in pursuance of a pre-conceived
scheme of destruction, the offence will amount to murder.” In
most of these cases there is an absence of intention to destroy
life; but the nature of the wound, as well as the means by which
it was inflicted, will often suffice to develop the intention of the
prisoner. An accurate description of the injury, if slight, may
afford strong evidence in favour of a prisoner, since the law does
not so much regard the means used by him to perpetrate the
violence, as the actual intention to kill, or to do great bodily
harm. Serious injury, causing death by secondary consequences,
will admit of no exculpation, when the prisoner was aware, or
ought to have been aware, of the condition of the party whom
he struck. Thus, if a person notoriously ill, or a woman while
pregnant, be violently maltreated, and death ensue from a sec-
dary cause, the assailant will be held responsible; because he
ought to have known that violence of any kind to persons so
situated must be attended with dangerous consequences. So, if
the person maltreated be an infant, or a decrepit old man, or one
labouring under a mortal disease, it is notorious that a com-
paratively slight degree of violence will destroy life in these
cases; and the prisoner would properly be held responsible. A
wound which accelerates death causes death, and may therefore
render the aggressor responsible for murder or manslaughter,
according to the circumstances. The Commissioners lately ap-
pointed to define the criminal law on the subject of homicide.
thus express themselves:—"Art. 3. It is homicide, although the effect of the injury be merely to accelerate the death of one labouring under some previous injury or infirmity, or although, if timely remedies or skilful treatment had been applied, death might have been prevented." This is conformable to the decisions of our judges. According to Lord Hale, if a man have a disease which in all likelihood would terminate his life in a short time, and another give him a wound or hurt which hastens his death, this is such a killing as constitutes murder. (Archbold, p. 345; see ante, p. 324.)

CHAPTER XXX.

WOUNDS INDIRECTLY FATAL. TETANUS FOLLOWING WOUNDS—
LATENT CAUSES OF—DEATH FROM SURGICAL OPERATIONS—
PRIMARY AND SECONDARY CAUSES OF DEATH—UNSKILFULNESS
IN OPERATIONS—NECESSITY FOR THE OPERATION—ERYSIPelas
FOLLOWING OPERATIONS—DELIRIUM TREMENS.

Tetanus following wounds.—Tetanus frequently presents itself as a secondary fatal consequence of wounds,—especially of those which are lacerated or contused, and affect nervous or tendinous structures. It has often occurred as a result of very slight bruises or lacerations, when the injury was so superficial as to excite no alarm; and it is a disease which gives no warning of its appearance. Dr. Brady met with a case in which a man slipped in walking, and fell flat on his back. He was stunned, but able to walk home. He apparently recovered from this simple accident, but on the following day he was attacked with tetanus and died in seventy hours. (Lancet, May 15, 1847, p. 516.) In the case of Reg. v. Butcher (Warwick Lent Assizes, 1848), it was proved by the medical evidence that the deceased had received a blow on the nose, which caused severe bleeding. In spite of good surgical treatment, the man was attacked with tetanus on the fifteenth day, under which he sank. On inspection, it was found that one of the small bones of the nose had been broken, and this had given rise to the fatal attack. Tetanus may come on apparently from spontaneous causes, i.e. independently of the existence of any wound on the body. In this form it is called idiopathic, to distinguish it from the tetanus of wounds, which is called traumatic. Many cases have been brought into the London hospitals, in which the only cause of this disease appeared to be exposure to cold or wet,—or in some instances, exposure to a current of air. (Lancet, Dec. 14, 1844, p. 351.) Dr. Watson met with a case in which tetanus appeared in a severe form in a man who had received no wound, but who had been simply exposed.
LATENT CAUSES OF TETANUS.

It is scarcely possible to distinguish, by the symptoms, tetanus from wounds from that which occurs spontaneously as a result of natural causes. In endeavouring to connect its appearance with a particular wound or personal injury, it will be proper to observe—1, whether there were any symptoms indicative of it before the maltreatment; 2, whether any probable cause could have intervened to produce it, between the time of its appearance and the time at which the violence was inflicted; —3, whether the deceased ever rallied from the effects of the violence. The time at which tetanus usually makes its appearance, when it is the result of a wound, is from about the third to the sixth day. When resulting from a wound it is generally fatal.

A medical practitioner is bound to exercise great caution before he pronounces an opinion that a fatal attack of tetanus has arisen either from spontaneous causes or from slight blows or personal injuries. A case occurred in St. Bartholomew’s Hospital, in September 1833, which exemplifies the necessity of making a rigorous inquiry into all the attendant circumstances. A boy, aged 15, while quarrelling with another, received a blow in the back from his companion’s fist, and this was followed by a kick, but not of a severe character. He was able to get up and walk home; in about two hours he complained of stiffness about the jaw. He passed a restless night,—the stiffness increased; there was great pain, and subsequently difficulty of swallowing. On the second day he was admitted into the hospital,—the pain and stiffness gradually increased, and the jaw became partially fixed. Spasm of the muscles of the back supervened, occurring in paroxysms, and there was confirmed tetanus. He died on the fourth day after he had received the blow on the back, and apparently from tetanus as a result of that violence: it turned out, however, on inquiry, that six days previously to the first appearance of the tetanic symptoms, the boy had accidentally driven a rusty nail into his foot, and that the suppurating wound which resulted from this injury had only closed on the day on which the blow was inflicted. On an examination of the body a small pucker’d cicatrix, such as would result from the healing of a punctured wound, was found on the ball of the great toe, and there could be no doubt from the circumstances, that this, and not the slight blows struck by the assailant, had been the cause of the fatal attack of tetanus. (See Lancet, Dec. 10, 1833, p. 550.) This case has an important bearing on the question considered at p. 325. It is probable that many cases have been set down as idiopathic tetanus in which, by proper inquiry, the disease might have been traced to a wound or some personal injury. In one instance the tetanus was at first considered to be idiopathic: but shortly before death a small black mark was observed on the thumb-nail. On making inquiry, it was found
that a few days previously to the attack a splinter of wood had accidentally penetrated the thumb. The patient attached so little importance to the accident that he did not mention the circumstance to his medical attendant. This was no doubt the cause of the disease.

Death from surgical operations. — In the treatment of wounds, surgical operations are occasionally resorted to, and a wounded person may die either during the performance of an operation, or from its after-consequences. A question may then arise, whether the party who inflicted the wound shall be held responsible for the fatal result. The law regards a surgical operation as part of the treatment, and if undertaken bona fide, and performed with reasonable care and skill, the aggressor will be held responsible, whatever may be the result. The necessity of the operation, and the mode of performing it, will be left to the operator's judgment. As the defence may turn upon the operation having been performed unnecessarily, and in a bungling and unskilful manner, it will be right for a practitioner, if possible, to defer it until he has had the advice and assistance of other practitioners. According to Lord Hale, if death takes place from an unskilful operation, performed for the cure of a wound, and not from the wound, the responsibility of the prisoner ceases; but this eminent lawyer does not appear to have considered that death may take place as a consequence of the most skilful operation required for the treatment of a wound, and yet be wholly independent of the wound itself.

Should an operation be unnecessarily or unskilfully performed, the responsibility of an aggressor would, it is presumed, cease, if the death of a wounded party could be clearly ascribed to it. Thus, if in carelessly bleeding a wounded person, the brachial artery should be laid open (see Ann. d'Hyg. 1834, ii. 445), or if, in performing amputation, a large artery be improperly secured, so that the patient in either case dies from loss of blood, the prisoner could not be equitably held responsible; because it would be punishing him for an event depending on the unskilfulness of the medical practitioner. According to Baron Platt (p. 331), a prisoner will be held responsible, if the original wound were likely to produce death, although unskilfully treated. Supposing the bleeding or amputation to be performed with ordinary care and skill,—and yet, in the one case inflammation of the veins, and in the other tetanus, gangrene, or fever, should destroy life, the prisoner will be liable for the consequences. The practice of the law is strictly consistent with justice. Should the operation be considered to be absolutely required for the treatment of a wound, which according to all probability would prove mortal without it,—should it be performed with ordinary skill, and still death ensue as a direct or indirect consequence, it is only just that the person who inflicted the injury should be held responsible
Erysipelas following operations. — When a wounded person is taken to an hospital in which gangrene or erysipelas is diffusing itself by infectious propagation, and he is attacked by one of these diseases before or after the performance of an operation, and dies, a prisoner may be held responsible for the fatal result. It might be contended, that the transportation of the wounded man to such a locality was not absolutely necessary to the preservation of his life, and that he would not then have died, but for the accidental presence of an infectious disease. Cases of this kind cannot be easily decided by general rules: but the question has already been raised before a legal tribunal, in a trial which took place at the Maidstone Lent Assizes, 1839. (The Queen against Connel and others.) The deceased was assaulted by a number of soldiers, and received two blows on the head with a stick. The wound was not of any great extent, and the deceased did not appear to suffer much from it. Two days afterwards, he was attacked by erysipelas in the head and face, and he died in about a week. On inspection, there was no appearance of disease. The surgeon referred death to erysipelas, which was prevalent in the hospital at the time the deceased was brought in. The man would probably have recovered but for the attack of erysipelas, and he did not think that he would have been attacked by that disease but for the wound. Erysipelas was an infectious disease, and a common consequence of wounds of the head. Upon this evidence the prisoners were convicted.

Delirium tremens.—An attack of debrium tremens may sometimes follow the injury, or the operation required for its treatment, and destroy life. (Lancet, Jan. 20, 1855, p. 77.)

Questions relative to responsibility in death following operations would come more frequently before Courts of law, were it not that the cases are stopped in the Coroners' courts by verdicts of accidental death. (See Med. Gaz. xix. p. 157.) It unfortunately happens that on these occasions there is great difference of opinion among medical witnesses respecting the connection of the disease with the death, or, indeed, the necessity for the operation itself. The evidence of opinion in favour of the prosecution is sometimes exactly balanced by that urged in
the defence: and under these circumstances, the only course open to the Court, is to discharge the accused. Differences of opinion upon these subjects among members of the profession tend to convey to the public the impression that there are no fixed principles upon which medical opinions are based; and, consequently, that it would be dangerous to act upon them. Thus it is that we are accustomed to hear of a medical prosecution and a medical defence, as if the whole duty of a medical jurist consisted in his making the best of a case, on the side for which he happens to be engaged, — adopting the legal rule for suppressing those points which are against him, and giving an undue prominence to others which may be in his favour. This is an unfortunate condition of things, for which at present there appears to be no other remedy than that of appointing a Medical Board of competent persons to whom such questions might be referred, in the same way as questions relative to navigation are referred by the Admiralty Courts to a board formed of members of the Trinity House,—professionally acquainted with the matters in litigation.

CHAPTER XXXI.

CICATRIZATION OF WOUNDS—EVIDENCE FROM CICATRICES—CHANGES IN AN INCISED WOUND—CICATRICES OF STAB AND GUN-SHOT WOUNDS—DATE OF PRODUCTION—IS A CICATRIX ALWAYS A CONSEQUENCE OF A WOUND?—ARE CICATRICES, WHEN ONCE FORMED, INDELIBLE?—CHARACTERS OF CICATRICES—DATE OF CICATRICES FROM DISEASE OR WOUNDS—MEDICAL EVIDENCE RESPECTING THE PERIOD AT WHICH A WOUND WAS INFlicted—CHANGES OF COLOUR IN CONTUSIONS—HOW LONG DID THE DECEASED SURVIVE THE WOUND?

Cicatization of wounds.—The period of time at which a particular wound was inflicted, may become a medicolegal question, both in relation to the living and dead. The identity of a person, and the correctness of a statement made by an accused party, may be sometimes determined by an examination of a wound or its cicatrix. So, if a dead body be found with marks of violence upon it, and evidence adduced that the deceased was maltreated at some particular period before his death, it will be necessary for a practitioner to state whether, from the appearance of the injuries, they could or could not have been inflicted at or about the time indicated. A case was tried at the Taunton Spring Assizes, 1841 (The Queen against Raynor), wherein evidence of this kind served to disprove the statement made by the
CICATRIZATION OF WOUNDS.

accused. He was charged with maliciously cutting and wound-
ing the prosecutrix. There was a cut upon his thumb, which he
accounted for by saying it was from an accident that had
occurred three weeks before. The medical witness declared, on
examining it, that it could not have been inflicted more than two
or three days, which brought the period of its infliction to about
the time of the murderous assault. This and other circumstan-
tes led to his conviction.

An incised wound inflicted on the living body, gradually heals
by adhesion when no circumstances interfere to prevent the
union of the edges. For eight or ten hours the edges remain
bloody,—they then begin to swell, showing the access of inflam-
mation. If the parts be not kept well in contact, a secretion of
a serous liquid is poured out for about thirty-six or forty-eight
hours. On the third day this secretion acquires a purulent
character. On the fourth and fifth days, suppuration is fully
established, and it lasts five, six, or eight days. A fibrous layer,
which is at first soft and easily broken down, then makes its
appearance between the edges:—this causes them gradually to
unite, and thus is produced what is termed a cicatrix. Cicatri-
ization is complete about the twelfth or fifteenth day, when the
wound is simple, of little depth, and only affecting parts
endowed with great vitality. The length of time required for
these changes to ensue will depend—1. On the situation of the
wound;—wounds on the lower extremities are longer in healing
than those on the upper part of the body. If a wound be si-
tuated near a joint, so that the edges are continually separated
by the motion of the parts, cicatization is retarded. 2. On the
extent. Wounds involving many and different structures are
longer in healing than those simply affecting skin and muscles.
3. On the age and health of the wounded party;—the process of
cicatization is slow in those who are diseased and infirm. In
an incised wound, the cicatrix is generally straight and regular;
but it is semilunar if the cut be oblique. It is soft, red, and
tender if cicatization be recent: it is hard, white, and firm if of
long standing. On compressing the skin around an old cicatrix,
its situation and form are well marked by the blood not readily
entering into it on removing the pressure. It has been said that
the cicatrices of incised wounds are rectilinear, but this is not
always the case; in general, they are more or less elliptical, being
wider in the centre than at the two ends,—this appears to be due
principally to the elasticity of the skin and the convexity of the
subjacent parts: thus it is well known that in every wound on
the living body the edges are much separated in the centre, and
this physical condition influences the process of cicatization.
When the wound is in a hollow surface, or over a part where the
skin is not stretched, as in the armpit or groin, then the cicatrix
may be rectilinear, or of equal width throughout. If there
were any loss of substance in an incised wound, or if the wound were lacerated or contused, the cicatrix would be irregular, and the healing would proceed by granulation. The process might then occupy five, six, or eight weeks, according to circumstances. When healed, the cicatrix would be white, and if there had been a loss of substance it would have a puckered appearance; the surface of the skin would be uneven. (See an essay on this subject by Dr. Krugelstein, Henke's Zeitschrift der S. A. 1844, ii. 75.)

Is a cicatrix always a consequence of a wound?—If we here use the term wound as implying a breach of continuity affecting the layers of the true skin, a cicatrix is always produced in the process of healing. In even cuts made by a very sharp instrument, especially if they be in the direction of the fibres of subjacent muscles, and the parts be kept in close apposition, the cicatrices are even, linear, and sometimes so small as to be scarcely perceptible. If, besides, the skin be white, they may be easily overlooked. Wounds of this kind are not, however, commonly the subject of medico-legal inquiry. If, on examining a part, where at some previous time a stab or a cut is alleged to have been inflicted, we find no mark or cicatrix, it is fair to assume that the allegation is false, and that no wound has been inflicted, making due allowance for the fact that mere abrasions of the cuticle, or very slight punctures and incisions, often heal without leaving any well-marked cicatrices.

Is a cicatrix, when once formed, ever removed, or so altered by time as to be no longer recognisable?—This is rather an important question, which sometimes presents itself to a medical jurist both in civil and criminal proceedings. They who have given close attention to this subject, agree in considering that cicatrices, when they are once so produced in the cutis as to be easily perceptible, are indelible,—they undergo no sensible alteration in their form or other external characters. The tissue of which a cicatrix is formed, is different from that of the skin; it is harder and less vascular, and is destitute of rete mucosum, so that its whiteness, which is particularly remarkable on the cicatrized skin of a negro, is retained through life. If any cicatrices were easily obliterated, it would be those which are even and regular,—the results of incised wounds by sharp instruments; but I have observed that cicatrices of this kind have certainly retained their characters unchanged in one instance for twenty, and in another for twenty-five years. According to the observations of Dupuytren and Delpetch, the substance of a cicatrix is not converted into true skin—it never acquires a rete mucosum. In the cicatrices of lacerated and contused wounds, the form of the weapon with which the wound was inflicted is sometimes indicated. It is not, however, easy to distinguish the cicatrix of a stab from that produced by a pistol-bullet fired
from a distance. In both cases the edges may be rounded and irregular, and the cicatrix puckered, unless the stab had been produced by a broad-bladed weapon.

Characters of cicatrices.—It is important to observe that all cicatrices are of smaller size than the original wound; for there is a contraction of the skin during the process of healing. This is especially observed with regard to the cicatrix of a stab, which is frequently of a triangular form. A recent wound, as it has been elsewhere stated, is apparently smaller than the weapon; and the resulting cicatrix is always smaller than the wound. Hence it is difficult to judge of the size of the weapon from an examination of the cicatrix. In gun-shot wounds, if the projectile has been fired from a distance, the cicatrix is of smaller diameter than the ball:—it represents a disk depressed in the centre, and attached to the parts beneath; while the skin is in a state of tension from the centre to the circumference. If the bullet has been fired near to the body, the cicatrix is large, deep, and very irregular. If the projectile has made two apertures, the aperture of exit is known by the greater size and irregularity of the cicatrix. (See Ed. Monthly Journal, 1854, vol. x. p. 370.) As the age of a cicatrix increases, it becomes smaller, thicker, more shining, fainter in colour and less sensitive.

Cicatrices from disease or wounds.—In certain cases a question may arise whether the cicatrix on a person has resulted from a wound or from loss of substance through disease, e.g. scrofulous ulceration. In the case of Smyth v. Smyth (Gloucester Summer Assizes, 1853), the plaintiff claimed to be the rightful heir to certain estates occupied by the defendants. He based his claim upon some deeds (alleged by the defendants to have been forged), in which it was stated, that the lost heir to these estates would be known by certain marks on his right hand and wrist, suggested to have been received at the time of his birth, in 1797, by reason of his having been brought into the world by instruments. It was one of the curious features of this extraordinary case of imposture, that no medical opinion was taken or required by the claimant on the probable nature and origin of these marks. When requested to show his hand to the jury, the mark had the appearance of a puckered cicatrix, from a scrofulous ulcer near the wrist. Similar marks from scrofulous sores were seen upon his neck. His statements regarding himself, and the circumstances on which he based his claim, were so improbable and contradictory, that the case speedily broke down. A question of this kind may occasionally present some difficulty, but a close examination of the cicatrix, with a consideration of the statement of the person as to its mode of production, will generally enable a practitioner to arrive at a satisfactory conclusion respecting its origin. Scrofulous ulcers are generally observed to leave irregular and furrowed cicatrices, with smooth depres-
sions, surrounded by hard and uneven margins. According to Schneider, the *scorbutic* cicatrix is dark, bluish-red in colour, soft to the touch, somewhat raised and rather painful: in the course of time it becomes flatter, of a reddish-brown colour, approaching to green (?) in the centre, and very thin and easily injured. *Syphilitic* cicatrices are characterised by great loss of substance: they approximate the margins of the deep ulcers before their granulations have had time to reach the surface. *Glandular* cicatrices are irregularly tumified, generally deep, hardened, and of a reddish-brown colour. These varieties cannot easily be mistaken for the cicatrices of wounds.

*When was the wound inflicted?*—When an individual is not seen until after death, and there are recent wounds on his body, a medical jurist may be required to state at what period they were probably inflicted. It may be taken as a general rule that there are no appreciable changes in any wound until eight, ten, or twelve hours have elapsed from the time of its infliction; then we have the various phenomena of inflammation, followed by adhesion, suppuration, or gangrene, during any of which stages the wounded person may die. Some remarks have already been made on the time at which adhesion and suppuration are established in wounds; and with respect to gangrene it may be observed, that the deceased must have survived at least fifty hours, in order that this process should be set up: in old persons it may take place earlier.

In examining a dead body, we must take care not to confound the effects of putrefaction in a wound with those of gangrene. Putrefaction always commences sooner in parts which are wounded than in those which are uninjured; but the general appearance of a body will show whether the changes in the wound are or are not due to putrefaction. The collapse of the eye will indicate the existence of this process; but the presence of warmth or rigidity of the members will show that death may have been too recent for putrefaction to have become established. The time at which a severe *contusion* has been produced, may be commonly determined by noting the changes of colour which take place around it. It is rarely until after the lapse of twenty-four or thirty-six hours that these changes of colour appear. (See *Ecchymosis*, ante, p. 240.) The livid circumference passes into a green circle, which is gradually diffused into a wide straw-yellow band, bounding the ecchymosis on every side, if it be in a free or loose part of the skin. In four, five, or six days, the dark livid colour slowly disappears from the circumference to the centre, while the coloured bands spread more widely around. A central dark spot may be perceived after ten days or a fortnight, and in an extensive ecchymosis it is some weeks before all traces of colour are lost. The rapidity of these changes will be *modified by circumstances* elsewhere stated. Observations of
this kind often lead to useful results when proper caution has been taken. The appearances presented by a contusion inflicted recently before death, and of another inflicted some days before, are of course different; and by an appreciation of this difference, a person charged with murder may or may not be connected with one or the other period of infliction, or with both. In a case of alleged manslaughter, in which I was consulted some years since, there were found on the person of the deceased, the wife of a mechanic, the marks of severe bruises; some of them, in the immediate neighbourhood of each other, had the rings of colour peculiar to a disappearing ecchymosis, while others had not. The man alleged in his defence that he had only struck his wife once, a few hours before her death, whereas the above medical facts proved not only that the deceased had been struck more than once, but that some of the blows must have been inflicted probably several days before her death. These inferences were corroborated by the evidence of an apprentice who had witnessed the assaults.

Such is an outline of the facts which may occasionally enable us to say how long before death particular injuries have been received; or to assign a probable period for their infliction on the living. By their aid we may have it in our power to determine whether two wounds found on a dead body were or were not inflicted at or about the same time. The law in these cases seldom requires a precise medical opinion; indeed it would be scarcely possible to give this under any circumstances. If a medical witness can only state about what time the injury was inflicted, circumstantial evidence will make up for the want of great medical precision or accuracy on the point.

How long did the deceased survive?—This question, it will be perceived, is indirectly connected with the preceding, although sometimes put with an entirely different object. Supposing the wound not to have been such as to prove rapidly fatal, the length of time which a person has survived its infliction may be determined by noting whether it has undergone any changes towards healing, and in what degree. As a wound remains in the same state for about eight or ten hours after its production, it is not possible to say within this period how long the person may have survived. Then it has been supposed that a medical opinion might be formed from the nature of the injury, and the parts which it has involved. Thus, a wound may have involved large blood-vessels, or organs important to life: in this case it is pretty certain that the individual must have died speedily. Let us, however, bear in mind that these so-pronounced rapidly mortal wounds sometimes do not prove fatal until after the lapse of some hours or days—a fact which has been much overlooked by surgeons, although of considerable importance in relation to the medical jurisprudence of wounds.
CHAPTER XXXII.

Acts indicative of volition and locomotion. — In cases of death from wounds criminally inflicted, it is often a matter of serious inquiry, whether a person could have performed certain actions, or have moved after receiving an injury which is commonly regarded as necessarily mortal, and likely to destroy life speedily. In respect to wounds of a less grave description, if we except those affecting the members directly, which will be hereafter examined, the power of willing and moving in the person who has received them cannot be disputed. The best way of treating this subject will be, perhaps, to select a few cases of severe injuries to important parts or organs, which are usually considered to destroy life speedily. The question relative to the power of exercising volition and locomotion, has been chiefly confined to those cases in which there were injuries to the head, wounds of the heart, the large blood-vessels, the diaphragm, and bladder.

Injuries to the head not immediately fatal. — The following case occurred a few years since in the Norfolk and Norwich Hospital:—A boy, owing to the bursting of a gun, had the breech-pin lodged in his forehead. He got out of the cart, in which he had been brought four or five miles, and walked into the hospital without assistance. The pin was firmly impacted in the frontal bone, about the situation of the longitudinal sinus. On its removal, a portion of brain came away with several pieces of bone, and the aperture in the cranium was nearly an inch in diameter. Symptoms of coma then came on, and the boy died in forty-eight hours. The brain was found to be considerably injured. (Med. Gaz. xviii. p. 458.) Mr. Watson mentions a similar case. During a quarrel between father and son, the latter threw a poker at the former with such violence that the head of the poker stuck fast in his forehead, and was with some difficulty withdrawn. The father asked those who were near him to withdraw the weapon, and he was afterwards able to walk to the infirmary. He died from inflammation of the brain. (On Homicide, p. 62.) A case occurred to Dr. Wallace, of Dublin, in which a man fell from a scaffold on the summit of his head. He was stunned by the fall, but on reaching the hospital, dismounted from the cart which conveyed him, and walked upstairs with very little assistance. He died in three days, but he remained perfectly rational, and was enabled to get up and go to the water-closet.
the day before his death. On inspection, there was only a slight abrasion on the summit of the head, but the skull was found split into two nearly equal halves from the frontal bone backwards, and the longitudinal sinus was laid open throughout. In the hemispheres of the brain there was a large quantity of effused blood in a semi-coagulated state; and more than two ounces were found at the base of the skull. (Lancet, April 1836.) Supposing this person to have been found dead with such extensive injuries, the medical opinion would probably have been that he was not likely to have lived or moved afterwards; and yet the power of volition and locomotion remained with him for two entire days!

It is easy to conceive many cases in which a question of this kind will be of material importance. For instance, a man may fall from a height, and produce a severe compound fracture of the skull. He may, nevertheless, be able to rise and walk some distance before he falls dead. (See case, ante, p. 259.) Under these circumstances there might be a strong disposition to assert that the deceased must have been murdered,—the injuries being such that they could not have been produced by himself, there being at the same time no weapon near, and no height from which it might be supposed he had fallen. The discovery, after death, of severe injury to the head, with great effusion of blood on the brain must not lead a surgeon to suppose that the person who sustained the violence had been immediately incapacitated. In the case of Reg. v. Mihler and others (Derby Summer Assizes, 1854), in which a Mr. Bagshawe had been assaulted by the prisoners and had died from the injuries sustained, it was proved that the temporal bone was beaten in, the base of the skull fractured, and there was a large coagulum of blood effused on the left side of the brain, which by its pressure had flattened this organ. Notwithstanding these injuries, deceased walked a considerable distance, and he survived about twelve hours. There is reason to believe that in this and other cases of a similar kind the large effusion of blood was an after-result.

Wounds of the heart not immediately fatal.—Wounds of the heart were formerly considered to be immediately fatal to life: but this only applies to those wounds by which the cavities of the organ are extensively laid open. Persons who have sustained wounds of the heart have frequently lived sufficiently long to exercise the power of volition and locomotion. Mr. Watson met with a case in which a man who had been stabbed in the right ventricle ran eighteen yards after having received the wound. He then fell, but was not again able to rise; he died in six hours. On dissection, it was found that a punctured wound had extended into the right ventricle in an obliquely transverse direction, dividing in its course the coronary artery. The pericardium was nearly filled with blood, and about four pounds were effused on the left side of the chest. (On Homicide, p. 98.)
One of the most remarkable cases of the preservation of volition and locomotion after a severe wound of the heart will be found reported in the Medical Gazette (xiv. p. 334). In this case the patient, a boy, survived five weeks, and employed himself during that period in various occupations. After death a mass of wood was found lodged in the substance of the heart. Had this boy been found dead with such an injury, it is most probable the opinion would have been that his death was instantaneous. Dr. Darling, of New York, has communicated to me the particulars of a case which occurred in February 1855, in which a man survived for a period of eleven days a bullet-wound of the heart. Soon after receiving the wound he became senseless, cold, and pulseless, and remained in this collapsed state for four hours. He then rallied, but died on the eleventh day. On inspection, there was no effusion of blood: the pericardium was much distended by serum, the result of inflammation. A bullet, one-third of an inch in diameter, was found lodged in the septum or fleshy partition between the right and left ventricles, about midway between the apex of the heart and base of the ventricles. There was no communication with the cavities—the wound had entirely cicatrized; and inflammation of the pericardium was obviously the cause of death.

A case of some interest in reference to the power of surviving a severe wound of the cavities of the heart, occurred at Guy’s Hospital, in February 1854, for the particulars of which I am indebted to Mr. Callaway. An Italian, 36, discharged a brace of pistols into his chest on the left side. The man was brought to the hospital, was able to converse on his condition, and lived one hour and fifteen minutes after the infliction of the wound. After death it was found that one bullet had perforated the pericardium, entered the right ventricle, and, after traversing the septum of the ventricles, made its exit from the heart at the junction of the left auricle with the ventricle. It traversed the upper lobe of the left lung, and was found fixed in one of the dorsal vertebrae. The second bullet perforated the left ventricle, and then traversed the left lung. This wound was of such a nature, that at every contraction of the ventricle, the opening must have been closed so as to arrest the flow of blood. This man, owing to severe suffering, rolled about the floor, and was with difficulty kept quiet. It will be seen that in this case there were bullet-wounds traversing completely the cavities of the heart; yet the man could talk and exert himself, and he actually survived their infliction one hour and a quarter. Had the body been found dead in a suspicious locality, the discovery of such wounds in the ventricles of the heart might probably have led to a medical opinion that the death of the man must have been instantaneous! In these cases, little or no blood probably escapes from the heart in the first instance, but it may afterwards continue to ooze
LARGE ARTERIES NOT IMMEDIATELY FATAL. 347

gently, or suddenly burst out in fatal quantity. It must not, therefore, be supposed, when a person is found dead with a wound of the heart, attended with abundant hemorrhage, either that the flow of blood took place in an instant, or that the person died immediately and was utterly incapable of exercising any voluntary power. Only one circumstance will justify a supposition of this kind,—namely, where the cavities of the organ, especially the auricles, are largely laid open.

Wounds of the carotid arteries not immediately fatal. — Questions relative to the power of locomotion perhaps more frequently occur with respect to wounds of the great blood-vessels of the neck than of the heart,—suicide and murder being more commonly perpetrated by the infliction of such wounds. There are several cases on record which show that wounds involving the common carotid artery and its branches, as well as the internal jugular vein, do not prevent a person from exercising voluntary power, and running a certain distance. In one of these (Rex v. Danko, Warwick Lent Assizes, 1832) it was proved that the deceased had died from a wound in the throat inflicted by the prisoner, which divided the trunk of the carotid artery, the principal branches of the external carotid and the jugular veins. The evidence rendered it probable, if not certain, that after the infliction of this wound, the deceased had been able to run twenty-three yards and to get over a gate,—the time required for the performance of such acts being from fifteen to twenty seconds. Most medical witnesses would have probably given an opinion that the deceased could not have moved from the spot where such a wound had been inflicted; but it was clear that she had gone this distance—there was no dragging of the body, and no motive for its being dragged by the prisoner and exposed in an open road, where it was found. (Medical Gazette, vol. x. p. 183.) Such cases as these show the necessity of caution in giving an opinion respecting immediate death from wounds.

There is one circumstance which requires notice in relation to severe wounds in the throat—namely, that although the individual may have the power of locomotion, he may not be able to use his voice so as to call for assistance. It sometimes excites surprise at an inquest, how a murder may in this way be committed without persons in an adjoining room hearing any noise; but the fact is well known medically, that when the trachea is divided, as it generally is on these occasions, the voice is lost.

Ruptures of the diaphragm. — A rupture of the diaphragm has been considered sufficient to deprive a person of the power of locomotion; but there appears to be no good ground for this opinion. The general effect of such an injury may be to incapacitate a person; but the question is put to a medical jurist as to the possibility of a wounded person being able to move on
walk after the injury,—and this, as a general rule, must be admitted.

Ruptures of the liver, unless attended at once with great loss of blood, do not prevent a person from exercising his muscular power. In the case of Gordon (Glasgow Spring Circuit, 1856), it was proved that the deceased had died from ruptured liver; but after sustaining the violence, he had been able to reach home on foot, although with some difficulty.

Ruptures of the bladder.—In ruptures of the bladder, attended with extravasation of urine, the same question as to the existence of a power of locomotion has arisen. By the answer to this we may sometimes determine whether the rupture was the result of homicide or accident. The following cases will show that this power does exist in some instances, although the general result is perhaps to incapacitate the individual from moving:— A man, aged thirty-one, while intoxicated, received a blow on the lower part of his abdomen. He was sobered by the accident, and walked home, a distance of a quarter of a mile, although suffering severe pain. When seen in the evening, twelve ounces of bloody urine were drawn off by a catheter, and he complained of having felt cold immediately after he had received the blow. He died four days after the accident. On inspection, there was no mark of bruise or ecchymosis on any part of the abdomen. The bladder was ruptured in its upper and posterior portion for about an inch. (Lancet, May 14, 1842.) The second case was related to me by a pupil. A gentleman who had been compelled to retain his urine, fell accidentally, in descending a staircase, with the lower part of his abdomen against the edge of one of the steps. The sense of fulness in his bladder immediately ceased, and he walked to a friend's house to dinner. The nature of the accident was mentioned to a surgeon there present, who immediately suspected that the bladder must have been ruptured. The case terminated fatally in twenty-four hours. A case is reported by Mr. Hird, in which a man walked a distance of two miles after having sustained a rupture of the bladder; and in another which occurred in January, 1852, communicated to me by Mr. Rake, the man, who sustained the injury in a scuffle, was able to walk a mile between two and three hours after the occurrence. (See also Lancet, Oct. 31, 1846, p. 480.) Thus, then, from these various instances, it is evident that locomotion and muscular exertion may take place after an accident of this description.

Summary.—Under survivorship from many severe accidents or personal injuries, this power of moving, if not exerted to a large extent, may take place in a small degree; and this may become occasionally an important question in legal medicine. Thus it must not be lost sight of, when we are drawing inferences as to the relative position of a murderer and a murdered person from the situation in which the body of the deceased is found. A
dead man, with a mortal injury to the head or heart, may be found lying on his face, when he actually fell upon his back, but still had had sufficient power to turn over before death; or he may have fallen on his face, and have afterwards moved, so that the body may be found lying on the back. A slight motion of this kind is very easily executed; it does not always depend on volition. Individuals suffering from severe concussion have been frequently known to perform acts unconsciously and automatically. The cases above related may perhaps be considered rare, and as exceptions to the general rule. The medical jurist must bear in mind, however, that he is not required to state in how many, out of a given number of individuals similarly wounded, this power of performing acts indicative of volition and locomotion may remain, but simply whether the performance of these acts be or be not possible. It is on this point only that the law requires information. The hypothesis of guilt, when we are compelled to judge from circumstances in an unknown case, can only be received by the exclusion of every other possible explanation of the facts. On surgical prognosis or treatment, such cases, from their rare occurrence, may have little influence; but in legal medicine the question is widely different. Medical facts, however rare, here admit of a very important and unexpected application.

Struggling after severe wounds.—Although, in cases of severe wounds, we may allow that persons may survive for a sufficiently long period to perform various acts of volition and locomotion, yet the presence of a mortal wound, especially when of a nature to be accompanied by a great loss of blood, must prevent all struggling or violent exertion on the part of the wounded person; such exertion we must consider to be quite incompatible with the condition of the wounded person. A medical jurist may thus have it in his power to determine whether a mortal wound found on the deceased has been inflicted for the purpose of murder or in self-defence, as the following case, reported by Mr. Watson, will show:—A man was tried at the Lancaster Assizes in 1834, for the murder of a woman at Liverpool, by stabbing her in the chest. Prisoner and the deceased, with two other females, were quarrelling in the passage of a house. A struggle ensued between the prisoner and deceased, which one of the witnesses said lasted for ten minutes. When the prisoner had reached the door, he pulled out a knife and stabbed the deceased in the chest. She fell, and died almost immediately. The prisoner alleged that he was attacked by several persons, and that he stabbed the woman in self-defence. The judge said, if the blow had been struck with premeditation before the struggle, the crime would be murder,—if during the struggle, it would be manslaughter. The medical evidence showed that the blow could not have been struck before the struggle, because it was
of a speedily mortal nature; and the deceased would not then have been able, as it was deposed to by the witnesses, to struggle and exert her strength with the prisoner for ten minutes afterwards. This being the case, it followed that in all medical probability the deceased had received the wound towards the conclusion of the quarrel; and therefore it might have been inflicted while the prisoner was attempting to defend himself. The jury returned a verdict of manslaughter.

A case involving this medico-legal question was tried at the Gloucester Lent Assizes, 1849 (Reg. v. Hobbs). The prisoner was indicted for the wilful murder of a man with whom he had been drinking and quarrelling. It appears that in the early part of the quarrel the deceased threw the prisoner down and struck him unfairly. The deceased was told by the landlord of the inn to go home. He replied “Very well,” and then leaving the prisoner, went through the entrance-arch of the inn up the yard, which was his usual way of going home. About seven minutes afterwards the prisoner, who had complained to the landlord of the maltreatment which he had undergone, returned into the inn-yard, and was seen on entering it to pull down his waistcoat and button his coat. A witness advised him to go home, and he left the spot. A short time afterwards the deceased was found at the back of the yard, lying on his face, and quite dead. On examining the body it was ascertained that the deceased had been stabbed in two places, one of the stabs having penetrated the ventricle of the heart. On apprehending the prisoner, a large clasp knife was found in his pocket stained with blood. The prisoner admitted that he had stabbed the deceased, but said it was during the quarrel, and that he used the knife in self-defence while they had him on the ground. This was the defence. For the prosecution it was contended that the deceased had been stabbed by the prisoner subsequently to the quarrel—that he had gone through the gate into the yard to meet the deceased, had there stabbed him, and had caused his instant death. The medical witness who was called, stated at first, that from such a wound death must have been instantaneous. In cross-examination, however, he admitted that the deceased might have lived some time after he had been stabbed; and on this evidence the prisoner was convicted of manslaughter, and sentenced to six months’ imprisonment.

The medical facts of this case are rather imperfectly reported; hence it is difficult to give a decided opinion respecting the time at which the deceased was stabbed in the heart. It is true that the Duc de Berry survived a punctured wound of one of the ventricles for the long period of eight hours; but every case must be judged by the special circumstances accompanying it. The size of the stab in the ventricle is not stated; nor is it in evidence whether any blood was found on the spot where the
AFTER WOUNDS OF THE HEAD.

351

deceased was struggling with the prisoner. That the deceased should have struggled with the prisoner for one minute after being stabbed in the ventricle of the heart is contrary to all medical probability. It is also irreconcilable with the existence of such a wound, that the deceased should have spoken to the landlord,—that he should not have called the attention of the latter to the fact of his having been stabbed by the prisoner while struggling with him,—that he should have been stabbed in the heart without knowing it, or without being aware of his condition,—that he should have been able thereafter to walk away through the inn-yard to the house, and survive seven minutes while thus walking; and yet all these circumstances must have happened, in order that the defence, and the verdict based upon it, should be true. Taking the facts as reported, it is, it appears to me, impossible to arrive at any other conclusion than that the deceased was stabbed by the prisoner subsequently to the quarrel, while he was walking through the inn-yard. The only circumstances for the defence were the prisoner’s statement, and that, in some rare cases, certain wounds of the heart do not prove immediately fatal.

The case of Reg. v. E. M. Brown (Dorchester Summer Assizes, 1856) presents some points of interest in reference to the question under consideration. The prisoner was charged with the murder of her husband by blows on the head while in her room. Her statement was that the violence on the head was produced by the kick of a horse. The medical evidence showed that the bones of the nose were broken; there was a triangular wound exposing the bone above the left eyebrow, another triangular wound exposing the bone at the top of the head, and a third wound at the back of the head. The left ear was perforated; and behind it was a long wound divided into two. The frontal bone was fractured from the orbit, through the parietal into the occipital bone. Seven pieces of bone, varying in size from half an inch to three inches, had been driven into the brain, and a large quantity of blood was effused. The prisoner’s account was that she found her husband thus wounded and bleeding outside the house, that she dragged his body into an inner room, and, further, that though thus wounded, he held her tightly by the clothes for two hours afterward. It was proved that there was no blood over the front of the person or dress of deceased, and that there was no blood in the passage or in any part of the house, except in the room where the body was found lying. Further, the injuries were not such as a kick from a horse would explain; and the medical witness properly stated that a man thus injured could not have held the prisoner by the clothes for two hours, so as to prevent her from seeking earlier for assistance. The facts showed that deceased had been killed by blows where his body was found; and the prisoner was convicted.

OF THE FACE—INJURIES TO THE SPINE—FRACTURES OF THE
VERTEBRAE—DEATH FROM INJURIES TO THE SPINE AND SPINAL
MARROW.

The danger of wounds, and their influence in causing death, are
the two principal points to which the attention of a medical
jurist must be directed.

WOUNDS OF THE HEAD.

Incised wounds, affecting the scalp, rarely produce any serious
effects; but this will, of course, depend on their extent. When
the wound is contused, and accompanied by much laceration of
the skin, it is highly dangerous, in consequence of the ten-
dency which the inflammatory process has to assume an ery-
sipelatous character. The results of these wounds are, however,
often such as to set all general rules of prognosis at defiance.
Slight punctured wounds of the scalp will sometimes terminate
fattally, in consequence of inflammation being set up in the ten-
dinous structures, followed by extensive suppuration beneath,
while, on the other hand, a man will recover from a lacerated
wound by which the greater part of the skin may have been
stripped from the bone. There are two sources of danger in
wounds of the scalp:—1. The access of erysipelatous inflam-
maion. 2. Inflammation of the occipito-frontalis tendon, followed
or not by the process of suppuration. Either of these secondary
effects may operate fatally in slight or severe wounds. Neither
can be regarded in the light of an unusual consequence of a se-
vere wound of the scalp: but when one or the other follows a very
slight injury, there is reason to suspect that the patient may have
been constitutionally predisposed; and if fatal effects ensue, the
influence of the predisposition might be considered as a mitiga-
tory circumstance. Bad treatment may likewise lead to a fatal
result from a wound not regarded as serious in the first instance;
but the question, how far the responsibility of the aggressor
would be affected by a circumstance of this nature, has been
considered in another place (ante, p. 329). Wounds of the head
are dangerous in proportion as they affect the brain; and it is
rare that a severe contused wound is unaccompanied by some
injury to this organ. There is, however, a difficulty which a
practitioner has here to contend with—namely, that it is scarcely possible to predict, from the external appearance of a wound, the degree of mischief which has been produced internally. These injuries, as it is well known, are very capricious in their after-effects; the slightest contusions may be attended with fatal consequences, while fractures, accompanied by great depression of bone, and an absolute loss of substance of the brain, are sometimes followed by perfect recovery. (Cormack’s Jour. Sept. 1845, p. 653; Med. Gaz. xxxix. p. 40; and Phil. Med. Exam. Nov. 1845, p. 696.)

Another difficulty in the way of forming a correct prognosis consists in the fact, that a person may recover from the first effects of an injury, but after a short time he will suddenly die; and on examination of the body, the greater part of the brain will be found destroyed by the suppurative process, although no symptoms of mischief may have manifested themselves until within a few hours of death.

Concussion.—The common effect of a violent contusion on the head is to produce concussion or extravasation of blood, or both. In concussion, the symptoms come on at once, and the patient, if severely affected, sometimes dies without any tendency to reaction manifesting itself. But the period at which death takes place is liable to vary: a man may die on the spot, or he may linger in a state of insensibility several days, and in either case, after death, no particular morbid change may be discovered; there may be the mark of a slight bruise. In the case of Reg. v. Burgess (Liverpool Lent Assizes, 1845), the deceased, who was the subject of violence, fell and died on the spot, and there was no lesion externally or internally. The state of insensibility observed in concussion is sometimes only apparent. Mr. Guthrie relates the following singular case:—A gentleman who had met with an accident on board of a vessel at sea, while lying apparently deprived of sense and motion, heard a discussion between a relative and another person, who supposed he was dying, as to the mode in which they would dispose of his body, and he was conscious of his utter inability to make any movement indicating that he was alive and understood their conversation. Fortunately they resolved to convey him to the port to which the vessel was bound.

Inflammation may follow the primary shock from concussion, —suppuration will take place, and the patient may die after the lapse of some weeks, or even months. It is important, in a medico-legal point of view, to notice that an individual may move about and occupy himself, while apparently convalescent, for a week or ten days after recovery from the first shock, and then suddenly be seized with fatal symptoms, and die. This apparent recovery leads to the common supposition, that death must have been produced by some intervening cause, and not by the original violence to the head—a point generally urged in the
defence of such cases. When the inflammation that follows concussion is of a chronic character, the person may suffer from pain in the head and vomiting, and die after the lapse of weeks, months, or even years. A case is mentioned by Hoffbauer, in which a person died from the effects of concussion of the brain, as the result of an injury received eleven years before. (Ueber die Kopfverletzungen, 1842, 57.) Concussion may sometimes take place as a consequence of a violent fall on the feet, in which case the head receives a shock through the medium of the spinal column. The skull may be extensively fractured, and the brain may be even shattered by such a fall. This was the cause of death in the case of the late Duke of Orleans. (Med. Gaz. xxxvi, p. 368.)

In the case of Allen v. the Chester Railway Company (Court of Common Pleas, Feb. 1857), the plaintiff claimed damages for injury caused by a railway collision. The evidence showed that the plaintiff received a blow on the head. There were no immediate symptoms; but in two days the plaintiff suffered from lightness of the head and other symptoms, attributed by his medical attendant to concussion of the brain, as a result of the accident. Subsequently there were symptoms of injury to the spine. There was pain in the course of the spine, partial paralysis of the bladder, rectum, and lower extremities, with loss of memory. The medical witnesses for the plaintiff, including Mr. Solly and Mr. Wells, attributed these symptoms to a blow received by plaintiff at the base of the skull. The defendants contended that if these were the results of concussion of the brain, they ought to have manifested themselves immediately on the occurrence of the accident; and this view was to some extent supported by the evidence of Mr. Lawrence, Mr. Arnott, Mr. Ferguson, and others. In substance, however, the medical evidence on the two sides was not conflicting. Concussion of the brain, as it is ordinarily known to surgeons, is generally attended with immediate symptoms; but the witnesses for the defence properly admitted that "a concussion of the brain (and spine?), attended with apparently slight symptoms at first, might, under peculiar circumstances, be followed by serious symptoms." As no other cause could be assigned for the symptoms, this was practically admitting that the plaintiff had suffered from the injury, the degree being simply a question for the jury. They very properly returned a verdict for the plaintiff.

Concussion distinguished from intoxication.—The symptoms under which a wounded person is labouring may be sometimes attributed to intoxication, and a medical witness may be asked what difference exists between this state and that of concussion. The history of the case will, in general, suffice to establish a distinction, but this cannot always be obtained. It is commonly said that the odour of the breath will detect intoxication; but it is obvious that a man may meet with concussion after having
drunk liquor insufficient to cause intoxication, or concussion might take place while he is intoxicated,—a combination which frequently occurs. Under such circumstances we must wait for time to develop the real nature of the case; but concussion may be so slight as sometimes closely to resemble intoxication; and in the absence of all marks of violence to the head, and in the existence of a spirituous odour in the breath, the medical examiner might be easily deceived. If there be no perceptible odour in the breath, the presumption is, that the symptoms are not due to intoxication. On the other hand, intoxication may be so great as to give rise to the apprehension of fatal consequences, and the co-existence of a mark of violence on the head might lead to error in the formation of an opinion. What is the line of conduct to be pursued on such occasions? The examiner should weigh all the circumstances, and if there be one cause for the symptoms more probable than another, he should adopt it:—if there be any doubt, this should be stated to the Court.

There is nothing in the state of the brain in a dead body, which will enable a practitioner to distinguish whether concussion or intoxication has been the cause of the symptoms. The vessels may be congested in both cases. The discovery of alcoholic liquid in the stomach, may lead to a presumption that deceased had been intoxicated, while marks of violence on the head may favour the view that he had suffered from concussion. When both conditions are found, the examination of the body cannot lead to a solution of the question. The answer must then depend on the special circumstances proved, and on the nature of the symptoms preceding death.

It is to be feared that medical witnesses are not sufficiently careful, on these occasions, in determining whether there are any signs of intoxication about an injured person. Subsequent proceedings may render this a material part of the inquiry. In November 1851, the house-surgeon of a London hospital was severely reprimanded by a magistrate, in consequence of an omission to inquire and satisfy himself whether, in addition to the results of violence, a policeman who was brought to the hospital was or was not intoxicated when admitted. The question was of importance; the injuries to the head might have arisen from a fall; and a drunken man might readily meet with such injuries from accident. A person was charged with an assault on the policeman, but upon very suspicious evidence; and, in fact, could intoxication have been proved or rendered probable, there would have been no ground for the charge. The medical man had already certified that the patient was not intoxicated, but when pressed in cross-examination, could not say whether he was or was not. The case was immediately dismissed. There can be no excuse for not making an inquiry into the precise condition of an injured person, and arriving at the best
judgment of which the case admits. A state of intoxication often renders it difficult to form an accurate opinion in cases of alleged criminal wounding. Some instructive cases in reference to this complication of wounds, have been published by M. Tardieu. (See Med. Gaz. xliv. p. 347.)

Extravasation or effusion of blood.—A blow on the head may destroy life by causing an effusion of blood on the surface or in the substance of the brain. In pugilistic combats, when a person is thus struck, he commonly falls, and death may take place in a few minutes. On inspection, blood may be found effused either at the base or in the ventricles of the brain, and the question may arise—Did the injury which caused death arise from a blow or a fall? Two cases of this description are reported by Dr. Wharrie. The men were knocked down by blows with the fist, and they were taken up dead. (Cormack's Monthly Jour. Feb. 1846, 117.) It is not easy to give an answer to this question, nor is its relevancy in a legal view apparent, for as it is presumed the blow was the cause of the fall, it is fair to infer that the assailant should be responsible for the effects of either or both. In a case of this kind (Reg. v. Williams, Denbigh Lent Assises, 1856), in which deceased had received a blow and sustained a fall, and his death was proved to have resulted from the violence, the judge directed the jury, if the death was caused by "the fighting," to return a verdict against the prisoner. They, however, persisted in returning a verdict of not guilty; assuming that the fatal injury was caused by the fall and not by the blow! A heavy blow on the head may cause fatal effusion of blood; but in these instances the effusion more commonly arises from the violent concussion which the injured person sustains by the fall. A medical witness will therefore in general be compelled to admit that the fatal effusion might have taken place either from a blow or a fall.

This subject has important applications in legal medicine, for this is one of the most common causes of death in injuries to the head, and there are generally many cases of this description tried at the assises. Effusion may occur from violence, with or without fracture, and it may take place without being accompanied by any external marks of injury to the head. In the case of the Queen v. Phelps and others (Gloucester Ass. 1841), it was proved that there was great effusion of blood, and even laceration of the brain, in the deceased, without any corresponding external injuries. (See also, at the same Assises, the case of the Queen v. Thomas.) The late Dr. Griffiths, the American editor of this work, mentions a case which was the subject of a trial at Massachusetts, in which a person received a blow from a small stone, and died in ten minutes. On examination there was no external bruise or fracture of the bones: the ventricles were filled with congealed blood, and all the vessels were gorged with blood. It is remarkable that the skull was in this instance un-
usually thin (p. 287, Amer. ed.). The chief source of the effusion in violence to the head arises from a rupture of the meningeal artery, and this may occur from the mere shock or concussion, with or without a fracture of its bony canal. The blood thus effused acts by compressing the brain; this compression does not always cause death unless the blood be in large quantity, or unless it be effused in or around the base of the brain (medulla oblongata). Thus the hemispheres will bear a degree of compression which, if it affected that portion of the base of the brain from which the spinal marrow proceeds, would instantly destroy life. The most fatal effusions, therefore, are those which take place in a fracture of the base of the skull, whereby one or both lateral sinuses are commonly ruptured. There may, however, be laceration of the brain, with effusion of blood to some extent at the base, and yet the person may survive some days. Dr. Patterson, of Edinburgh, communicated to me a case which occurred in February 1854, in which a woman survived severe injuries to the head, supposed to have been inflicted by her husband, for a period of twelve days. She was insensible during the whole of this time, but some of the external marks of violence had nearly disappeared, and others had undergone the usual changes in colour. A severe blow had obviously been inflicted on the summit of the head. On inspection after death it was found that there had been laceration of the brain by counter-stroke, and a large clot of blood was observed to occupy the lacerated part, extending over the surface of the base of the brain and into the ventricles. In this case, the woman survived a severe injury for an unusually long period. In the case of Cuming (Edinburgh, Dec. 1853), the deceased, the wife of the prisoner, died from laceration of the brain, on the 8th of Nov., produced by blows on the head, inflicted by the prisoner, on the 26th of Oct. The woman lay in a state of insensibility during the whole period of thirteen days.

In cases of injuries to the head proving fatal by effusion of blood on the brain, a person may recover from the first effects of the violence, and apparently be going on well, when he will suddenly become worse, and die. Effusion takes place slowly at first,—it may be arrested by the effects of stupor from concussion, by a portion of the blood coagulating around the ruptured orifices of the vessels, or by some other mechanical impediment to its escape; but after a longer or shorter period, especially if the person be excited or disturbed, the bleeding will recur, and destroy life by producing compression. How many hours or days, after an accident, are required in order that such an increased effusion should take place, it is impossible to say; but in severe cases, it is generally observed to follow the injury within a short time. Sir Astley Cooper relates the case of a gentleman who was thrown out of a chaise, and fell upon his head with such
violence as to stun him in the first instance. After a short time he recovered his senses, and felt so much better, that he entered the chaise again, and was driven to his father's house by a companion. He attempted to pass off the accident as of a trivial nature, but he soon began to feel heavy and drowsy, so that he was obliged to go to bed. His symptoms became more alarming, and he died in about an hour, as it afterwards appeared, from effusion of blood on the brain.

**Effusion of blood from disease or violence. Diagnosis.**—Blood may be found effused in various situations within the interior of the skull; and the cause of the effusion may be either disease or violence. The skill of a medical jurist is often required to determine which of these causes is the more probable, as where, for instance, a pugilist has died after having received severe injuries to the head, and his adversary is tried on a charge of manslaughter. On these occasions it is often urged in the defence, that the fatal bleeding might have arisen either from a diseased state of the vessels of the brain, or, if the evidence render it probable that the blow was the cause, that the effects of the blow were aggravated by a diseased state of the vessels, or by the excitement into which the deceased was thrown, either from the effects of intoxication or passion. When the brain is not lacerated by violence, the blood is effused either on the surface of the hemispheres, between the membranes, or at the base. When the effusion is caused by violence, the effused blood is not always found under the spot where the blow was inflicted, but often, by counter-stroke on the surface of the brain, directly opposite to it:—a case which a medical witness has frequently been required to explain on trials, and which depends on the same cause as fracture by counter-stroke, i.e. on a separation of parts (laceration of the brain, effusion of blood, or even fracture of the bones) at the point of the skull directly opposite to that which sustains the violence. Dr. Paterson's case above related (ante, p. 357) furnishes a good instance of extensive injury by counter-stroke. A severe blow had been inflicted on the summit of the head, as the mark was plainly visible, but the fatal injury was found in the base of the brain, i.e. on the part opposite to that which received the blow. Here the brain was lacerated and blood effused. Again, fracture of the base of the skull is frequently the result of severe violence applied to the summit. (See case by Dr. Haworth, Med. Gaz. xxxvi. p. 368.) Effusions of blood from a diseased state of the vessels more commonly take place in the substance of the brain, but they sometimes occur on the surface of the organ from mere excitement or over-exertion of the muscular powers. A diseased condition of the vessels, and probably softening of the substance of the brain, will in these cases be apparent on inspection.

A mere inspection of the body does not always lead to the
discovery of the cause of an effusion on the brain. The violence causing an effusion of blood may have been slight, and unless attention is particularly directed to the subject, it may be overlooked. In a case which proved fatal in a London hospital, in August 1857, there was no fracture of the skull, or external injury to account for effusion of blood on the brain. The brain was not injured, and in fact there was no apparent cause of death but the effusion, and this was somewhat precipitately assigned to disease. A certificate of death from “apoplexy” was given, and the deceased was buried. It subsequently transpired that she had been maltreated by her husband, and that the effusion of blood was owing to the maltreatment!

**Effusion of blood from excitement.**—When engaged in the investigation of a case of this kind, it is always a fair matter of inquiry whether the violence, upon the evidence, was not of itself sufficiently great to account for the effusion of blood without the supposition of coexisting disease or excitement. Admitting that the rupture of a blood-vessel, and the extensive effusion of blood on the brain, may take place from simple excitement and passion, yet this is an event comparatively rare, at least in the young and healthy, while nothing is more common than that these results should follow violent injuries to the head, whatever the age or condition of the person. A medical witness should remember that on these occasions, if he is unable to say positively whether the effusion was due to the excitement or the blows, he will satisfy the Court if he only state clearly that which is, in his own mind, the more probable cause of death; and by weighing all the circumstances of the case exactly beforehand, he will rarely fail to find that one cause was more probable than the other. Thus, if a man, excited by passion and intoxication, is struck on the head, and the blow is very slight—such as an unaffected person would probably have sustained without injury—yet in this case insensibility and death follow, and, on examination, a quantity of blood is found effused in the substance of the brain, can it be a matter of doubt with the practitioner that the effusion was chiefly due to the excitement under which the deceased was labouring? To take a converse instance: a man engaged in a personal conflict with another, is struck most violently on the head, or falls with great force on that part of the body: on inspection it is found that death has arisen from effusion of blood on the surface of the brain, and it would be no unexpected consequence of the violence inflicted that a similar appearance should be met with in an individual calm and unexcited:—Can the practitioner hesitate to say, under these circumstances, that the blow would satisfactorily account for the effusion, without reference to any coexisting causes of excitement? These may be allowed to have their influence, in giving an increased tendency to cerebral hemor-
rhage, or in aggravating the consequences of the blow, but no further.

Effusion of blood causing death after a long period of time. — Admitting that blood has been effused on the brain as a result of violence, the person injured may survive the effects for so long a period as to create a legal doubt whether death can be strictly assigned to the violence. In this respect the case of Reg. v. Sullivan (C.C.C. Sept. 1853) is of some interest. I am indebted to Drs. McWilliam and Stevens, who gave evidence at the trial, for the particulars of this case. Deceased, who had been previously a healthy man, was knocked down by the prisoner, and fell with his head upon the ground. He appeared as if he was stunned, and staggered in attempting to walk: he complained of pain in the head and general weakness. This was on the 11th April, 1853. Although he suffered from pain in the head, he had no medical advice until the 12th May, and had performed his duties as an officer of the Customs. After this he suffered from dimness of sight, and became delirious. On the 29th he came under the care of Dr. McWilliam. There were marks of bruises on the head,—there was impairment of vision, a faltering gait, and other symptoms indicative of pressure on the brain. He improved under treatment, but the symptoms returned in an aggravated form about the 12th June. He became insane, and was transferred to St. Luke's Hospital. Dr. Stevens, under whose care he was placed, stated that deceased had delusions, and was evidently suffering from pressure on the brain. He recovered so far that he was about to be discharged, when the symptoms of pressure became aggravated, and death took place on the 17th August, i.e., four months after the infliction of the violence. On inspection, a shot was found imbedded in the frontal bone, not penetrating the skull. A large clot of blood existed between the layers of the arachnoid membrane, occupying the whole surface of the left hemisphere. The clot had evidently been there for some time, because it was partially invested with a false membrane. No large vessel was ruptured; there had probably been an escape of blood at different times, and this would explain the intermittent nature of the symptoms. The clot amounted to at least two fluid ounces, and the surface of the brain had been obviously indented by its pressure. Another clot of old standing was found in the pons varolii. The witnesses concurred in attributing death to the effusion of blood on the brain, and the effusion to the violence inflicted by the prisoner, although it was admitted to be probable that some additional effusion had taken place just before the last fatal recurrence of symptoms. The prisoner was convicted of manslaughter. The fact that the deceased had been healthy previous to the violence, and that after this he had constantly suffered more or less from symptoms of pressure on the brain, fully justified the medical opinion in spite
of the protracted nature of the case. There was no other cause but the violence to account for the effusion and death.

WOUNDS OF THE FACE.

Wounds of the face are important on several accounts. When of any extent, they are usually followed by great deformity; and when they penetrate the cavities in which the organs of the senses are situated, they often prove fatal either by involving the brain and its membranes, or by giving rise to inflammation in this organ. Wounds of the eyebrows are not always of so simple a nature as might at first sight be supposed. Besides being attended by deformity when they heal, they are liable to give rise, during the process of healing, to serious disorders of the neighbouring parts. Amaurosis and neuralgia are recorded among the secondary and not unusual consequences of such wounds, when the supra-orbital nerve has become at all implicated. Under certain conditions of the system, there may be inflammation of the parts within the orbit, extending by contiguity to the membranes of the brain, and proving fatal by leading to the formation of matter within that organ. Amaurosis in the right eye has been known to occur from a contused wound, not of a very violent nature, to the right eyebrow. Dr. Wallace, of New York, has reported two cases of amaurosis following blows over the infra-orbital nerve. (Med. Gaz. xxxi. p. 931.) Wounds apparently confined to the external parts of the face, frequently conceal deep-seated mischief. A sharp instrument penetrating the eyelid, and passing upwards with any force, will produce fracture of the orbital plate of the frontal bone, which is known to be extremely thin, and even injure the brain beyond.

Wounds of the orbit.—Sir Astley Cooper relates, that a girl, while playing with a pair of scissors, accidentally fell, and the point of the scissors passed upwards under the upper eyelid. It was found difficult to extract them; the eye became inflamed, but for some days after the accident the child was in the habit of walking a considerable distance daily to receive medical advice. In about ten days she suffered violent pain, with symptoms of inflammation of the brain, under which she died. On inspecting the body, it was found that the orbital plate of the frontal bone had been fractured, the dura mater torn, and the anterior lobe of the brain lacerated. (For a similar case, see Med. Gaz. xli. p. 563.) In several instances in this country, trials for murder have taken place, in which death has been caused by a penetrating wound of the orbit, leading to fracture of the orbital plate and injuring the brain.

Wounds of the nose.—These wounds are, generally speaking, of a simple nature, rarely giving rise to serious symptoms; but they are almost always attended with great deformity. If the injury
be confounded and, at the same time, extensive, a loss of the faculty of smelling will probably result. A penetrating wound of the nose, produced by passing a sharp-pointed instrument up the nostril, may destroy life by perforating the cribriform plate of the ethmoid bone, and injuring the brain. Such a wound, it is obvious, might be produced without leaving any external marks of injury. Dr. Corkindale, of Glasgow, met with a case in which a man died in nine weeks from the effects of a wound of the nose, whereby the nasal bones were fractured. On inspection, there was copious inflammatory effusion at the surface of the brain, particularly at the part corresponding to the seat of the violence. An injury to the bones of the nose may prove fatal by giving rise to an attack of tetanus. A case of this kind has been elsewhere related (ante, p. 334).

Deformity as a consequence of wounds of the face.—Wounds of the face, when at all extensive, are always followed, in healing, by greater or less deformity. The medical witness may perhaps find these questions put to him in relation to them. Is the wound likely to be attended with deformity? Could such a wound of the face heal without deformity? Or could the deformity, if it exist, have been produced by any other cause than the wound? These questions are of more importance than may at first sight appear. Thus a person may allege that he was severely wounded in the face, when the medical witness, on examination, may find no trace of such a wound as that described. Again, a person may seek damages from another in a civil action, by alleging that a particular deformity was produced by a wound, when the medical witness may be able to trace its origin to disease, or to some accidental cause.

Injuries to the Spine.

Injuries to the spine and spinal marrow seldom require medico-legal investigation; but this organ is liable to concussion from blows, to compression from fracture of the vertebrae, or the effusion of blood, with all the secondary consequences attending such accidents. Concussion of the spinal marrow commonly produces paralysis, affecting the bladder, rectum, or lower extremities. These symptoms may not appear at once, but come on after some hours or days. After death no traces of mechanical injury may be discovered. Blows on the spine, unattended with fracture or dislocation, may, according to the observations of Sir B. Brodie, be followed by inflammation and softening of the spinal marrow. A slight injury has been known to cause death by giving rise to inflammation of the spinal marrow. (See Henke's Zeitschrift der S. A. 1840, ii. 407.) This organ is also liable to compression from very slight causes.

Fractures of the vertebrae.—These fractures are generally attended by displacement and compression of the spinal marrow.
They are the more rapidly fatal, in proportion as the injury is high up in the vertebral column. The whole of the body becomes paralysed below the seat of injury, by the compression of the spinal marrow. If the seat of compression be above the fourth cervical vertebra, death is commonly immediate: asphyxia results from paralysis of the phrenic nerves. In falls on the summit of the head from a height, it sometimes happens not only that the skull is extensively fractured, but that the denticiform process of the second vertebra is broken off, owing to the head being doubled under the body. This injury to the second vertebra may be the cause of death. From a case related by Mr. Phillips, it would appear that this accident is not always attended by fatal compression of the spinal marrow. (E. M. & S. J. Jan. 1838.) In one instance the individual survived fifteen months (ib. Oct. 1845, p. 527); and in another, in which the fracture was caused by the patient turning in bed while his head was pressed on the pillow, death did not take place for sixteen months. (Copland, Dict. Pr. Med.,Paralysis.) On several criminal trials, this injury has been proved to have been the cause of death: and in a case tried at Glasgow some years since (the King against Reid), it became a material question, how far such a fracture might result from disease. It may happen that caries of the bone or disease of the transverse ligament will cause a separation of the denticiform process from the second cervical vertebra. The state of the bone should, therefore, be closely examined. In Reid’s case an acquittal took place, partly because the deceased had laboured under disease of the spine, and the exact state of the parts had not been noticed. Disease of the ligaments may also lead to a separation, followed by slow or rapid death, according to the degree of pressure.

Injuries to the spine and its contents are generally the result of falls or blows either on the head or the lower part of the column. The secondary consequences of these injuries are sometimes very insidious, so as to disarm suspicion, and death may take place quite unexpectedly some weeks after the accident. Spicula of bone separated by fractures may remain adherent for some time; and by a sudden turn of the head, be forced off and destroy life by penetrating the spinal marrow, at a long period after the infliction of the injury. This has been known to happen in fractures involving the margin of the foramen magnum, and in such cases death is immediate. The spinal marrow has been in some instances wounded in its upper part by sharp-pointed instruments introduced between the vertebrae. Death is an instantaneous result when the wound is above the third cervical vertebra;—there is no part of the spine where a weapon can so readily penetrate as this, especially if the neck be slightly bent forward. The external wound thus made may be very small, and if produced with any obliquity by drawing aside the integu-
ments, it might be easily overlooked, or it might be set down as superficial. For a medico-legal account of a case in which death occurred from a stab in the back of the neck, causing a division of the spinal marrow, see Henke, Zeitschrift der S. A. 1839, H. ii. 1836; and for another case of homicidal injury to the spine, reported by Dr. Eade, see Lancet, May 1855, p. 520.

CHAPTER XXXIV.

WOUNDS OF THE CHEST.

Wounds of the chest have been divided into those which are confined to the parietes, and those which penetrate the cavity. This division is important, so far as it relates to the prognosis of such injuries. Incised or punctured wounds of the parietes of the chest are rarely followed by dangerous consequences. The loss of blood is not considerable, and is generally arrested without much difficulty. They heal either by adhesion or suppuration, and unless their effects be aggravated by incidental circumstances, the prognosis is very favourable. Contusions or contused wounds of the chest are, however, far more dangerous, and the danger is always in a ratio to the degree of violence used. Such injuries, when severe, are ordinarily accompanied by fractures of the ribs or sternum,—by a rupture of the viscera within the cavity, including the diaphragm,—by profuse bleeding,—or, as an after-effect, by inflammation of the organs, with or without suppuration. Fractures of the ribs are dangerous for several reasons: the bones may be splintered and driven inwards, thereby wounding the lungs and causing loss of blood, or leading to inflammation of the pleura or lungs. In fractures of the upper ribs, the prognosis is less favourable than in those of the lower, because commonly a much greater degree of violence is required to produce the fracture. A simple fracture of the sternum, without displacement of the bone, is rarely attended with danger, unless the violence has at the same time
produced mischief internally, which will be known by the symptoms. When, however, the bone is depressed as well as fractured, the viscera behind may be mortally injured. In a case of depressed fracture of the sternum, recorded by M. Sanson, the individual died after the lapse of thirteen days; and on inspection, it was found that the fractured portion of bone had produced a transverse wound of the heart about an inch in length. The cavities of the organ had not been penetrated, but the piece of bone was exactly adapted to the depression produced by it on the parietes. (Devergie, Méd. Lég. vol. ii. p. 243.) A practitioner will frequently be required to take into consideration the effects of contusions on the thorax, with or without fracture, in cases of death from pugilistic combats, which of late years have given rise to numerous trials on charges of manslaughter. Cuts or stabs penetrating the cavity of the thorax are generally dangerous, even when slight, in consequence of the numerous accidents with which they are liable to be complicated. In these wounds the lungs are most commonly injured; but, according to the direction of the weapon, the heart, or the great vessels connected with it, as well as the oesophagus or thoracic duct, may share in the mischief.

Wounds and Ruptures of the lungs.—The immediate cause of danger from wounds of these organs is the consequent hemorrhage, which is profuse in proportion to the depth of the wound and the size of the vessels wounded. Should the weapon divide any of the trunks of the pulmonary veins, the individual may speedily sink. The degree of hemorrhage cannot be judged of by the quantity of blood which escapes from the wound; for it may go on internally, and collect within the cavity of the pleura, impeding the respiratory process. This is especially to be apprehended when the external orifice is small and oblique, and one of the intercostal arteries has been touched by the weapon. A wound of the lung is generally known, among other symptoms, by the frothiness and florid colour of the blood which issues from the orifice, as well as by the expectoration of blood. The lungs may sustain serious injury from a blow or fall, and yet there may be no external marks of violence or symptoms indicative of danger for some hours. A young man, while riding, fell from his horse on his left arm. He complained of no pain for five hours, but in twelve hours he was seized with an alarming flow of blood from the mouth. He died in the course of a few days. After death there was no mark of injury to the chest, but the right lung was ruptured posteriorly throughout its length, and much blood had been effused. (Lancet, November 1842.) A case somewhat similar to this is reported by Mr. Jardine, of the Winchester County Hospital. (Med. Times and Gaz. Dec. 31, 1853.) A boy, aged 14, fell to the ground from a height of about twenty feet. He was admitted an hour after the accident, and he died in about two hours after his admission. On examin-
ation of the body twelve hours after death, there was no mark of external injury. The collar-bone was fractured, but the ribs had escaped injury. The right lung was found ruptured to the depth of four inches into its substance, and from this a large quantity of blood had escaped, which caused death. This case furnishes another illustration of the production of fatal internal injuries without any corresponding marks of violence externally. (See ante, p. 251.) During the convalescence of an individual who has survived the first effects of a penetrating wound of the chest, the surgeon should observe whether death, when it occurs, may not have been caused by any imprudence on the part of a patient, or by abuse of regimen or other misconduct; for circumstances of this nature may be occasionally regarded as mitigatory on the trial of an aggressor. It is very properly recommended that, in all cases where a party is progressing to recovery, a relaxation of the antiphlogistic regimen should be made with great circumspection. Too much nourishment, too frequent talking, or any exertion, are circumstances that may cause a renewal of the hemorrhage and extravasation. A case is related, in which a soldier died instantly from internal hemorrhage, brought on by throwing a bowl at some nine-pins, two months after he had been apparently cured of a wound of the lungs.

Wounds of the heart.—Wounds of the heart are among the most fatal of penetrating wounds of the chest. It was formerly considered that all wounds of this organ were necessarily and instantly mortal. (See ante, p. 345.) Undoubtedly, when either of the cavities is laid open to a large extent, the hemorrhage is so profuse on the withdrawal of the weapon, that death must be immediate. But when the wound is small, and penetrates into the cavities of the organ obliquely, life may be prolonged for a considerable period; and cases are on record in which it is probable that such wounds would have healed, and the patients have finally recovered, but for the supervision of other diseases which destroyed life. Dupuytren has reported the case of a man who received a stab on the left side of the chest, on November 5th, 1831. He was brought to the Hôtel Dieu, but the symptoms under which he laboured did not lead to the suspicion that he had received a wound of the heart. The man died on the 13th, of cerebral disease. On inspection of his body, it was found that the left ventricle was wounded about the middle and a little to the right; its cavity having been penetrated in a transverse direction. The wound was three lines and a half across, and one line from above downwards. The external fibres of the organ were most separated; the openings diminished gradually, so that the internal fibres were in contact and closed the wound. A boy, in pulling a knife from a companion with the point towards him, accidentally stabbed himself in the chest. A small quantity of florid red blood escaped; he vomited, and fell to the ground. He died in
eight days. The left ventricle had been perforated, and one pound and a half of blood was effused in the chest. This case shows that fatal hemorrhage is not always immediate. (Med. Gaz. ii. p. 721.) In another instance recorded by Baron Dupuytren, five or six wounds were made by means of a saddler’s needle,—most of them penetrating into the right ventricle of the heart. This man died of cerebral disease, twenty-five days after the wounds could have been possibly inflicted; for the needle was taken from him twenty-five days before his death, without any suspicion being entertained of his having wounded himself with it. The external cicatrix was visible on an inspection of the body. The quantity of blood found in the chest amounted to about three ounces, and this appeared to have proceeded from the substance of the heart. (Med. Gaz. vol. xiii. p. 662.) For cases in illustration of the position that wounds of the heart are not instantaneously mortal, see Med. Gaz. ii. p. 721.

In the opinion of Baron Dupuytren, these injuries are not necessarily fatal, although I believe, with one exception (infra), there is no case on record in which a person has recovered from a penetrating wound of the cavities of the heart. (Ed. M. and S. J. Oct. 1844, 557; also Ann. d’Hyg. 1846, i. 212.) There are few, probably, who will be inclined to consider them curable; a remote possibility of simple wounds healing, and of the patient recovering, may be admitted; but until some clear instances of recovery from penetrating wounds of the cavities are reported, the majority of practitioners will continue to look upon them as fatal. From a series of cases collected by MM. Ollivier and Sanson, it appears that out of twenty-nine instances of penetrating wounds of the heart, only two proved fatal within forty-eight hours. In the others, death took place at the varying periods of from four to twenty-eight days after the receipt of the wound. (Devergie, Méd. Lég. vol. ii. p. 253.) These differences in the time at which death occurs, as well as the fact that wounds of the heart do not instantly destroy life, have been ascribed to the peculiar disposition of the muscular fibres of the organ, and to the manner in which they are penetrated by a weapon. Thus, as a general principle, it is stated that wounds which are parallel to the axis of the heart, are, ceteris paribus, less rapidly fatal than those which are transverse to its axis. In a wound which divides the fibres transversely, the opening will be larger, and the hemorrhage greater, than in one which is parallel to these fibres; and as the heart is composed of different layers, of which the fibres pass in different directions, so, in a penetrating wound of its cavities, while one set tends to separate the edges, another tends to bring them together, and thereby to restrain the flow of blood. It is this action of the fibres which renders wounds of the ventricles less rapidly fatal than those of the auricles, all other circumstances being equal (see case by Mr. Callaway, ante, p. 346); but a man
has been known to survive a laceration of the left auricle eleven hours. In the 17th volume of the Medical Gazette, page 82, a case is reported in which a person is stated to have recovered from a punctured wound of the heart; and Dr. Trugien met with a case in which a man who had been stabbed in the left ventricle survived five days. The wound in the heart had partly cicatrized. (See Med. Gaz. vol. xlvii. p. 42.) In reference to penetrating wounds of the chest, it may be proper to state that the base of the heart corresponds to the upper margin of the third rib on the left side; and the apex to the lower margin of the fifth rib on the same side.

Ruptures of the heart.—The heart is liable to be ruptured either from disease or accident. In the latter case, the organ generally gives way towards the base, and through one of the cavities on the right side. (For cases, see Med.-Chir. Rev. xxxi. p. 532.) Dr. Hope asserts that in ruptures from natural causes, it is the left side of the heart, and particularly the left ventricle, in which a rupture is most frequently found. The symptoms are sudden pain, collapse, cramps, cold extremities, and rapid death. According to the circumstances under which they occur, cases of rupture from disease may excite a suspicion of death from violence. Sometimes the substance of the heart appears to have undergone a fatty degeneration. Dr. Quain met with a case in which, under this diseased condition, the left ventricle had become ruptured during slight muscular exertion. (Med. Gaz. xxxviii. pp. 774 and 857.) Mr. Marshall has reported a case of rupture of the right ventricle under similar circumstances. (Lancet, Feb. 16, 1857.) In other instances there has been no apparent alteration of structure. Dr. Stroud reported to the Med.-Chir. Society, a case of this kind, which occurred in a young man aged twenty-nine. The deceased died in ten hours after his first seizure; on inspection there was a small aperture in the right auricle near the vena cava. This did not appear to be connected with any morbid condition of the heart. (Med. Gaz. xxvi. p. 518; Lancet, Nov. 1843.) As a medico-legal subject, it is worthy of note that when this alarming accident proceeds from blows or falls, it is not always accompanied by marks of external violence, or any fracture or other injury to the exterior of the chest. The natural causes of rupture of the heart are violent mental emotions, such as anger, fright, terror, paroxysms of passion, sudden or excessive muscular efforts, or violent physical exertions in constrained positions. The heart, like any other muscle, may also give way from its own powerful contraction. The left auricle of the heart has been ruptured as a mere result of great physical exertion. (See case, Med. Gaz. vol. xlvii. p. 1063.) Rupture of the heart from any of these natural causes is, however, a very rare occurrence. (Med.-Chir. Rev. Oct. 1847, p. 460.)
WOUNDS OF ARTERIES AND VEINS.

Wounds of arteries and veins.—Wounds of the large arterial and venous trunks, around the heart, must be considered as decidedly mortal: death is generally instantaneous from the sudden and profuse bleeding which attends them. Dr. Heil, of Bamberg, has related a case which he considers to prove that a person may recover from a penetrating wound of the ascending aorta. (Henke’s Zeitschrift, 1837, ii. 459.) With regard to these fatal effusions of blood within the chest, as well as in the other great cavities, it may be proper to mention that, from whatever vessel or vessels the blood may have issued, it is not commonly found coagulated to any extent. The greater part of it generally preserves the liquid state; and it is rare that so much as one half of the quantity effused is met with in the form of coagulum. These effusions of blood in the chest may be sometimes traced to wounds of the intercostal and the internal mammary arteries, or of the vasa azygos.

Wounds of the carotid arteries have been considered in the section on wounds of the throat (ante, p. 263.) Of wounds of the other blood-vessels, whether arteries or veins, it is unnecessary to make any further remark. Death is generally owing to loss of blood, and the bleeding from a comparatively small vessel may prove fatal, according to its situation and the state of the individual.

Death from the entrance of air into wounded veins.—In wounds of veins there is an occasional and a peculiar cause of death which requires notice, namely, the entrance of air by the open mouth of the divided vessel. Among many cases of this kind I select one which occurred to Dr. Willis, of Barnes, in March 1848:—A man was labouring under chronic laryngitis, and it was considered proper to introduce a seton at the fore part of the neck. The skin was raised, and the seton-needle was passed horizontally through the skin, about two inches and a half above the breast-bone, and not at all near the jugular vein or any other important blood-vessel. At the instant of its entrance there was a momentary hissing sound,—the man became pale,—his features were set,—he fainted, and he subsequently became rigid and convulsed. The man did not recover his consciousness, was attacked with lock-jaw, and died in seven hours. From the medical evidence given at the inquest, it was evident that death had not arisen from hemorrhage, but from air penetrating through a small vein which had been accidentally divided. A verdict was returned accordingly. After the inquest the body was inspected, and it was then found that the jugular veins and the large vessels of the neck were uninjured. The right auricle and pulmonary artery were distended with frothy blood, and the lungs were emphysematous. (Med. Gaz. xli. p. 608.) For another case of sudden death from this cause, see Med. Gaz. xliii. p. 1098. See also a paper on this subject in the same journal by Mr. Lane, vol. xlv. p. 926.
It has been long known that air injected into the jugular vein would destroy life by interfering with the functions of the heart. The exact nature of the accident, as it occurs in operations, is not well understood. (Ferguson's Surgery, 444.) According to some, the air rushes into the cavity of the vessel owing to atmospheric pressure during the expansion of the heart, while others believe it to be dependent on the act of inspiration. It is difficult to account for the entrance of air by atmospheric pressure, unless the cut orifice of the vein be kept open, or unless its coats be morbidly thickened, so that it does not readily close when divided; nevertheless, death may thus occur without the slightest imputation on the skill of the operator. Dr. Cormack has shown that in some alleged cases of this kind death was probably due to loss of blood. When the hemorrhage is slight, and the hissing sound is heard at the time of the incision, it may fairly be ascribed to the entrance of air. This opinion would be confirmed by the discovery of a frothy state of the blood in the right cavities of the heart. It is worthy of remark, that death may take place from this cause, although the patient may recover from the first symptoms. A case has been reported in which a patient died in thirteen hours, although he had so far recovered in the interim, that the functions of the lungs and heart were completely restored. (Association Journal, Jan. 28, 1853, p. 91.)

Wounds and ruptures of the diaphragm.—The diaphragm, or muscular partition between the chest and abdomen, is liable to be wounded either by weapons which penetrate the cavity of the chest or abdomen, or by the ribs when fractured by violent blows or falls; but, under any circumstances, wounds of this muscle are not likely to occur without implicating the important organs that are in contact with it. It is scarcey possible, therefore, to estimate the danger of these injuries abstractedly, as the prognosis must materially depend on the concomitant mischief to the adjoining viscera. Slight penetrating wounds of the diaphragm may heal like those of other muscular parts; and cases of this kind are on record. There is, however, especially when the wound is of a lacerated kind, a consecutive source of mischief which no remedial means can avert,—namely, that after the wound has, to all appearance, healed, the life of a person may be cut short by the strangulation of a portion of the stomach or bowels in the half-cicatrizied aperture. An instance reported by Dr. Smith affords an illustration of this. A sharp-pointed weapon had penetrated the diaphragm, notwithstanding which the patient apparently made a rapid and perfect recovery. At the end of about three months, however, the man died from a strangulated hernia or rupture of the stomach, which had passed through the wound of the diaphragm into the thorax. (For. Med. p. 279.) In a case of this description, when death occurs
at a long period after the infliction of a wound, the witness will probably be required to say—Whether the wound was the cause of death? Or whether there were any other circumstances which would have caused or facilitated the production of a hernia? The degree of culpability of an aggressor may materially depend upon the answers returned to these questions. Phrenic hernia, as this form of internal rupture is termed, is not by any means an unusual or unexpected fatal consequence of a wound of the diaphragm; and therefore it would appear, at first sight, that death, at whatever period this event may occur, should be referred to the original wound. But the question is of a very delicate nature; as it is possible that a slight blow on the stomach, received subsequently to the wound, or even any violent exertion on the part of the deceased, might actually produce strangulation.

The most serious injuries to the diaphragm are unquestionably those which are produced by violent contusions, or falls on the abdomen, while the stomach and viscera are distended. In these cases the muscular fibres are commonly found ruptured to a greater or less extent: the hemorrhage is not very considerable, rarely exceeding two, three, or four ounces. A uniform result of these ruptures, when extensive, is a protrusion of the stomach into the chest, with sometimes a rupture of the coats of that organ and extravasation of its contents. Severe lacerations of the diaphragm are more readily produced during the act of inspiration, than during expiration,—the fibres of the muscle being then stretched, and receiving, while in this state of tension, the whole of the force. According to Devergie, the rupture most frequently takes place in the central tendinous structure, where it is united with the left muscular portion above the crura. He has remarked that it is observed more commonly on the left side than on the right. (Op. cit. ii. p. 250.) It has been supposed that death was an immediate consequence of this accident; but this view is not supported by facts. In a case of extensive rupture of the diaphragm, related by Devergie, in which the stomach and colon were found in the chest, the person lived nine months after the only accident which could have produced it, and then died from another cause. Besides the stomach, it sometimes happens that the liver, spleen, or intestines pass through the opening, and, like it, these organs are liable to become strangulated: the lungs are at the same time so compressed that respiration is stopped and asphyxia or suffocation is often an immediate result.

Direction of wounds in the chest—In judging of the direction taken by wounds which traverse the antero-posterior axis of the chest, it is necessary to remember the great difference that exists in the level of the same rib anteriorly and posteriorly. This must be especially attended to, when we are called upon to state the direction of a traversing wound from the description of it given

B B 2
by another. The point here referred to had an important bearing in the case of a fatal gun-shot wound which was the subject of a criminal charge some years since. (Henke's Zeitschrift, 1836.)

**WOUNDS OF THE ABDOMEN.**

*Wounds of the parietes.*—_Incised and punctured* wounds, which affect the parietes of the abdomen, without penetrating the cavity, are not quite of so simple a nature as might at first sight be imagined. The danger is immediate, if the epigastric artery be wounded; for a fatal hemorrhage will, in some instances, take place from a wound of this small vessel. _Contusions_ are attended generally with far more serious effects on the cavity of the abdomen, than on the chest. This arises from the abdominal parietes having less power to resist external shocks. In the first place, death may be the immediate result of a blow in the upper and central portion; no particular morbid changes may be apparent on inspection, and the violence may have been so slight, as not to have produced any ecchymosed mark on the skin. Death has been ascribed in these cases to a fatal shock transmitted to the system, through a violent impression produced on the solar plexus. In a case of manslaughter tried at the Central Criminal Court, in Aug. 1841 (*The Queen against Sayers*), death was thus caused by violence during a pugilistic combat. The man received a blow in the stomach, and fell dead. As there were no marks of external injury, the surgeon thought the man had died of apoplexy! The prisoner was acquitted. A similar case was the subject of a trial at the Norwich Lent Assizes, 1854 (*Reg. v. Laws*). The deceased, a powerful man, received during a pugilistic encounter a blow on the abdomen, and he instantly fell backwards, dead. On an examination of the body there were no marks of injury, either externally or internally. The surgeon attributed death to sudden shock; and this, no doubt, was the true cause. The learned judge left it to the jury to say whether they thought the death of the deceased was caused by a blow; but if they could not say what was the cause of death, or if they should think that death was attributable to excitement and that it was independent of the blow, the prisoner would be entitled to an acquittal. A verdict of Not Guilty was returned. Although the blow was seen to be struck, and was a sufficient cause of death under the circumstances, the jury probably thought that there should be some visible injury to the body; and, in the absence of this, declined to refer death to the violence. Had the jury possessed any medical experience or knowledge on the causes of death, they would have seen their way through this apparent difficulty. Blows on the abdomen, when they do not destroy life by shock, may cause death by inducing peritoneal inflammation. Among many instructive cases of this kind, is one
RUPTURES OF THE LIVER AND SPLEEN.

recorded by Dr. Allen, in which fatal peritonitis followed a very slight amount of violence. (See Lancet, Jan. 5, 1850, p. 29.)

Rupture of the liver.—Blows on the abdomen may also prove fatal by causing a rupture of the liver or other viscera, with extravasation of blood: and, as it has been elsewhere stated (ante, p. 251), these serious injuries may occur without being attended by any marks of external violence. Of all the internal organs, the liver and spleen are the most exposed to rupture, owing to their very compact structure, which prevents them from yielding to a sudden shock, like the hollow viscera. Ruptures of the liver may occur from falls or blows; but this organ may be ruptured merely by a sudden action of the abdominal muscles. An accident of this kind happened to an individual who was endeavouring to avoid a fall from his horse. (Male’s Jur. Med. 119.) A fall on the feet from an elevated spot may also determine laceration of this organ. (Ann. d’Hyg. 1846, i. 133.) Ruptures of the liver are generally seen on the convex surface, seldom extending through the whole substance of the organ, but consisting of fissures, varying from one to two inches in depth. Their usual direction is from before backwards, with a slight obliquity; they rarely intersect the liver transversely. The lacerated edges are not much separated, while the surfaces present a granular appearance. But little blood is met with in the laceration; it is commonly found extravasated in the lower part of the cavity of the peritoneum, or in the hollow of the pelvis, and is only in part coagulated. Ruptures of the liver, unless they run far backwards and involve the vena cava, are not in general attended with any considerable effusion of blood; but the hemorrhage, should this vessel be implicated, is sufficient to cause the instant destruction of life. Under other circumstances, a person may survive some hours (ante, p. 348). Rupture of this organ may take place from violence applied to the chest, and there may be no marks of injury over the region of the liver. (See case, Med. Times, Aug. 30, 1851, p. 234. For other cases, see Med. Gaz. xlvii. 156.)

Wounds of the gall-bladder. — Wounds and ruptures of the gall-bladder are necessarily attended with the extravasation of bile. This irritant fluid finds its way into the cavity of the abdomen, and the individual dies from peritonitis. A fatal case of this description occurred to Dr. Maclachlan. An old man while getting out of bed fell with great violence on the floor. He died from peritonitis in forty-eight hours. The gall-bladder was ruptured, and a large calculus was found impacted in the cystic duct. (Med. Gaz. xxxvii. 968.)

Rupture of the spleen. — Ruptures of the spleen may occur either from violence or disease, and it would appear from the following case, reported by Mr. Heddle (Med. Chir. Rev., Oct. 1839), that a very slight degree of violence is sufficient to rupture
this organ, while there may be no marks of injury externally. A middle-aged man was observed fighting with a boy about fourteen years of age, who in stature scarcely reached to his waist. When the fight had terminated the boy ran away; the deceased was observed to become very weak and faint, and he complained of uneasiness in his left side. He expired a few minutes afterwards. On inspection, no mark of violence could be detected externally; but the cavity of the abdomen contained a large quantity of blood. The spleen was found enlarged, and so softened, that its structure was broken down by the slightest pressure. There was a laceration across its surface, about half an inch in depth, from which the fatal haemorrhage had proceeded. A similar case, in which death occurred in fifteen minutes, is reported in the Medical Gazette, vol. xxxv. p. 942. The rupture was caused by a blow, but there was no mark externally to indicate that a blow had been struck. A case of spontaneous rupture of the spleen, which was enlarged and in a diseased condition, is reported in the same journal for June 1842. Dr. Easton has communicated to me a case (Feb. 1856) in which a little girl died in fourteen hours from rupture of the spleen. This had arisen from the wheel of a cart passing over her body. There was no mark of external violence. It is highly probable, that when the liver and spleen are ruptured from slight causes, the structure of these organs will be found to be in a diseased condition — a circumstance which may in some cases be regarded as mitigatory of the act of the assailant. (See also Med. Gaz. xxxv. p. 942.)

Ruptures of the kidneys.—The kidneys are occasionally ruptured from violence; but this appears to be a rare accident. Two cases were reported by Mr. Stanley to the Med. Chir. Soc. (Lancet, Nov. 1843). In one, the individual recovered; in the other, death did not take place for a considerable time. Another case, which occurred in 1847, has been communicated to me by Dr. Beveridge. It occurred during a scuffle, but its existence was not suspected during life.

Ruptures and wounds of the intestines.—Ruptures of the intestines sometimes occur from disease; and, in a case of rupture alleged to have been produced by violence, we must always take this possible objection into account. The ruptured part of the bowel should be carefully examined, in order to see whether there be any signs of ulceration or softening about it. If not, and there is clear evidence of violence having been used, it is impossible to admit this speculative objection. If with the proof of violence there should also be a diseased condition of the bowel, we may be required to say whether this did not create a greater liability to rupture, — a point which must be admitted. (For medico-legal cases of ruptured intestines, see Watson on Homicide, p. 159; also, Henke, Zeitschrift der S. A. 1836, Erg. H. xxii., and Brit. and For. Rev. iv. p. 519.) I am indebted to Dr. Croker King for a
Ruptures of the stomach and bladder.

Ruptures of the stomach and bladder.

Report of two fatal cases of ruptured jejenum, one arising from a kick on the abdomen and the other from an accidental fall. Dr. King has observed that persons who have sustained this injury retain the power of locomotion and muscular exertion.

Punctured wounds, which merely touch the bowels without laying open the cavity, are liable to cause death by peritonitis. These injuries to the intestines sometimes destroy life by shock; there is but little blood effused, and the wounded person dies before peritonitis can be set up. Severe wounds to the intestines may, however, be inflicted almost without the consciousness of the individual, and the wounded person may be able to walk a considerable distance. (Med. Gaz. xlvi. p. 24.)

Wounds and ruptures of the stomach.—Wounds and ruptures of the stomach may cause death by shock: ruptures commonly give rise to severe pain, which of itself is sufficient to bring about rapid dissolution. It is proper to state, however, that the stomach may become ruptured from spontaneous causes, as in ulceration produced by disease; but sometimes there is no morbid cause to explain the result. In April 1828, a man, aged thirty-four, was brought into St. Bartholomew's Hospital, complaining of severe pain in the abdomen. Ten hours afterwards he was seized with violent vomiting; the pain ceased; the vomiting also ceased; and he died in five hours more. The posterior surface of the stomach was found lacerated to the extent of three inches, and the contents of the organ had escaped through the aperture: the mucous membrane was reddened, but there was no thickening, ulceration, or any apparent disease of the stomach. (Med. Gaz. ii. p. 182: see also Dub. Med. Jour., May 1843; and Ed. Med. and Surg. Jour., Oct. 1843, p. 522.) Penetrating wounds of the stomach generally prove rapidly mortal; they seldom form a subject of medico-legal investigation; but a singular case was tried at the Norwich Assizes in 1832, in which a man was charged with the murder of his wife, by throwing at her a red-hot poker. The weapon completely perforated her stomach, and the woman died in six hours. It might be questioned whether this was a wound in the common sense of the term; it was an injury compounded of a burn, puncture, and laceration.

Rupture of the bladder.—This injury, which has on several occasions given rise to medico-legal discussion, is frequently the result of blows on the lower part of the abdomen. The principal questions to be answered are: Was the rupture the result of wilful violence or of an accidental fall? or, Did it proceed from spontaneous causes, as from over distension? The spot in which rupture commonly takes place is in the upper and back part, where the bladder is covered by the peritoneum. The aperture is sometimes large, at others small; but the effect is, that the urine is effused, and death takes place sooner or later from peri-
peritoneal inflammation. It is commonly stated that ruptures, when attended with extravasation of urine into the peritoneal cavity, are uniformly fatal; but if the rupture occurs in the under part of the bladder, or the urine finds its way into the cellular tissue, the prognosis is not so unfavourable. Mr. Syme has reported a case of recovery under these circumstances. (Surgical Contributions, p. 332.)

The usual period at which death occurs from this accident is in from three to seven days; but Mr. Ellis met with a case in which the person did not die until the fifteenth day. The cause of death is obviously peritoneal inflammation; but a person may die suddenly from this injury as a result of shock. Dr. Paterson has communicated a case of this kind to the Association Journal (Jan. 28th, 1853, p. 88). A man, while struggling with another, received a severe kick in the lower part of the abdomen. He fell backwards, and died immediately. On inspection, the brain was congested, but otherwise healthy; — the heart was free from disease, but much distended with black coagulated blood. The bladder had, on the left side of the body, a rent of about two inches; but this organ was in other respects healthy, as well as the urethra. There was some bloody effusion in the cellular tissue. The peritoneum and viscera of the abdomen were uninjured. There were no marks of violence on the body.

When these ruptures are produced by blows they are rarely accompanied by the slightest mark of ecchymosis, or of injury to the skin. Thus, then, there may be no means of distinguishing, by an external examination, whether the rupture was really due to violence, or to spontaneous causes. They who are unacquainted with this fact, might be disposed to refer the rupture to disease, on the supposition that violence would be indicated by the usual characters externally; but there are numerous cases on record which show that this view is erroneous.

As an attempt may be made, in cases in which death has resulted from this injury, to refer rupture of the organ to natural causes, it may be observed that this is a very unusual occurrence: a rupture is almost always the result of violence directly applied to the part, while the organ is in a distended state. A spontaneous rupture may, however, occur: 1, when there is paralysis, with a want of power to expel the urine; 2, when the bladder is ulcerated or otherwise diseased; 3, when there is an obstruction in the urethra from stricture or other causes. A fatal case of rupture of the bladder arising from obstruction as a result of disease occurred to Mr. Field (Med. Times and Gazette, Dec. 13, 1856, p. 590). The causes of spontaneous rupture are easily recognisable by ascertaining the previous condition of the deceased, or examining the bladder and urethra after death. If a man were in good health prior to being struck,— if he suddenly
felt intense pain, could not pass his urine afterwards, and died from an attack of peritonitis in five or six days; if, after death, the bladder was found lacerated, but this organ and the urethra were otherwise in a healthy condition, there can be no doubt that the blow must have been the sole cause of rupture and death. In such a case, to attribute the rupture to spontaneous or natural causes would be equal to denying all kind of causation. As to the absence of marks of violence externally, this would be a difficulty only to those who had not previously made themselves acquainted with the facts attending this and other accidents affecting the viscera of the abdomen (ante, p. 251). Nevertheless, a medical witness must be prepared to hear the same line of defence continually urged; it is of course the object of a counsel to make the best of a case for the prisoner, and his duty consists in seeing him judged according to law, and not condemned contrary to law. With medical facts, opinions, and doctrines he does not concern himself, so long as they do not serve his purpose.

_Can the bladder be ruptured by an accidental fall, and if so, by what kind of fall?—_The following case, reported by Mr. Syme, shows that this accident may readily occur. A woman, aged twenty-six, fell forwards over the edge of a tub, and fainted immediately. On recovering herself, she complained of intense pain in the abdomen, with inability to pass the urine. Peritonitis came on, and she died in a week. On inspection, a small aperture was found in the upper part of the bladder; the peritoneum was extensively inflamed, from the urine which had become effused. The ruptured surfaces had become partly glued together. (Ed. Med. and Surg. Jour., Oct. 1836.) Rupture of the bladder may take place from an accidental fall, and cause death without necessarily laying open the peritoneal cavity. Two cases of this kind have been reported by Mr. Spencer Wells. (Med. Gaz. xxxvi. p. 621.) The patients were sailors, who fell from their hammocks while in a state of intoxication. The usual symptoms followed,—one died in five, and the other in eight days, from peritonitis; and after death it was clearly found, in one instance at least, that the bladder had been ruptured in the usual situation, but the peritoneum was entire, although in a state of intense inflammation. Another case of this kind, which was the subject of a trial (Reg. v. Dixon, Durham Lent Assizes, 1846), has been communicated to me by M. Steavenson. The prisoner kicked the deceased in the pubic region from behind. The man died from peritonitis in thirty-five hours. On inspection, the bladder was found ruptured near its neck for about half an inch, immediately above and to the left of the prostate gland. The urine had become extravasated into the cellular tissue of the scrotum; but although there was extensive inflammation, the peritoneum was not lacerated. On the
other hand, a remarkable case is reported by Mr. Bower, in which a man died on the sixth day from rupture of the bladder; and after death, although the peritoneum was lacerated, and the cavity of the abdomen was filled with dark-coloured urine, there was no sign of peritoneal inflammation. (Lancet, Dec. 19, 1846, p. 660.) This accident is liable to occur in females during parturition, owing to the pressure of the child’s head; an occurrence which may fix a charge of malapraxis on the medical attendant. He is expected to know the probability of such an accident occurring, and to guard against it, if necessary, by the frequent use of the catheter. In Reg. v. Balsom (Liverpool Lent Assizes, 1838), a surgeon was tried on a charge of this kind. It is important to remember, that although rupture of the bladder is commonly attended, at the time of the occurrence, with intense pain, sickness, and prostration of strength, yet persons may occasionally retain the power of exerting and moving themselves after the accident.

In punctured and incised wounds of the bladder, the urine is immediately extravasated; but in gun-shot wounds, the extravasation does not commonly take place until the sloughs have separated. Thus, life may be protracted longer in cases of gun-shot, than under other wounds of the bladder. Barzellotti relates the case of a medical student, shot through the bladder in a duel, who did not die until the twelfth day, from the peritonitis which supervened on the extravasation. (Questioni di Med. Leg. t. iii. 174.) One instance of a person recovering from a gun-shot wound perforating the bladder, is reported by Mr. Douglas in the Ed. Med. and Surg. Jour. vol. xiii. For the discovery of extravasated liquids or blood, in wounds and other injuries to the abdominal viscera, we must look to the cavity of the pelvis, as it is here that, for obvious reasons, such liquids have a tendency to collect.

Wounds of the genital organs.—Wounds of these organs do not often require the attention of a medical jurist: such wounds, whether in the male or female, may, however, prove fatal to life by excessive hemorrhage. Self-castration or mutilation is not unfrequent among male lunatics and idiots. An inquest was held some time since in London, upon an idiot, who had bled to death from a wound of this description. When timely assistance is rendered, a fatal result may be averted. Incised, lacerated, or even contused wounds of the female genitals, may prove fatal by loss of blood, not from the wound involving any large vessel, but from the numerous small vessels which are divided. Two females were in this way murdered in Edinburgh some years since. The wounds were inflicted by razors, and the women bled to death. (See cases by Watson, p. 104.) This crime appears to have been at one time frequent in Scotland. When deeply incised wounds are inflicted upon the genital
WOUNDS OF THE GENITALS.

organs of either sex, the fact of their existence in such a situation at once proves wilful and deliberate malice on the part of the assailant. (See case, ante, pp. 255, 262.) Accident is wholly out of the question, and suicide is improbable, except in cases of confirmed idiocy and lunacy. Such wounds require to be carefully examined; for the proof of the kind of wound, when fatal, may be tantamount to the proof of murder.

A practitioner may be sometimes required to determine whether wounds affecting the female organs have resulted from accident, have been self-inflicted, or inflicted by others with homicidal intention. In June 1842, a woman received a wound in the genitals by a cutting instrument, on the left side, to the extent of one inch and a half in a longitudinal direction. There was a smaller wound on the right side. The accused alleged that the woman had inflicted the injury on herself; and Dr. Easton, of Glasgow, on being required to state his opinion on the question at issue, came to the conclusion: 1. From the regular edges of the wounds, that they had been produced by a clean cutting instrument, and therefore could not have been caused by a fall, excepting the person had fallen upon some sharply-cutting projection. 2. If the woman had injured herself by thrusting a knife into the private parts, the situation and direction of the wounds would have been different. There was a want of proof to connect the prisoner with the act, and he was discharged. This is an improbable situation for the self-infliction of wounds with a view to suicide. Some rules which have been elsewhere given (ante, p. 261) may enable the witness to form an opinion when a question of this kind is involved in doubt. (For a case in which such a wound was homicidally inflicted upon a male, see Ann. d’Hyg. 1848, i. 443, and for another which led to a trial for the murder of a female, see Med. Gaz. xlv. p. 813.)

Contused wounds on the female genitals prove sometimes fatal by the laceration of parts leading to fatal hemorrhage. Several trials for manslaughter have taken place in which this was proved to have been the cause of death. (See the case of Rey. v. Cawley, Liverpool Winter Assizes, 1847, also a paper by Mr. Barrett, Assoc. Med. Journal, June 28, 1856, p. 535.) There may be such a loss of blood in these cases as to destroy life, although no large blood-vessel be implicated in the injury. A contused wound on the vulva may occasionally present an ambiguous appearance and be mistaken for an incised wound. When the soft parts of the body are struck by a blow or kick, if there be a bony surface beneath, a longitudinal rent may appear as a result of the force being received by the bone beneath (ante, p. 257). A blow on the cranium with the fist produced in one instance a rent which was at first mistaken for a cut. A kick on the vulva, or a fall on this part, may produce a similar injury, and unless
carefully examined, may lead to the inference that a weapon has been used for its production. Mr. Barrett, in the paper above referred to, has properly directed attention to this subject. A case in which a contused wound of the clitoris proved fatal has been communicated to the Lancet by Mr. Gutteridge. (Oct. 31, 1846, p. 478.) A woman, aged 36, received a kick from her husband in the lower part of the abdomen while she was in a stooping posture. She was seen by Mr. Gutteridge in about three-quarters of an hour, and she had then lost from three to four pounds of blood. She was sinking, and expired in a few minutes after his arrival. On inspection, there was no injury to the uterus or vagina; but the wound was seen at the edge of the vulva, extending from the pubis along the ramus of that bone. It was about an inch long and three-quarters of an inch deep. The left crus clitoridis was crushed throughout its length, so as to exhibit its cavernous structure. From this the fatal bleeding had proceeded. The heart and great vessels contained no blood. The bleeding from such injuries is always likely to be more profuse when the female is pregnant. A case of recovery from a contused wound to the genitals in a pregnant female, aged 40, is reported by Dr. M'Clintock. It is stated that there was profuse hæmorrhage from a laceration involving the urinary passage, but under early treatment the woman did well. (Medical Times, May 15, 1847, p. 233.) It is well known that some females are subject to frequent discharges of blood from the genital organs from natural causes. When the bleeding immediately follows a blow, and a female has not been subject to such a discharge, the fair presumption is that violence was the cause; but when the flow of blood appears only a long time after the alleged violence, of which no traces can be seen, it is most probably due to natural causes. A case of this kind has been communicated to me by Mr. Procter, of York. There was no difficulty in giving an opinion that the flow of blood was not due to violence.

It may be alleged in defence that the injuries found on the body were inflicted after death, and not while the deceased was living. Kicks or blows on the vulva, if they destroy life at all, cause death by copious effusion of blood. Violence to this part after death would not produce such an effusion as would account for death. There are also other distinguishing characters which have been elsewhere pointed out (see ante, p. 237). A case was tried in Edinburgh, in which this defence was set up; but Dr. Simpson was enabled to say, from his observation of the effects of such violence to a dead body, that the injuries in question could not have been produced after death.
CHAPTER XXXV.

FRACTURES—PRODUCED BY A BLOW WITH A WEAPON OR BY A FALL—OCURR IN THE AGED—BRITTLENESS OF THE BONES—FRACTURES CAUSED BY SLIGHT MUSCULAR EXERTION—IN THE LIVING AND DEAD BODY—HAS A BONE EVER BEEN FRACTURED?—QUESTIONS OF SURVIVORESHIP—DISLOCATION FROM VIOLENCE OR NATURAL CAUSES—DIAGNOSIS—ACTIONS FOR MALAPPROXIS.

FRACTURES.

Fractures of the bones have some important bearings in relation to medical jurisprudence. They may result from falls, blows, or the spontaneous action of muscles.

Cause. — Questions sometimes arise — 1, whether a particular fracture was caused by an accidental fall or a blow? and, 2, if by a blow, whether by the use of a weapon or not? It is obvious that the answers must be regulated by the circumstances of each case. In examining a fracture, it is important to determine, if possible, whether a weapon has or has not been used; and this may be sometimes known by the state of the parts. It is a common defence on these occasions, to attribute the fracture to an accidental fall. Fractures more readily occur from equal degrees of force in the old, than in the young; and in the young, rather than in the adult; because, it is at the adult period of life that the bones possess their maximum degree of firmness and solidity. The bones of aged persons are sometimes very brittle, and slight violence will then produce fracture. This has been regarded as an extenuating circumstance, when the fracture was followed by death. Certain diseases, such as the venereal disease, gout, rheumatism, cancer, scurvy, and rickets, render the bones more fragile; but they are sometimes preternaturally brittle in apparently healthy persons, and this brittleness appears occasionally to be hereditary. (Dub. Hosp. Gaz., Feb. 1846, p. 189.) In such cases, a defence might fairly rest upon an abnormal condition of the bones, provided the violence producing the fracture was slight. Several trials have taken place in which this brittleness of the bones became a subject of inquiry. In a case of fractured skull leading to death from inflammation of the brain, it was proved that the bones of the skull were unusually thin and brittle, and this led to a mitigation of punishment. (Reg. v. Kennedy, Gloucester Winter Assizes, 1855.)

Spontaneous fractures. — Supposing that there are no appearances of disease, the fracture may be ascribed to spontaneous causes. Thus bones have been fractured by moderate muscular exertion. The olecranon, os calcis, and patella, are particularly
exposed to this accident. The long bones are seldom the subject of an accident of this kind; but the os humeri or arm-bone, in a healthy man, has been broken by the simple muscular exertion of throwing a cricket-ball. (Medical Gazette, xvi. 659.) Mr. May has reported the case of a young lady, who fractured the neck of the scapula or blade-bone, by suddenly throwing a necklace round her neck. (Med. Gaz., Oct. 1842.) It is probable that in such cases, if there were an opportunity of examining the bone, it would be found to have undergone some chemical change in its composition, which had rendered it brittle. A case of spontaneous fracture of the femur was brought into Guy's Hospital in December 1846. A healthy man, 33, of temperate habits, was in the act of placing one leg over the other to look at the sole of his foot, when he heard something give way, and the right leg immediately hung down. On examination, it was found that the right os femoris had been transversely fractured at the junction of its middle with the lower third. This case is remarkable, inasmuch as spontaneous fractures of the thigh-bones are very rare,—as the man had not suffered from any of those diseases which cause preternatural fragility, and the fracture was not caused by violent muscular exertion. The actual condition of the bone was of course unknown; but it healed readily, and the man left the hospital at the usual period. In fractures arising from this cause there will be no abrasion of the skin, nor any appearance to indicate that a blow has been struck, while the marks of a blow would, of course, remove all idea of the fracture having had a spontaneous origin. Fractures are not dangerous to life, unless, when of a compound nature, they occur in old persons, or in those who are debilitated by disease or dissipated habits. They may then cause death by inducing irritative fever, erysipelas, gangrene, tetanus, or delirium tremens.

Fractures in the living or dead body. — It is not always easy to say, whether a fracture has been produced before or after death. A fracture produced shortly after death, while the body is warm, and another produced shortly before death, will present much the same characters, except, perhaps, that in the former case there would be less blood effused. A fracture caused ten or twelve hours before death, would be indicated by a copious effusion of blood into the surrounding parts, and between the fractured edges of the bones, as well as laceration of the muscles; or if for a longer period before death, there may be the marks of inflammation. Fractures caused several hours after death are not accompanied by an effusion of blood. A medical witness may be asked, How long did the deceased survive after receiving the fracture? This is a question which can be decided only by an examination of the fractured part. Unless the person has survived eighteen or twenty-four hours, there are commonly no appreciable changes. After this time, lymph is poured out from the
surrounding structures. This slowly becomes hard from the deposition of phosphate of lime, and forms what is called "callus." In the process of time, this acquires all the hardness of the original bone. The death of a person may take place during these changes, and a medical man may then have to state the period at which the fracture probably happened, in order to connect the violence with the act of a particular person. Unfortunately, we have no satisfactory data, if we except the extreme stages of this process, upon which to ground an opinion. We can say whether a person lived for a long or a short time after receiving a fracture, but to specify the exact time is clearly impossible; since this process of restoration in bone varies according to age, constitution, and many other circumstances. In young persons, bones unite rapidly; in the old slowly; in the diseased and unhealthy, the process of union is very slow, and sometimes does not take place at all. According to Villermé, the callus assumes a cartilaginous structure in from sixteen to twenty-five days; and it becomes ossified in a period varying from three weeks to three months. It requires, however, a period of from six to eight months for the callus to acquire all the hardness, firmness, and power of resisting shocks possessed by the original bone. A force applied to a recently united bone will break it through the callus or bond of union, while, after the period stated, the bone will break as readily through any other part. It is generally assumed, that the period required for the union of a simple fracture, is, for the thigh-bone, six weeks; for the tibia, five weeks; for the os humeri, four weeks; and for the ulna and radius, three weeks; for the ribs, about the same period: but cases have been known where the ribs had not perfectly united in two months, and in some fractures of the other bones, union had not taken place in four months.

Has a bone ever been fractured? — This question is sometimes put in reference to the living subject. It is well known that a bone seldom unites so evenly that the point of ossific union is not indicated by a node or projection. Some bones are so exposed as to be well placed for this examination, as the radius, the clavicle, and tibia,—these being but little covered by skin; in others the detection is difficult. It is impossible for us to say when the fracture took place; it may have been for six months or six years, — as, after the former period, the bone undergoes no perceptible change. These facts are of importance in relation to the dead as well as to the living; since they will enable us to answer questions respecting the identity of skeletons found under suspicious circumstances: and here medical evidence may take a wider range, for a fracture in any bone may be discovered, if not by external examination, at least by sawing the bone longitudinally through the suspected broken part, when, should the suspicion be correct, the bony shell will be found thicker and less regular
in the situation of the united fracture than in the normal state. So, in such cases, it will be easy to say whether a fracture is recent or of old standing. In the case of Clarke, who was murdered many years since by Eugene Aram, the traces of the fracture and indentation of the temporal bone were plainly distinguished on the exhumation of the skeleton of the deceased thirteen years after the perpetration of the murder. The manner in which the murder was committed was confessed by an accomplice, and the medical evidence corroborated this confession. An instance of the utility of this kind of knowledge came out on the trial of a gentleman in India, in 1833, for the murder of a native, Meer Khan. There was some reason to suppose that the prisoner had been falsely accused of causing the death of the native. Two witnesses deposed that a few hours before the death of the deceased, the prisoner had struck him several blows on the chest, and had broken his ribs. The alleged murder having taken place some months previously to the trial, a skeleton was produced as being that of the deceased, by one of the persons who had assisted in burying the body. On examining the ribs, the medical witness found that only one rib was broken, and the fractured portions were united by a firm osseous callus. He therefore declared, that the fracture could not have been caused a few hours before death; but that it must have existed for a period of at least eight or twelve days. Hence the account given by the witnesses was rendered improbable; for the prisoner had used no violence to the deceased, except just before his death; the fracture must therefore have taken place from another cause some time previously. The witness much understated the period at which the fracture probably occurred; for ossification only commences in the cartilage about the sixth day, and the specks of bony matter continue to increase from the eighth to the twelfth day; but the union is soft, and some weeks elapse before the callus becomes firm and hard as it is here described to have been.

Locomotion.—With respect to the power of locomotion after a fracture, it may be observed, that when the injury is in the arm or in the ribs, unless many of them be broken, an individual may move about although unfitted for struggling or great exertion. Fractures of the leg incapacitate a person from moving except to very short distances. See case by Syme, Ed. Med. and Surg. Journal, Oct. 1836. (The reader will find additional information on this subject in the Ann. d’Hyg. 1839, ii. 241; and 1844, ii. 146.)

DISLOCATIONS.

Dislocations are not very frequent in the old or in those persons whose bones are brittle. They rarely form a subject for medico-legal investigation. A witness is liable to be asked, what degree of force, and acting in which direction, would produce a
dislocation,—a question not difficult to answer. They are not
dangerous to life, unless of a compound nature, when death may
take place from secondary causes. A dislocation which has
occurred in the living body may be known after death by the
laceration of the soft parts in the neighbourhood of the joint,
and by the copious effusion and coagulation of blood. [For an
account of the appearances presented by a dislocation of the
humerus four days after death, see Med. Gaz. xxxvi. p. 256.]
If of
old standing, a dislocation would be identified by the cicatrices in
surrounding structures. Dislocations may occur from natural
causes, as from disease and destruction of the ligaments in a
joint; also from violent muscular spasm during an epileptic
convulsion. Dr. Dymock met with an instance of dislocation of the
humerus forwards during puerperal convulsions. (Ed. Med. and
Surg. Journal, April 1843; see also Lancet, April 1845, p. 440.)
A power of locomotion may exist except when the injury is in the
lower limbs; but it has been observed, that for some time after
a dislocation of the hip-joint, considerable power over the limb
remains; it is only after a few hours that the limb becomes fixed
in one position. Exertion with the dislocated member is in all
cases out of the question.

Diagnosis—malapraxis.—There are certain fractures of an ob-
scure kind which closely resemble dislocations. This has been
pointed out by Sir A. Cooper, in relation to fractures of the anat-
No. ix. p. 272.) This accident might be easily mistaken for a
dislocation of the shoulder. (Med. Gaz. xxxvi. p. 38.) In at-
temming to reduce the bone, the head continually falls back into
the axilla. In such a case an action for malapraxis might be
brought against a surgeon, and heavy damages recovered. It
could only be by a dissection of the part after death that the
real nature of the case would be ascertained. It is requisite,
therefore, that great caution should be used in giving an opinion.
The same observations apply to fractures of the neck of the
thigh-bone, although with less force, because this is a much
more common accident. It is well known that fractures and
dislocations, when cured, are often attended either with some
slight deformity of the limb, or with some impairment of its
functions. This result is occasionally inevitable under the best
treatment; but it is commonly set down as a sign of unskilful-
ness in the medical attendant. Actions for malapraxis are insti-
tuted, and, in spite of good evidence in his favour, the surgeon is
sometimes heavily fined for a result which could not be avoided.
There is often great injustice in these proceedings, and the mis-
chief can only be remedied by referring the facts to a competent
medical tribunal which alone should be empowered to decide
whether or not unskilfulness had really been shown in the ma-
nagement of a case.

cc
CHAPTER XXXVI

Gun-shot wounds are of the contused kind, but they differ from other wounds in the fact that the vitality of the parts struck by the projectile is destroyed, and this leads ultimately to a process of sloughing. The legal definition of a wound applies here as in other cases, so that, in order to constitute a gun-shot wound within the meaning of the statute, the cutis, or true skin, must be injured. In the case of the Queen against Mortlock (Cambridge Lent Assizes, 1843), the surgeon deposed that there was a circular wound on the skin, by which it had been deprived of its cuticle, but the true skin was not penetrated. The bullet had struck obliquely at a considerable angle; had it been otherwise, it must have entered the abdomen. The judge said that, as the true skin was not penetrated, there was no wounding within the meaning of the statute.

Their danger. — The medico-legal questions which arise out of gun-shot wounds, are much the same as those which have been examined in relation to other wounds. They are dangerous to life, especially when they penetrate or traverse any of the great cavities of the body. Death may take place directly from loss of blood or shock; although immediate or copious bleeding is not a common character of these injuries. Death from shock is occasionally witnessed. In the case of Daly, who was killed by a pistol-bullet in Hornsey Wood, May 1842, it was found, on inspection, that the bullet had traversed the distended stomach at the greater end from behind forwards. The two apertures were about the size of a shilling, and the edges black. There was but little blood effused, and the other viscera were uninjured. The deceased died a few seconds after receiving the wound, obviously from a shock to the nervous system. (Lancet, May 1842.) Indirectly, these wounds are attended with much danger; sloughing generally takes place uniformly throughout the whole of the parts perforated, and inflammation or fatal bleeding may cut short life. If the individual survive the first effects, he may die at almost any period from suppurative fever, erysipelas, gangrene, or from the results of operations absolutely required for his treatment. Gun-shot wounds may thus destroy life after very
long periods of time. Marshal Maison, one of Napoleon’s generals, died in Paris in 1840 from the effects of a gun-shot wound received, it is said, forty years before. In gun-shot wounds of a severe kind, the first symptoms by no means indicate the degree of mischief. Thus in the case of Mr. Drummond, who was shot by McNaughten, in January 1843, the symptoms were in the first instance so slight, that the bullet was supposed not to have penetrated the cavity of the abdomen, but to have coursed round the skin. Death took place in a few days, and it was then found that the bullet had completely traversed the abdomen, perforating the diaphragm. Army surgeons have also remarked that slight wounds of the parietes are often insidiously attended with deep-seated injury. Death might in such a case be improperly ascribed to mismanagement, when it may have been really due to the wound. (See cases by Mr. Alcock, Med. Gaz. xxiv. p. 850.) It is not easy to mistake a gun-shot wound for any other injury. If the circumstances under which it is produced do not satisfactorily account for its origin, a simple examination will suffice to show its true nature. Sometimes the projectile, or a part of the dress, is found lodged in the wound.

On the living and dead body.—A medical witness may be asked, whether the wound was inflicted before or after death. It is by no means easy to answer this question, unless the bullet has injured some vessel, when the effusion of blood, and the formation of coagula, will indicate that the person was living when it was received. In a gun-shot wound on the dead, no blood is effused, unless the bullet happens to strike a large vein.

Was the piece fired near or from a distance?—A gun-shot wound produced by the muzzle of a piece being placed near to the surface of the body, has the following characters:—There may be two apertures, the one of entrance and the other of exit; but it sometimes happens that the bullet lodges and does not pass out. The edges of the aperture of entrance are torn and lacerated, and appear blackened, as if they had been burnt: this arises from the heat and flame of the gunpowder at the moment of explosion. The skin is often ecchymosed, and is much blackened by the powder:—the clothes covering the body are blackened by the discharge, and sometimes ignited by the flame. If the muzzle of the piece was not in immediate contact with the part struck, the wound is rounded; but if there has been direct contact, the skin, besides being burnt, is torn and much lacerated. The bleeding is usually slight, and when it occurs it is more commonly observed from the orifice of exit, than from that of entrance. It should be remarked, that the aperture of entrance is round, only when the bullet strikes point-blank or nearly so. If it should strike obliquely, the orifice will have more or less of an oval or valvular form; and by an observation of this kind we may sometimes determine the relative position of the assailant.
with respect to a wounded person. Supposing the bullet to have been fired from a moderate distance, but so near as to have had sufficient momentum to traverse the body, then the appearance of the wound will be different. The orifice of entrance will be well defined, round or oval, according to the circumstances, — the skin slightly depressed, — the edges presenting a faintly bruised appearance, but the surrounding parts are neither blackened nor burnt, and they do not present any marks of bleeding. In all cases the orifice of exit is large, irregular, the edges somewhat everted, and the skin lacerated, but free from all appearances of blackness or burning: it is generally three or four times as large as the entrance-aperture. This is denied by Dr. Maile (Ann. d’Hyg. 1840, i. 458), but it appears to me upon insufficient grounds. The orifice of entrance is generally large and irregular when the bullet strikes near the extremity of its range. Under common circumstances, the entrance-aperture has generally the appearance of being smaller than the projectile, owing to the elasticity of the living skin. (Ann. d’Hyg. 1839, ii. 319.) It is the same with the aperture in the dress, when this is formed of an elastic material: — according to Dupuytren, the hole in the dress is always smaller than that made by a bullet in the skin. These points should be remembered in fitting projectiles to wounds which they are supposed to have produced. Useful evidence may be sometimes obtained by a careful examination of the projectile, which, if found, should be preserved by the medical witness for the purpose of identity. When the projectile cannot be found, and there are no marks of burning, or other signs of a near wound on the skin, we must be cautious in expressing an opinion. Mr. Ward has reported a case in which a perforating wound of the skull closely resembled a bullet wound. (Med. Gaz. xlv. p. 767.)

The question whether a piece was fired near to or at a distance from the wounded party, may become of material importance on a charge of homicide, or of alleged suicide. Two persons may quarrel, one having a loaded weapon in his hand, which he may allege to have been accidentally discharged, and to have killed the deceased. If the allegation be true, we ought to find on the body the marks of a near wound: if, however, it were such that it had been produced from a distance, and therefore after the quarrel,—the medical proof of this fact might imply malice, and involve the accused in a charge of murder. The following case occurred in Ireland in 1834: — A tithe-collector was tried for the murder of a man, by shooting him. It appeared in evidence, that the prisoner, while on duty, was attacked by the deceased and two of his sons, and he drew a pistol to intimidate them. He was dragged off his horse by these parties, and during the scuffle, it is supposed, the pistol was discharged accidentally, and inflicted a wound on the deceased, of which he died shortly after-
wards. The sons of the deceased swore that the prisoner took a
deliberate aim, and fired the pistol at t' eir father when at some
distance; and a priest came forward to depose, that such was
the dying declaration of the deceased. From some doubt of the
truth of this story, the body, which had been carelessly inspected
in the first instance, was ordered to be disinterred. It was care-
fully examined by a surgeon, who was enabled to swear posi-
tively, that the pistol must have been fired close to the body of
the deceased, and not at a distance; since there were the marks
of powder and burning on the wrist. Hence it clearly followed,
that the pistol had been discharged during the scuffle, either by
accident or in self-defence. The prisoner was acquitted, and the
parties who had appeared as witnesses against him, were indicted
and convicted of perjury. In the case of Mr. Pearce, a surgeon,
who was tried at the Central Criminal Court, in 1840, for shoot-
ing at his wife, and was found insane, it appeared from the
medical evidence that the pistol had been fired so near to the
person of the prosecutrix, that her dress was burnt and the skin
blistered. Mr. Marshall relates that when stationed at Ceylon
with troops, a man, who had but recently joined the regiment,
was placed as sentry in a position where he was occasionally fired
at by the enemy from the surrounding jungle. The man was one
day found severely wounded; the calf of his leg was greatly torn;
the whole charge of a musket having passed through it. He
attributed the wound to a shot from the enemy; but from the
skin of the leg having been completely blackened by charcoal,
it was clear that it must have arisen from the discharge of his
own musket. He had inflicted this wound upon himself, in order
to obtain a discharge from the regiment. These examples, then,
show that both the dress and skin of a person who has received
a gun or pistol-shot wound should be closely examined. The
result may be, that the statement given of the mode in which a
wound was received, will be entirely disproved. The case of M.
Peytel, tried in France, in September 1839, furnishes an addi-
tional illustration. This gentleman was travelling in a carriage,
in company with his wife, and attended by a man-servant. The
wife and the man-servant were found dead on the road, and the
account given by M. Peytel was, that the servant had discharged
a pistol into the carriage and shot his wife, and he had afterwards,
pursued and killed him. The facts, however, were so suspicious
against M. Peytel, that he was charged with the double murder.
From an examination of the body of the wife, it appeared that
there were two pistol-wounds in the face which had most prob-
ably been produced by two separate pistols. The prisoner alleged
that about nine o'clock at night, when it was dark, he desired
the servant to get down and walk in order to relieve the horses.
Two minutes afterwards, some man, whom he found to be the
servant, approached the carriage-door, discharged a pistol at

389

\[ c \cdot c \]
him, and wounded his wife; but the evidence showed that two weapons must have been used, or at least two different discharges made by a person sitting very near to the deceased, so that the muzzles must have almost touched her face, the eyelashes and skin having been much burnt by the powder. These facts, together with other strong circumstances against him, led to the prisoner's conviction. The late Dr. Ollivier, who appeared in the prisoner's favour, considered that the deceased might have been shot by the servant, and that the two wounds might have been produced by one pistol loaded with two bullets; also, that the marks of burning about the face of the deceased might be attributed to the wadding, and therefore they afforded no proof that the muzzle of the pistol had, at the time of its discharge, been close to her person. He also contended that the deceased had not died from the wounds. Notwithstanding these ingenious suggestions, there can be no doubt that the prisoner was very properly convicted. (See Ann. d'Hyg. 1839, ii. 339; 1842, i. 368.)

It has been said that when a bullet is fired near, it commonly traverses the body; and therefore it has been rather hastily assumed, that where there is only one external wound, and the bullet has lodged in the body, this is a proof that the piece has been fired from a distance. This inference is, however, erroneous. A bullet may be fired close to the person, and yet not traverse the body, either from its impulsive force not being sufficiently great, or from its meeting a great resistance in its course. Many cases might be cited to show, that in the near wounds produced by suicides and murderers, the bullets have not always traversed the body. (See ante, p. 346.) In suicide, when the piece is discharged into the mouth, the projectile often lodges in some part of the cranium.

Evidence from several wounds.—When several wounds are found on a body; — can we determine whether they were produced by one or several different discharges? This question was raised in Peytel's case, as there were two wounds on the deceased, and the prisoner alleged that the servant had fired but one pistol. M. Ollivier thought that this might be explained by supposing that there had been two bullets in the pistol: — it was, however, affirmed by some military officers and other witnesses, that these wounds had been produced by separate pistols, a fact which overthrew the defence of the prisoner. (Ann. d'Hyg. 1842, i. 368.) It is proper to remark that one ball may sometimes produce several wounds on the body; there will be only one orifice of entrance, but owing to the ball occasionally splitting within the body, and dividing itself into three or four pieces, there may be several orifices of exit. This splitting of a ball has repeatedly occurred when the projectile in its course has encountered an angular surface, or a projecting ridge of bone.
DEFLECTION OF BALLS.

Dupuytren met with an instance, in which a ball, after having struck the ridge of the tibia, divided itself into two parts, which traversed the calf of that leg, and penetrated into the calf of the opposite leg. Thus no fewer than five wounds were produced in one instance by a single ball; three of entrance, and two of exit. Had this man been found dead, and nothing known concerning him, this singular circumstance would probably have given rise to considerable embarrassment. After a careful examination, a surgeon might have been induced to declare, that this person must have received at least three distinct shots. A similar effect was observed in another case, in which the bullet struck the parietal bone and divided itself into two portions:—one passed out superficially through the integuments, the other penetrated into the brain, and lodged on the tentorium. This fact shows, that the discovery of an exit-aperture does not always prove that the whole of a projectile has passed out,—a matter which may influence a medical opinion as to the result.

Deflection of balls.—When a ball traverses the body, it sometimes happens that the two apertures are opposite to each other, although it may not have taken a rectilinear course between them, but have been variously deflected by the subjacent soft parts. This deflection of a ball from a rectilinear course is met with in those cases in which it happens to strike obliquely a curved surface, and it is found that when the ball enters and does not pass out, its course is often extremely circuitous, so that it is not always easy to say in what part of the body it may be found. In 1830, I saw at the Hôtel-Dieu, a boy who had received a gun-shot wound in the upper part of the abdomen: the entrance-orifice was very plainly situated there, but there was an opening at the back, nearly diametrically opposite, out of which the ball had passed, so that it conveyed the impression that the ball had completely traversed the abdominal cavity. There was, however, no sign of collapse or depression, nor any indication of serious injury; and Dupuytren gave an opinion, which was afterwards verified,—that the ball had not penetrated, but had been deflected beneath the skin, and had taken a circuitous course through the cellular membrane to the back. Many similar facts are recorded. The same deflection may occur even when the piece is discharged close to the body, as in cases of suicide. Mr. Abernethy was once called to examine a man, who had shot himself, as it was supposed, through the head. He found two openings in the scalp, nearly opposite to each other; it was soon perceived, on examination, that the ball had not penetrated the bone, but had followed the curve of the exterior of the skull to its point of exit. The deflection of projectiles may occur not merely when they come in contact with bone, but when they meet skin, muscles, tendons, or membranes,—the ball then takes its course in the spaces between these different structures. A ball which entered at the ankle
has been known to make its exit at the knee; and another, which entered at the back of the left shoulder, passed down on the inside of the scapula, and was found below the right ear. This deflection of balls by such slight obstacles has been ascribed partly to the obliquity with which they strike, and partly to the rotary motion on its axis which every spherical projectile is considered to have. It does not appear to be much connected with the degree of velocity, for the same deviation, has been found to occur when the bullet was fired near or at a distance.

If we can at any time discover two fixed points where a ball has touched a building, without being reflected, it will be easy to determine the situation from which the piece was discharged. A singular example of this kind is stated by Mr. Watson to have occurred at Ayr in 1831. Several shots had been maliciously fired into a church. Some of the bullets traversed a window, making holes in the glass, and struck against a wall on the other side of the church,—a fact plainly indicated by the marks which they left. A straight line carried from these two points reached a window on the opposite side of the street, from which it was afterwards ascertained the bullets had been fired.

Survivorship.—A witness may be asked,—When was the gun-shot wound inflicted, and how long had the wounded party survived after receiving it? A gun-shot wound undergoes no change for eight or ten hours after its infliction. Our judgment may be assisted by observing what parts are involved, although we cannot always infer from the quantity of blood found near, that the hemorrhage was an immediate consequence of the wound, or that the whole of the blood was effused at once. We cannot, then, always affirm that the deceased could not have moved or exerted himself in some degree, after receiving it. The exertion thus made subsequently to his being wounded, may have actually caused the fatal bleeding.

Suicidal, or Homicidal wounds.—When it is doubtful whether the wound was the result of suicide or homicide, the point may be often settled by paying attention to its situation and direction. Suicidal gun-shot wounds are almost always directed to a vital part,—to the heart or to the brain;—they possess those characters which belong to wounds inflicted near to the body: the skin is blackened or burnt, the wound wide and lacerated,—the hand which discharged the weapon often blackened,—and sometimes still grasping the pistol. The ball may or may not have traversed, as this will depend on the momentum which it derives from the charge, and the resistance that it experiences. (See the case of the Queen v. Thomas, Brecon Lent Assizes, 1845.) The situation in this instance negatived the supposition of suicide. Suicidal gun-shot wounds are seldom situated at the back of the body; therefore the determination of the point of entrance, if the
ball has traversed, is of some importance. The direction of these wounds is probably of less moment than their situation, because the projectile is liable to be deflected in the body. In a duel which occurred in Paris, in 1827, one of the parties, a tall man, was killed by a ball which was found to have entered below the right shoulder, and to have taken a direction downwards. In consequence of this, it was thought that he had been shot unfairly by his antagonist, who was short in stature. Breschet and others explained the suspicious course of the wound, by saying that the ball had struck the under part of the clavicle, and had thence probably been deflected downwards. This question excited considerable attention at the trial of a Dr. Smith for the murder of William Macdonald, at St. Fergus, in Scotland (High Court of Justiciary, Edinburgh, April, 1854.) It appeared from the evidence that the deceased was found dead in a field belonging to the prisoner, on the morning of Sunday, the 20th November, 1853. The body, according to the testimony of eye-witnesses, was lying at full length on the left side in a ditch. The left arm was partly beneath him, and the right partly across the body. There was a blackened wound or hole in the cheek, and a little blood on the cheek. A pistol was lying on the ground, according to one witness, about four feet from the head of the deceased. The time at which the deceased died was fixed with tolerable precision at twenty-five minutes to eight o'clock on the evening of the 19th November; and although the prisoner was not seen near the spot, there was evidence that he had made an appointment to meet the deceased that evening, and the testimony of many witnesses showed that he had had an opportunity of being on the spot at the time when the discharge of a pistol was heard. The defence was, that this was an act of suicide. The pistol could not be identified as belonging to the prisoner; and one witness for the defence positively swore that, six years before, he had sold to the deceased a pistol resembling that found near his body! Upon this statement and upon the failure of the medical evidence to throw any light upon the important question of homicide or suicide, the prisoner was discharged on a verdict of Not Proven. (Med. Times and Gazette, April 22 and May 20, 1854.)

It was proved by the two medical witnesses who gave evidence at the trial, that deceased had died from a pistol-shot, the bullet having penetrated the brain. From the characters of the wound, one thought that the muzzle of the pistol, when discharged, must have been within from three to twelve inches of the face. He admitted that, as an act of suicide, the body might have assumed the position in which it was found, but that the probabilities were against it. The other witness thought that the pistol, when discharged, might have been twelve or thirteen inches from the face; and although a person standing could, in his opinion have
made the wound that appeared on the cheek, yet a suicide would probably have made more sure of his aim, by selecting another position. The only information regarding the wound was, that it was in the right cheek, below the malar prominence; that the opening was blackened, and the nose scorched with gunpowder. It appears that the medical witnesses did not see the body until after the lapse of two days! It had in fact been removed from the spot, washed, dressed in grave-clothes, and put into a coffin, before they saw it. (Letter by Dr. Gordon, Med. Times and Gaz., May 20, 1854, p. 525.) Thus the marks of gunpowder on one of the hands, generally found in suicide by pistols, were not seen here; and the removal of the body from the spot placed the medical men in a difficulty, since they could base their opinions only on the statements of ignorant witnesses. There were marks of blood on the ground; but these, it was suggested, might have been accidentally caused during the removal of the body. The situation of the wound, i.e. below the malar prominence in the cheek, is rather unusual for an act of suicide; it was such as a murderer walking by the side of the deceased could have easily selected. The distance at which the pistol was held appears to have been greater than we find in cases of suicide; for had it been close, as it usually is in suicide, there would have been marks of extensive burning and laceration of the soft parts about the wound. The position of the pistol with respect to the body, as described by the witnesses who found it, is inconsistent with the supposition that deceased had thus fallen accidentally after having himself discharged the pistol. There was no motive for suicide, and no reason why, had suicide been contemplated, the deceased should have selected the prisoner's field for perpetrating the act. Deceased had been seen transacting business within half an hour of the time at which he must have died; and it was stated by his friends that they had never seen him with a gun or pistol in his possession, and had never known him to use firearms. Every fact, medical and moral, tended to prove that this was an act of homicide, and not one of suicide: further, there was no mark of struggling or scuffling, and no robbery had been perpetrated. The motive suggested by the prosecution against the prisoner, was based on the fact that he had effected insurances to the amount of about two thousand pounds, in three different offices, upon the life of the deceased, in whose life, however, he had no pecuniary interest. The insurances were for short periods; and it appears to be the practice in the Scotch offices that the policy is not rendered void by the act of suicide. It is important to state, as a supposed motive for the act, that the risk connected with the largest insurance (for one thousand pounds) commenced on the 24th November 1852, and terminated on the 24th November 1853. Only one premium to the amount of about eleven pounds had been paid, and, as it was proved, by
ACCIDENTAL GUN-SHOT WOUNDS.

the prisoner Smith. The deceased was found dead on the 20th November, i.e. only four days before the date at which the policy of insurance on his life would have lapsed. The accused had thus the motive, means, and opportunity of committing the crime, but there were no circumstances which could directly connect him with it. The early interference with the body, and the neglect to call for a medical investigation, probably led to the obliteration of parts of the evidence which would have clearly satisfied the jury that this could not have been an act of suicide.

Accidental gun-shot wounds bear the characters of near wounds:—they may touch vital parts, but, if the body be not disturbed, the presence or absence of design in the infliction of the wound is commonly made apparent by the relative position of the body and the weapon. They frequently arise from persons drawing the charges of guns or pistols with the muzzles pointed towards them, and they are then situated in front:—at other times they are produced by persons pulling towards them through a hedge, or dragging after them, a loaded gun. In the latter case the wound is behind, and strongly resembles a homicidal wound, although the circumstances under which the body is found generally suffice to explain the matter. In the following case of attempted suicide, the characters of the wound somewhat resembled those which are commonly imputed to homicide. In March 1844, a man was brought to Guy's Hospital, with a large ragged gun-shot wound on the right side of the head, behind the angle of the jaw, and between it and the ear. No slugs or bullets could be found; the direction was from behind forwards, and from above downwards. According to this man's statement, the pistol missed fire three times, but he succeeded in discharging it into his mouth at the fourth attempt. He lost a large quantity of blood, but after some time he walked to a table at the distance of five yards, reloaded the pistol, and discharged it at the back of his head in the situation described. Thus, then, there were in this case two wounds, one of them being apparently homicidal in its characters: and there was a power of locomotion after the first wound, in spite of great loss of blood. A gun-shot wound in the mouth or temple would seldom be set down to accident, and yet attempts are occasionally made to ascribe to such wounds an accidental origin. The admission of a near wound in the temple occurring from accident, must depend entirely upon the circumstances proved. (See the case of Reg. v. Tottenham, Norwich Lent Assizes, 1843.)

Position of the wounded person when shot.—Did the deceased receive the shot while standing, falling, or lying down? Was the piece, when discharged, pointed from the shoulder?—These questions can only be answered by reference to the particular circumstances of the case. In general, when a person is shot
WOUNDS FROM SMALL-SHOT.

while standing, and the piece is pointed from the shoulder, the wound is more or less transverse; but due allowance must be made for the deflection of balls after penetration. (The Queen v. Magarity, Central Criminal Court, July 1841.)

Was the deceased shot while running away, or when approaching the person who fired? — This question is answered by observing in the case of a traversing wound, in which alone any difficulty can arise, whether the entrance-orifice be situated in front or behind. A trial took place at the Kent Assizes, some years since, in which this question was material.

Wounds from small-shot.—Death is sometimes occasioned by small-shot, and here several medico-legal questions present themselves. Small-shot may act in two ways:—1, it either strikes without spreading, in which case the discharge is always near the person, and its action is much more dangerous than that of a single ball, because it produces extensive lacerations; or 2d, it strikes after it has spread, and here the discharge must have been distant, and comparatively little mischief is done. Dr. Lachêse ascertained, by many experiments on dead bodies, that in order to produce with small shot, a round opening, somewhat resembling that produced by a bullet, the discharge should take place point-blank at the distance of about ten or twelve inches from the surface of the body. When the distance was from twelve to eighteen inches, the opening made was irregular, and the borders were much lacerated; at thirty-six inches, a central opening was entirely lost, and the surface of the body was covered by shot. The effect after this was found to depend on the distance, the goodness of the gun, and the strength of the charge (Ann. d'Hyg. 1836, p. 386): but the shot is in general much scattered over the surface of the body. In this way we may form an opinion of the distance at which the piece was fired. In the case of the Queen v. Chapman (Oxford Lent Assizes, 1839), it was proved that the deceased had been killed by small-shot fired from a gun; that the discharge must have taken place very near, as the shot had not been scattered, and the point of the gun must have been below the level of the wound, as the direction was rather upwards. Two medical witnesses were examined, and both agreed that, judging from the direction of the wound, the gun, when fired, could not have been pointed from the shoulder. A similar question was raised in the case of Reg. v. Hull (Oxford Summer Ass. 1846), and it was decided that the discharge of the gun took place accidentally during a struggle. The case of the Queen v. Kendrew (York Winter Assizes, 1844) is in this respect of some medico-legal importance. The medical evidence was very satisfactory. It was shown to be highly improbable that deceased could have shot himself with small-shot from a gun, as the shot were scattered, and there was no round opening or mark of burning. It is difficult to conceive that small-shot can, under
any circumstances, produce a single entrance-wound, having some appearance of circularity about it, without at the same time singeing or burning the skin or dress.

Admitting the correctness of the inferences drawn by Dr. Lachèse, from the results of his experiments in discharging small-shot at dead bodies placed at different distances, it does not seem probable that a wound from small-shot can, under any circumstances, be mistaken for one produced by a leaden bullet. This question, however, arose in a case tried before Baron Parke (Rey. v. Spriggs, Lewes Lent Assizes, 1854), in which the prisoner was charged, upon his own statement, with having caused the death of his wife by discharging at her a loaded gun. When seen shortly after by the medical witness, deceased was quite dead. There was a "jagged" wound upon her forehead, about an inch above the right eyebrow. The witness described it as a wound which, from its appearance, might have been produced by any blunt instrument, or by a gun fired from a very short distance. On further examination it was found that the back part of the head had been driven in (?), and it appeared as though the shot had passed completely through the head and brain, passing out behind in a direction slanting downwards, the wound behind being three inches lower than that in front. He did not see any shot, nor did he open the head to endeavour to find any; but a portion of the skull and hair had been driven into the wound. The learned judge properly suggested that the brain should have been examined, as some shot might have remained there; and this would have shown exactly how the mortal injury was produced. The medical witness was pressed to say whether he was certain the injury had been caused by shot, and not by a bullet. He said he was certain it was by shot, as he had had much experience on bullet wounds in Ireland! Fortunately, there was good evidence to show that one barrel of the prisoner's gun had been discharged, and the undischarged barrel was found loaded with shot. The prisoner was convicted. There appears to have been no indication of burning or singeing of the hair or dress in this case, or the witness would not have suggested that the wound might have been occasioned by a blunt instrument. Considering that there were two penetrating wounds on opposite sides of the head, this was a singular part of the evidence. It is clear that there was one great central wound (the entrance-wound), which, although described as "jagged," appeared difficult to be accounted for, as no shot were scattered or could be found on the skin. Yet this single wound was obviously caused by small-shot. In all similar cases, it would be proper to examine the track of the wound throughout. According to Lachèse's experiments it is probable that the piece was in this case discharged at from twelve to eighteen inches from the surface of the skin.

A discharge of small-shot in contact with the skin or close to
it, will, however, produce not a round opening, but a severe lacerated wound. In the case of a gentleman of the Scotch bar (now on the bench), an accidental gun-shot wound in the leg occurred under the following circumstances. He had, during a sporting excursion, lain down on the grass and fallen asleep, the muzzle of his gun being close to the back of the calf of his left leg, and pointing in a slanting direction downwards. By some accident the gun went off, and the shot produced a complete laceration of the whole of the fleshly part of the leg, with no appearance of a round perforation. As might be expected from the closeness of the discharge, the leg of the trousers was much burnt, as well as cut and torn. Although, according to Dr. Lachèse's experiments, a round opening may be produced by small-shot when the piece is fired at the distance of a foot from the body, the above case clearly proves that the shot may be scattered, and an extensively lacerated wound caused, when the muzzle is close to the skin, and the piece is not discharged point-blank. The scattering of the shot, however, in such a case, could not lead to the inference that the discharge had taken place from a distance, because the skin and dress would always present distinct marks of burning.

Small-shot is rarely observed to traverse the body entirely unless discharged so near as to make a clean round opening; but a single pellet reaching the body may destroy life. Two cases have already been mentioned: one in which a young man was killed by a single pellet wounding the fifth intercostal artery; the other, in which a girl was killed by a pellet traversing the orbitar plate and wounding the brain. Such minute wounds might be easily overlooked in an examination of the body. Small-shot, even when wounding only the skin of the back very superficially, has been known to cause death by tetanus.

Wounds from wadding and gunpowder. — It matters not with what the piece is charged, — it is capable, when fired near, of producing a wound which may prove fatal. Thus a gun loaded with wadding, or even with gunpowder only, may cause death. In these cases, an impulsive force is given by the explosion, and the substance becomes a dangerous projectile. The lighter the projectile, the shorter the distance to which it is carried; but when discharged near to the body, it may produce a fatal penetrating wound. A portion of the dress may be carried into the wound, and lead to death from bleeding: or if the wounded person recover from the first effects, he may subsequently sink under an attack of tetanus or erysipelas. It is unfortunate that so much ignorance prevails on this point: for fatal accidents are continually occurring from persons discharging guns at others in sport, — an act which they think they may perform without danger, because they are not loaded with ball or shot. In the case of the Queen v. Race (Bury Lent Assizes, March 1840),
it was proved that the prisoner had killed the deceased by discharging at him, within a few feet, a gun loaded with powder and paper-wadding. The deceased fell, and died in a few minutes. It was found that the chest was penetrated, and that the wadding had wounded the left auricle of the heart.

It has been observed, that persons in attempting to committing suicide, have occasionally forgotten to put a bullet into the pistol; nevertheless, the discharge of a piece into the mouth has sufficed, from the effect of the wadding only, to produce a considerable destruction of parts, and to cause serious hæmorrhage. Fatal accidents have frequently taken place from the discharge of wadding from cannon during reviews. It is not easy to say at what distance a weapon thus charged with wadding and powder would cease to produce mischief, since this must depend on the impulsive force given by the powder, and on the size of the piece. Dr. Lachèse has ascertained by experiment, that a piece charged with gunpowder is capable of producing a penetrating wound somewhat resembling that caused by small-shot, when the piece is large, strongly charged, and fired within six inches of the surface of the body. (Ann. d'Hyg. 1836, 386.) This arises from a portion of the powder always escaping combustion at the time of discharge, and each grain then acts like a pellet of small-shot. Under any circumstances, a discharge of powder only, contuses the skin, producing ecchymosis, and often lacerating it, if the piece be fired near. The dress is burnt and the skin scorched from the globe of flame formed by the combustion of the powder; many particles of gunpowder may be actually driven into the true skin. All the substances here spoken of are considered to be projectiles; and the weapons are held in law to be loaded arms, so long as they are capable of producing bodily injury at the distance from which the piece containing them is discharged. It may therefore become a question as to the distance at which these light projectiles cease to be harmless. The answer must be governed by circumstances; but it will in all cases materially depend on the strength of the charge. In the case of Reg. v. Collier (Ablingdon Lent Assizes, 1844), the prisoner was charged with firing a gun loaded with small-shot at the prosecutor, with intent to do grievous bodily harm. It appeared that the gun was deliberately pointed at the prosecutor, who was then at a distance of from seventy to eighty yards from the prisoner. The shot, which was very small, had marked the clothes, but had not penetrated the skin or inflicted any wound. The defence was, that, from the slight injury done, the prisoner merely intended to frighten the prosecutor, and not to do him any bodily harm. He was found guilty of a common assault. The question was here a delicate one, for had the prosecutor been a few yards nearer, and the pellets touched an exposed part of the body, the result might have been serious. One pellet has destroyed life (ante,
IDENTITY FROM THE FLASH OF POWDER.

p. 398). A case occurred, in the United States, involving the question, as to the distance at which a pistol not loaded with ball, would suffice to produce a serious wound. A boy, in play, discharged a pistol at a companion, producing on the fleshy part of the left hip a wound one inch in diameter and four inches in depth. The skin was destroyed, and the muscles presented a blackened lacerated mass. There was no ball in the pistol; but it is not certain whether there was wadding. Death took place from tetanus on the seventh day; and on examination, no wadding was found in the wound. There were, however, grains of gunpowder, with which the wound was blackened throughout its whole extent. At the inquest the witnesses differed respecting the distance at which the pistol was held when the wound was inflicted. Some said one foot; others two or three yards. The deceased stated his belief that the pistol almost touched him; and, judging by the state of the wounded parts, this was probably the truth. Dr. Swift believed that the wound had been produced by gunpowder only, without wadding. He performed some experiments with the pistol used by the prisoner, but loaded with gunpowder and wadding, in order to determine the effect of discharges at different distances. At twelve inches distance from a body, he found that the clothes were lacerated and the skin abraded, but the wadding did not penetrate; at six inches, the clothes were lacerated, and the wadding penetrated to the depth of half an inch; at two inches, the wound produced, which was two inches deep, was ragged and blackened; at one-and-a-half inch from the chest, the wadding passed into the cavity between the ribs, and in a second experiment it carried away a portion of a rib. (Med. Gaz. xl. 784.) These results confirm those obtained by Dr. Lachèse (ante, p. 396).

Identity from the flash of powder. — Among the singular questions which have arisen out of this subject, is the following: — Whether a person who fires a gun or pistol at another during a dark night, can be identified by means of the light produced in the discharge? This question was first referred to the class of Physical Sciences in France, in 1809, and they answered it in the negative. A case tending to show that their decision was erroneous, was subsequently reported by Foderé. A woman positively swore that she saw the face of a person, who fired at another during the night, surrounded by a kind of glory, and that she was thereby enabled to identify the accused. This statement was confirmed by the deposition of the wounded party. Desgranges, of Lyons, performed many experiments on this subject; and he concluded that on a very dark night, and in the absence of every other source of light, the person who fired the gun might be identified within a moderate distance. If the flash were very strong, the smoke very dense, and the distance great, the person firing the piece could not be identified. The question was raised
in this country, in the case of the *Queen v. White*, at the Croydon Autumn Assizes, 1889. A gentleman was shot at, while driving home in his gig during a dark night; he was wounded in the elbow. When he observed the flash of the gun, he saw that it was levelled towards him, and the light of the flash enabled him to recognise at once the features of the accused:—in cross-examination he said he was quite sure he could see him, and that he was not mistaken as to his identity. The accused was skilfully defended, and he was acquitted. Evidence of this kind has, however, been received in an English Court of Law. A case is quoted by Paris and Fonblanque (*Rex v. Haines*), in which some police-officers were shot at by a highwayman during a dark night. One of the officers stated that he could distinctly see, from the flash of the pistol, that the robber rode a dark-brown horse of a remarkable shape in the head and shoulders; and that he had since identified the horse at a stable in London. He also perceived, by the same flash of light, that the person had on a rough brown great coat. This evidence was considered to be satisfactory.

From the information which I have been able to collect on this point it appears to me there can be no doubt, that an assailant may be thus occasionally identified. It is widely different, however, in respect to the following case referred to by Müller, in his Physiology; namely, where a man declared that he recognised a robber through the light produced by a blow on his eye in the dark! As Müller observes, this is a clear impossibility; because the flashes thus perceived are unattended with the emission of light, and therefore can never be visible to any other person than the subject of them, and it is not possible that they can ever make other objects visible. [For some remarks on this subject by Dr. Schilbach, see Henke’s *Zeitschrift der S. A.* 1842, i. 197.] Dr. Krügelstein has lately opposed the inference deduced by Müller, and has supported his views by cases, which, however, do not appear to me to be satisfactory. (Henke’s *Zeitschrift der S. A.* 1845, iii. 172.)

**Chemical examination of fire-arms.**—An attempt has been made by French medical jurists, to determine for how long a period a gun or a pistol found lying near a dead body may have been discharged; but it is out of our power to lay down any precise rules on such a subject. All that we can say is, a quantity of sulphuret of potassium, mixed with charcoal, is left adhering about the barrel of the piece, when recently discharged; and this is indicated by its forming a strong alkaline solution with water, evolving an odour of sulphuretted hydrogen, and giving a deep brown precipitate with a solution of acetate of lead. After some hours or days, according to the degree of exposure to air and moisture, the saline residue becomes converted to sulphate of potash, forming a neutral solution with water, and giving a white precipitate.
with acetate of lead. If a considerable time has elapsed since the piece was discharged, oxide of iron with traces of sulphate may be found. (See Ann. d’Hyg. 1834, 454; 1839, 197; 1842, 368.) This subject has excited some attention on certain trials which have taken place in France in reference to the death of M. Dujarrier. It was considered here of some importance to determine whether, by the mere discharge of powder, such a deposit of charcoal or powder took place at the mouth of the pistol, as to soil the finger when introduced three hours after the alleged discharge. M. Boutigny conducted the investigation, and found in his experiments that the finger was not blackened under the circumstances. He considers that sulphate and carbonate of potash are formed, and that the charcoal is entirely consumed. The facts proved at the trial were, however, adverse to the view thus taken; and it really appears that this most elaborate inquiry, involving physics, chemistry, and mathematics, might have been spared, on the simple ground that the result produced by a discharge of powder in the way supposed, must depend on the quantity of powder employed (its perfect or imperfect combustion), and the proportion of charcoal contained in it! The elements for solving this pyrotechnic question must therefore in most, if not in all cases, be wanting. (Ann. d’Hygiène, 1848, i. 392.)

PROJECTILES.—In the case of Rush, who was tried and convicted of the murder of Mr. Jermy, by a remarkable train of circumstantial evidence (Norwich Lent Assizes, 1849), it was proved that the projectiles removed from the body of the deceased consisted of irregular pieces of lead (slugs). Similar masses were taken from the body of the son, who was killed at the same time. They were described by the medical witness as being angular, and quite unlike the shot used in killing game. Each piece weighed from eleven to thirteen grains, and there were fifteen pieces in all. As the learned judge remarked, this demonstrated that the two acts of murder were committed by the same person, or by this person acting in concert with others. In the case of the Queen v. Lloyd (Shrewsbury Lent Assizes, 1854), it was proved that deceased had been killed by the discharge of a gun through a window. He was struck on the head by about thirty shots, one of which had penetrated the brain and caused death. The assailant was not seen, but the charge was brought home to him by numerous circumstances: among others, by the discovery, in one of his pockets, of shot of the same sizes as those removed from the head of deceased (Nos. 3 and 4). The surgeon had very properly removed and preserved the shot, so that they were afterwards available as evidence against the prisoner.

The chemical analysis of a projectile may be occasionally necessary. A common bullet is entirely formed of lead. Cast bullets are very commonly found to have a void space in the in-
CHAPTER XXXVII

BURNS AND SCALDS—CIRCUMSTANCES WHICH RENDER THEM DANGEROUS TO LIFE—DID THE BURNING TAKE PLACE BEFORE OR AFTER DEATH?—EXPERIMENTS ON THE DEAD BODY—VESICATION AND LINE OF REDNESS—PRESENCE OF SEVERAL BURNS—WOUNDS CAUSED BY FIRE—HUMAN OR SPONTANEOUS COMBUSTION—HOMICIDAL MISTAKEN FOR SPONTANEOUS COMBUSTION. TIME REQUIRED FOR THE BURNING OF A DEAD BODY—BURNS BY CORROSIVE LIQUIDS.

BURNS AND SCALDS.

A *Burn* is an injury produced by the application of a heated substance to the surface of the body; while a *Scald* results from the application of a liquid at or near its boiling point, under the same circumstances. There seems to be no real distinction between a burn and a scald as to the effects produced on the body:—the injury resulting from boiling mercury or melted lead might take either appellation. Nevertheless, as a matter of medical evidence, it may be important to state whether the injury found on a body was caused by such a liquid as boiling water, or by a heated solid. If the former, the injury might be ascribed to accident; if the latter, to criminal design. A scald produced by boiling water would be indicated by a sodden state of the skin, and there would be no loss of substance. In a burn by a heated solid, the parts may be more or less destroyed, or even charred: the cuticle may be found blackened, dry, almost of a horned consistency, and presenting a shrivelled appearance. This means of diagnosis would only apply to scalds from water. A scald from melted lead could not be distinguished from a burn produced by a solid heated to the same temperature. Some of the oils boil at
500°, and produce, by contact with the skin, burns as severe as those caused by melted metals.

Action of melted metals.—A singular case in which an attempt on life was made by pouring a melted metal into the ear, occurred to M. Boys de Loury. The mother of an idiot, aged twenty-five, wishing to get rid of him, adopted the plan of pouring melted pewter into his right ear while he was lying asleep. Great pain and violent inflammation followed, but the young man recovered. The mother then alleged that he had himself poured the melted metal into his ear. At a judicial investigation, M. Boys de Loury was required to say whether such an act was likely to occasion death, and if so, how it happened at the party had in this instance recovered. The alloy was formed of seven parts of tin and three of lead, and the melting point of such an alloy would be about 340°. M. de Loury stated that such an act might lead to death by causing inflammation and caries of the internal ear extending to the brain. The recovery of the youth was owing to the mischief which followed having been comparatively slight. In performing some experiments on the dead body, he found that it was difficult to fill the ear-passage with such an alloy, in consequence of the sudden expansion of the air caused by the high temperature. (Ann. d'Hyg. 1847, ii. 424.)

Various degrees of burns.—Dupuytren has divided burns into six degrees, which are commonly recognised by medical jurists.

1. The heat produces a simple inflammation of the skin without vesication. The skin is very red, but the redness disappears on pressure: there is slight and superficial swelling, with severe pain, relieved by the contact of cold substances. The inflammation subsides after a few hours, and the skin resumes its natural condition:—or it may continue for several days, and the cuticle then peels off.

2. There is a severe inflammation of the skin, and the cuticle is raised into blisters containing a yellow-coloured serum. This kind of injury is generally the result of the action of boiling liquida. The blisters are commonly formed immediately; and others are produced during a period of twenty-four hours, or those which are already formed become enlarged. Suppuration takes place if the cuticle be removed, and the person survives for a period sufficiently long. As the cutis or true skin is not destroyed by this degree of burn, there is no mark or cicatrix to indicate its past existence.

3. The superficial part of the cutis is destroyed. The burn appears in the form of yellow or brown patches, insensible when gently touched, but giving pain when strongly pressed. An inflammatory redness, accompanied by vesication or blistering, is perceived in the healthy portion of skin around the escars. A white and shining cicatrix, without contraction of parts, remains after healing. This degree of injury is commonly observed
in burns from gunpowder, and the part which was the seat of the burn is frequently stained black, when the particles of gunpowder have not been removed soon after the accident.

4. The skin is disorganised as far as the subcutaneous cellular tissue. There are firm and thick eschars, which are quite insensible. If the burn has arisen from a boiling liquid, the eschars are soft and of a yellowish colour; if from a red-hot solid, they are firm, hard, of a brown colour—sometimes black. The skin around appears shrivelled and puckered towards the eschar, which is depressed below the cutaneous surface. The surrounding integuments present a high degree of inflammation; and vesications appear. From the fourth to the sixth day, the eschar falls off, leaving an ulcerated surface, which heals slowly, and is always indicated by a cicatrix.

5. In the fifth degree, the whole of the layers of the skin, the cellular membrane, and a portion of the muscles beneath, are converted into an eschar. The appearances are similar to those of the fourth degree, but in a more aggravated form.

6. The burnt part is completely carbonized. If the individual survives, the most violent inflammation is set up in the subjacent tissues and organs.

Danger to life.—Neither a burn nor a scald appears to be considered as a wound in law; but in the statute of wounding they are included among bodily injuries dangerous to life. (1 Vict. 85, sec. ii.) Burns and scalds are dangerous to life in proportion to the extent of surface which they cover, as well as the depth to which they extend. The extent of surface involved in a superficial burn is of greater moment than the entire destruction of a small part of the body through an intensely heated solid. When the burn is extensive, death may ensue either from the intensity of the pain produced, or from a sympathetic shock to the nervous system. Death takes place rapidly from burns in children and nervous females; but in adults and old persons, there is a better chance of recovery. When death has been caused by intense pain, no changes have been detected after death; but under other circumstances, it has been found on inspection that there were patches of redness on the bronchial mucous membrane, as well as on that of the alimentary canal. The brain has been found gorged, and the ventricles have contained an abundance of serosity. The serous liquids of the pericardium and pleura have also been in larger quantity than natural. In short, besides congestion, there is generally abundant serous effusion in one of the three great cavities, especially in the cranium. This arises from the sudden reflux of blood into the interior. (See case by Mr. Long, Med. Gaz. xxv. p. 743; also, by Mr. Erichsen, xxxi. p. 551.) If the person survive the first effects, he may die from inflammation, suppuration, gangrene, irritation, fever, or he may be worn out by exhaustion. In this respect,
burns of the 4th, 5th, and 6th degrees are especially dangerous to life; and it would be unsafe to give an early opinion, as inflammation of deep-seated viscera only appears after several days.

Stupor from burns. — In some instances, especially in children, stupor and insensibility have supervened, owing to a sympathy with the brain; and these symptoms have been followed by coma and death. If, under these circumstances, opium has been given to the patient as a sedative, the stupor resulting from the burn may be attributed to the effects of the drug; and should the person die, the practitioner may find himself involved in a charge of malapraz. It may be alleged, as in the following case related by Mr. Abernethy, that the person was poisoned by opium. A medical man was charged with the manslaughter of a child by giving to it an overdose of opium, when it was labouring under the effects of a severe scald. Mr. Abernethy stated in his evidence, which was given in favour of the practitioner, that he thought the exhibition of opium very proper: — that the quantity given, eight drops of tincture of opium immediately after the accident, and ten drops two hours afterwards, was not an overdose for a child (the age is not stated). The circumstance of the child continuing to sleep until it died, after the exhibition of the opium, was no proof that it had been poisoned. This sleep was nothing more than the torpor into which it had been plunged by the accident. The surgeon was acquitted. Notwithstanding the favourable opinion expressed of this plan of treatment, it would be advisable to avoid the use of opium on these occasions in respect to infants and young children. Life is readily destroyed in young subjects by the smallest doses of this drug; and there are no satisfactory means of distinguishing the comatose symptoms produced by a burn or scald, from those produced by an overdose of opium.

Did the burning take place before or after death? Vesication.— The production of vesication or of blisters containing serum, is commonly regarded as an essential character of a burn which has been produced during life. Vesication is especially seen in scalds, or in those cases in which the skin has been burnt by flame or by the ignition of the clothes, provided the cuticle be not destroyed. It is not so commonly observed in burns produced by intensely heated solids. In vesication, the cuticle is raised from the true skin beneath, and is converted into one or more blisters containing serum, while the skin around is of a deep-red colour. It is very uncertain as to the time at which it appears; it may be produced in a few minutes, or sometimes not for several hours: thus, death may take place before vesication occurs; and the non-discovery of this condition does not warrant the opinion that the burn could not have taken place during life. If the cuticle be removed from a vesicated part of the living body, the skin beneath will become intensely red-
EVIDENCE FROM VESICATIONS OR BLISTERS. 407
denied; but if the cuticle be stripped off in a dead subject, the skin will become hard, dry, and of a horny-yellow colour; it does not acquire the intense scarlet injection which is acquired by the living skin under the same circumstances.

Vesication as an effect of dry heat.—There have been conflicting opinions whether the presence of blisters (vesication) on a dead body should be taken as evidence of burning during life. The following may be taken as a summary of the facts hitherto ascertained. Dr. Christison, on one occasion, had an opportunity of trying experiments on the effects of dry heat on the same body before and after death; this was in the case of a young man who had poisoned himself with opium. While he was lying in a hopeless state of coma, four hours before death, a hot iron was held on the outside of the hip-joint; and half an hour after death, a red-hot poker was applied to three places on the inside of the arm. Vesication followed the burns in both instances; but those caused during life contained serum, and those formed after death, air. In another experiment, a cauterizing iron produced no blisters on a leg, half an hour after amputation; but vesications, containing air, were formed, when in another case the iron was applied ten minutes after amputation. On the whole, Dr. Christison thinks that a vesication containing serum, indicates a burn during life, and one containing air, a burn after death. I have performed some experiments on the bodies of infants eighteen and twenty hours after death, both with boiling water and heated solids; but in no case have I observed any kind of vesication to follow at that period. The skin was shrivelled, and was partly destroyed by the heat, but there were no blisters produced. (See case by M. Ollivier, Ann. d’Hyg. 1843, i. 383.) It has been ascertained, that under certain morbid states of the body, blisters containing serum may be produced in the dead body, even twenty-four hours after death. M. Leuret observed, that this took place in an anasarcaous subject, in the vicinity of which a heated brazier had been placed. The cuticle was hardened, then raised and blistered; and the blister contained an abundance of reddish-coloured serum. In repeating this experiment on other dead bodies not infiltrated, it was observed that no vesications containing serum were produced. (Ann. d’Hyg. 1835, ii. 387.) M. Champonillon has recently repeated the experiments of M. Leuret on anasarcaous bodies, and he finds that blisters may be produced in these cases at almost any period after death. Thus, they occurred when heat was applied to the anasarcaous subject recently dead,—to another when in a state of cadaveric rigidity, and to a third when putrefaction had commenced. The blisters do not appear immediately,—the time which he found requisite for their production varied from two to six hours. The serum effused beneath the raised cuticle was rarely tinged with blood. (Ann. d’Hyg. 1846, i. 421.) These experiments only
confirm the results obtained by M. Leuret; they add nothing to our knowledge of the subject. The conclusion to be drawn from them is, that in the examination of burns on the body of a person affected with anasarca, it is necessary to be cautious in expressing an opinion. In such cases it would not be possible, from the existence of mere vesication, to say whether the burn took place before or after death.

The late Dr. Wright, of Birmingham, has published the results of some experiments on burning after death, from which he infers that the production of a serous blister in the dead body is not dependent on the presence of serum in the cellular tissue (anasarca), but upon the amount of (latent) organic life remaining in the body. He states that he has produced a serous blister in a dead body more than a dozen times,—twice within half an hour, and once within fifteen minutes after death; and in amputated limbs he has produced them in from half a minute to four minutes and a half after amputation. The only favourable opportunity which occurred to him for producing, after death, a serous blister, was in the person of a female thirty years of age, who died suffocated from acute congestion of the lungs. She was slightly anasarcaous. Three hours and a half after death, when the body was quite warm, and the joints flexible, a spirit-lamp flame was applied to the lower and back part of the left leg. After the lapse of an hour, blisters had arisen filled with serum of a pale straw colour: one contained two and the other three drachms. Ten and fifteen hours after death, when the body had become cold and rigid, the flame produced only gaseous blisters. (Pathological Researches on Vital and Post-mortem Burning, 1850.)

Vesication as a result of scalding in the dead body.—Dr. Christison found that when boiling water was poured upon a dead body ten minutes after death, the skin was simply ruffled and shrivelled; but the cuticle was not raised into a blister. The same effects were produced so long as a body retained its warmth. Accident has enabled me to state the result within a shorter period than that above-mentioned. The body of a drowned man, within a few minutes of the accident, was removed and placed in a warm (hot?) bath. It was found impossible to resuscitate him, but owing to the great heat of the water, portions of the cuticle came off, when the body was removed. On inspection there were several vesications filled with bloody serum over a considerable portion of the skin, especially of the extremities. There was no anasarca here to account for their production; and the fact of their occurrence appears to bear out the view of Dr. Wright, that the production of a serous blister on the dead body depends on the amount of latent organic life remaining in the body. The man was pulseless, and to all appearance dead, when placed in the hot bath; hence the effects of hot liquids
on the living and the recently dead body are proved by this case to be similar.

A line of redness.—In burns produced by red-hot solids, other effects besides vesication follow. The edge of the skin immediately around the part burnt is commonly of a dead white; and close to this is a deep red line, gradually shaded off into the surrounding skin, which is reddened. The diffused redness is removable by pressure, and disappears with life; the red line here referred to, however, is not removable by pressure, and is persistent after death. This line of redness is not always met with in severe burns; and when the individual survives one or two days, its production appears to depend upon a power of reaction in the system. Thus, then, its absence furnishes no proof of the burn having been produced after death; for it is not a necessary accompaniment of a burn during life. Dr. Christison has endeavoured to determine by experiment whether this line of redness could be produced by applying a heated solid to a dead subject. He found that when the person had been dead only ten minutes, no such effect was produced. In repeating his experiments on dead subjects many hours after death, I have found that no line of redness ever presented itself; so that its discovery in a dead body burnt, would appear to indicate either that the burning took place during life, or within ten minutes after death,—most probably the former. M. Champouillon takes exception to the inference derivable from these experiments. He says that he has caused the production of a line of redness by the application of heat to the dead body, and that it is a uniform accompaniment of the formation of blisters in the dead. He admits that it is in this case a mere capillary infiltration, quite superficial, and surrounding the margin of the blister, while in the red line produced during life, the tissues of the skin are deeply injected, and it is evidently the result of vital reaction. (See Ann. d’Hyg. i. 422.) It would appear that he has only remarked this condition in dead anasarcan bodies, in which vesications had been produced, and it is obvious from the description, that he is referring to a slight congestion of the vessels, occasioned probably by the stagnation of the fluid portion of the blood in the superficial capillaries. It is altogether distinct from the line of redness described by Dr. Christison as a frequent consequence of severe burns. In the case of Mr. Westwood, who was murdered in June 1839, the fact of certain burns found on the body having been produced during life, was determined by Mr. J. G. French, from an observance of this sign. The deceased was found dead, with his skull extensively fractured, his throat cut, and his body burnt in various places. Mr. French, who gave evidence on this occasion, remarked, that the burns were surrounded by a line of redness:—that they were probably produced about the same time as the other injuries, but certainly
while there was some vital action in the system. When, however, vesication and a line of redness are absent, we have no medical data on which to found an opinion as to whether the burn was caused before or after death. Dr. Wright considers that in a low state of vitality a line of redness might not be produced by a severe burn on the living body, and that more certain reliance may be placed on the red marks found beneath the blisters and crusts of vital burns. These latter have been well-marked when he has found the line of redness itself indistinct. (Op. cit. page 25.) These remarks of Dr. Wright were chiefly made in reference to a remarkable case of alleged matricide at Bridgnorth. (Reg. v. Newton, Shrewsbury Lent and Summer Assizes, 1849.)

When several burns are found on a dead body, it may be a question whether they were all produced at the same time. This is a point which can be determined only by observing whether any of them present signs of gangrenous separation, of suppuration, granulation, or other changes that take place in a living body after accidents of this kind. The witness may be asked, how long did the deceased survive the burn? A person may die in a few minutes or live some hours after receiving a most extensive burn; and yet there will be no change in the part burnt, to indicate when death actually took place. There may have been no time for inflammation or its consequences to become established. Suppuration generally follows vesication, and in severe cases it may occur on the second or third day; but often not until a later period. In regard to gangrene, this takes place when the vitality of a part burned is destroyed. The time of its occurrence is uncertain, but it sometimes very speedily follows the accident.

After murder has been perpetrated, it is not uncommon for a murderer to attempt to dispose of the body by burning it. This was remarked in the case of Mr. Paas (King v. Cook), likewise in the case of the Queen v. Good, and in another case at Leeds (Jan. 1843), where a mutilated body was found floating in a river with marks of burning about it. In general, the body is not burnt until all signs of life have disappeared; we shall therefore meet, in such cases, with nothing but the charring of dead flesh, so that no difficulty can exist in forming an opinion. When the burning is partial, and has probably taken place from a wilful ignition of the clothes, at or about the time of death, some caution is required in expressing an opinion, since marks of vesication and a line of redness are not always present in burns during life. It is by no means unusual, however, to find it stated in evidence, that blisters are a constant accompaniment of a burn in the living body! In the case of the Queen v. Taylor (York Lent Assizes, 1842), the deceased was found dead with marks of strangulation on her neck, and her clothes were much burnt
from her waist to the knees. She was lying across the hearth, —the body was burnt as well as the upper and lower extremities and the neck; in the opinion of the medical witness, the burn on the neck could not have been produced by the fire extending from the other parts of the body. In cross-examination he stated that the burns must have occurred after death: they could not have taken place before, nor at the time of death, because there was no vesication, and he had never seen a burn on a living person which was not followed by blistering! The prisoner was convicted, the counsel having failed to prove or render it probable that death was caused as alleged by accidental burning. The reader will find some remarks on the burning of the living and dead body, in the report of the trial of Dr. Webster for the murder of Dr. Parkman. (See Report by Dr. Stone, Boston, 1850.)

Wounds caused by fire.—On the discovery of wounds on a body burnt by fire, it is necessary they should be closely examined, in order that a witness may be enabled to say whether they have been caused by cutting or other instruments, before death by burning, or whether they are not simple mechanical results of the effects of fire on the skin. Mr. Curling has communicated to me a case which will show the importance of this inquiry. A little boy, two years of age, was brought to the London Hospital, Nov. 11th, 1840, so severely burnt on the face, neck, abdomen and extremities, that he survived the accident only three quarters of an hour. It appeared that the stepmother, who had charge of the child, left him at home locked up in the room where there was a fire, while she went out. Some of the neighbours shortly afterwards hearing screams proceeding from the room, broke open the door, and discovered the child enveloped in flames, and its clothes on fire. The flames were immediately extinguished, and the little boy was brought to the hospital. Suspicion of unfair treatment having been excited by the appearance of wounds about the knees which were observed as soon as the child was admitted, and by the reported neglect and ill-usage of the child by the stepmother, the coroner directed an inspection to be made. The body was plump and well-formed. The skin in the burnt parts was denuded of cuticle and converted into a deep yellowish or blackish dry mass, which was very tense, hard, and easily torn. There were gaping wounds on both knees. On the right side, a fissure in the skin commenced about the middle of the thigh, and proceeded for two inches and three-quarters to the inside of the patella, where it became somewhat jagged, and making a sudden turn inwards passed to the extent of two inches towards the back of the joint. A transverse laceration of the skin, three-quarters of an inch in length, was observed on the front of the left thigh a little above the knee; and another, which was also transverse and measured an inch and a half, was situated below, on the inner side of the joint. These fissures in the charred
skin were all about three lines in width and two in depth, and exposed the adipose tissue beneath, which appeared white, and free from all appearance of effusion of blood. The edges of these fissures were not uneven, but they did not present the clean and smooth appearance usually observed in incised wounds. The vessels on the surface of the brain were very turgid, and the cortical structure appeared remarkably dark-coloured. The lungs were congested, but the heart contained very little blood. The mucous membrane of the stomach presented a slight pinkish hue, but that of the intestinal canal was nearly white. The follicles throughout the whole of the intestines were all highly developed and very prominent. The mesenteric glands were enlarged. The alimentary canal contained a good deal of undigested food. The liver was in every respect natural. From the absence of any trace of effusion of blood, the sound condition of the exposed adipose tissue, its exemption from the action of the fire, and the irregular character and appearance of the fissures, Mr. Curling concluded that they were not the result of wounds inflicted before the occurrence of the burn; he considered them to have been occasioned by the influence of heat, which had forcibly corrugated the skin and completely destroyed its elasticity, and the superficial layer of adipose tissue being closely adherent to the cutaneous tissue, necessarily gave way at the same time. In several places some small vessels containing blood were observed running across the fissures; these, being more tenacious than the adipose tissue, had not yielded with it. This appearance alone was sufficient to negative the supposition of the infliction of wounds by cutting instruments. The production of the fissures might have been aided by the child’s struggles immediately after the occurrence of the burn, but it did not appear that they were at all violent. The conclusion at which Mr. Curling arrived was quite justified by the facts; and the case is calculated to throw an important light on the accidental origin of fissures or wounds of the skin in cases of death from burns.

Summary.—The conclusions which, it appears to me, we may draw from the foregoing statements, are: 1, that, as a general rule, when we discover marks of vesication, with serous effusion, or a line of redness, or both, about a burnt part of the body, we are justified in saying that the burn has occurred during life; 2, that when these appearances are not met with, it by no means follows that the burn had not been produced in the living body; the affirmative evidence derived from such appearances being much stronger than the negative.

Cause of death.—Whether a burn or a scald was or was not sufficient to account for death, must be determined by the extent, depth, and situation of the injury; but even when the burn has clearly been caused during life, the body should be carefully
examined for other marks of violence, as blows upon the head, wounds, marks of strangulation, and internally for haemorrhage, disease, or poisoning. It must be remembered, that in burns which are rapidly fatal, the serous liquid found in the cavities has commonly a red colour, and the mucous membranes are also reddened.

The subject of scalding scarcely requires a separate notice. A scald from boiling water would, when recent, be indicated by vesication and the sodden state of the skin. The living structures are not charred or disorganised as by the application of a red-hot solid. At the Liverpool Summer Assizes, 1847, a woman was convicted of throwing boiling water over her husband, with intent to maim him. (Reg. v. King.) In another case (Reg. v. Blewitt, Worcester Summer Assizes, 1847), the prisoner was convicted of the manslaughter of his wife by pouring over her the contents of a kettle of boiling water. A woman at Glasgow attempted to kill her husband by pouring boiling water over his genital organs, while he was asleep in bed. He died, but his death could not be clearly traced to this cause. These are the only recent instances of criminal scalding which are reported.

HUMAN OR SPONTANEOUS COMBUSTION.

Supposing that a dead body is found burnt, and there is no other cause of death about it, it may be said that the burning was neither the result of accident nor of homicide, but that it was the effect of spontaneous or human combustion. There are two opinions concerning this so-called spontaneous destruction of the human body. On the one hand, it is alleged that the combustion may take place from internal causes,—in other words, that the process is literally spontaneous; on the other hand, it is contended that the contact of a substance in a state of ignition is necessary for the production of the phenomenon,—so that, according to this view, the human body merely becomes preternaturally combustible. The hypothesis of those who advocate spontaneous combustion, is, it appears to me, perfectly untenable. So far as I have been enabled to examine this subject, there is not a single well-authenticated instance of such an event:—in the cases reported which are worthy of any credit, a candle, or some other ignited body, has been at hand, and the accidental ignition of the clothes was highly probable, if not absolutely certain. It is in vain that they who adopt this hypothesis appeal to the electrical state of the atmosphere or of the individual, coupled with the impregnation of the system with the inflammable principles of alcohol, as conditions sufficiently explanatory of their views,—such explanations may be reserved until the occurrence of this spontaneous combustion from internal causes is placed beyond all dispute. [For a full description of the phenomena which are said to accompany this condition, see Casper's Wochenchrift,
skin were all about three lines in width and two in depth, and exposed the adipose tissue beneath, which appeared white, and free from all appearance of effusion of blood. The edges of these fissures were not uneven, but they did not present the clean and smooth appearance usually observed in incised wounds. The vessels on the surface of the brain were very turgid, and the cortical structure appeared remarkably dark-coloured. The lungs were congested, but the heart contained very little blood. The mucous membrane of the stomach presented a slight pinkish hue, but that of the intestinal canal was nearly white. The follicles throughout the whole of the intestines were all highly developed and very prominent. The mesenteric glands were enlarged. The alimentary canal contained a good deal of undigested food. The liver was in every respect natural. From the absence of any trace of effusion of blood, the sound condition of the exposed adipose tissue, its exemption from the action of the fire, and the irregular character and appearance of the fissures, Mr. Curling concluded that they were not the result of wounds inflicted before the occurrence of the burn; he considered them to have been occasioned by the influence of heat, which had forcibly corrugated the skin and completely destroyed its elasticity, and the superficial layer of adipose tissue being closely adherent to the cutaneous tissue, necessarily gave way at the same time. In several places some small vessels containing blood were observed running across the fissures; these, being more tenacious than the adipose tissue, had not yielded with it. This appearance alone was sufficient to negative the supposition of the infliction of wounds by cutting instruments. The production of the fissures might have been aided by the child's struggles immediately after the occurrence of the burn, but it did not appear that they were at all violent. The conclusion at which Mr. Curling arrived was quite justified by the facts; and the case is calculated to throw an important light on the accidental origin of fissures or wounds of the skin in cases of death from burns.

Summary.—The conclusions which, it appears to me, we may draw from the foregoing statements, are: 1, that, as a general rule, when we discover marks of vesication, with serous effusion, or a line of redness, or both, about a burnt part of the body, we are justified in saying that the burn has occurred during life; 2, that when these appearances are not met with, it by no means follows that the burn had not been produced in the living body; the affirmative evidence derived from such appearances being much stronger than the negative.

Cause of death.—Whether a burn or a scald was or was not sufficient to account for death, must be determined by the extent, depth, and situation of the injury; but even when the burn has clearly been caused during life, the body should be carefully
examined for other marks of violence, as blows upon the head, wounds, marks of strangulation, and internally for hemorrhage, disease, or poisoning. It must be remembered, that in burns which are rapidly fatal, the serous liquid found in the cavities has commonly a red colour, and the mucous membranes are also reddened.

The subject of scalding scarcely requires a separate notice. A scald from boiling water would, when recent, be indicated by vesication and the sodden state of the skin. The living structures are not charred or disorganised as by the application of a red-hot solid. At the Liverpool Summer Assizes, 1847, a woman was convicted of throwing boiling water over her husband, with intent to maim him. (Reg. v. King.) In another case (Reg. v. Blewitt, Worcester Summer Assizes, 1847), the prisoner was convicted of the manslaughter of his wife by pouring over her the contents of a kettle of boiling water. A woman at Glasgow attempted to kill her husband by pouring boiling water over his genital organs, while he was asleep in bed. He died, but his death could not be clearly traced to this cause. These are the only recent instances of criminal scalding which are reported.

HUMAN OR SPONTANEOUS COMBUSTION.

Supposing that a dead body is found burnt, and there is no other cause of death about it, it may be said that the burning was neither the result of accident nor of homicide, but that it was the effect of spontaneous or human combustion. There are two opinions concerning this so-called spontaneous destruction of the human body. On the one hand, it is alleged that the combustion may take place from internal causes,—in other words, that the process is literally spontaneous; on the other hand, it is contended that the contact of a substance in a state of ignition is necessary for the production of the phenomenon,—so that, according to this view, the human body merely becomes preternaturally combustible. The hypothesis of those who advocate spontaneous combustion, is, it appears to me, perfectly untenable. So far as I have been enabled to examine this subject, there is not a single well-authenticated instance of such an event:—in the cases reported which are worthy of any credit, a candle, or some other ignited body, has been at hand, and the accidental ignition of the clothes was highly probable, if not absolutely certain. It is in vain that they who adopt this hypothesis appeal to the electrical state of the atmosphere or of the individual, coupled with the impregnation of the system with the inflammable principles of alcohol, as conditions sufficiently explanatory of their views,—such explanations may be reserved until the occurrence of this spontaneous combustion from internal causes is placed beyond all dispute. [For a full description of the phenomena which are said to accompany this condition, see Casper's Wochenschric,
HUMAN COMBUSTION.

1841, Nos. 8, 9, 10; also, Henke's Zeitschrift der S. A. 1842, ii. 228; 1843, ii. 39. See also Ann. d'Hyg. 1851, i. 99; ii. 383.)

We have, then, only to consider how far the views of those who allow that the body may acquire preternaturally combustible properties are consistently borne out by facts. It is generally admitted that the human body is highly difficult of combustion; and therefore, if in any case the degree to which it is consumed by fire is great in proportion to the small quantity of combustible matter destroyed about the person, it appears not unreasonable to refer this to its possessing greater combustible properties. This is precisely the species of evidence which is furnished by the alleged cases of spontaneous combustion: the body has been found almost entirely consumed, and the clothes and other articles of furniture surrounding it but little injured. Dr. Duncan came to this conclusion in cases in which two men were tried for the murder of their wives. It must be remembered, however, that a crafty assassin may employ naphtha or some inflammable spirit, of which no trace will be found, and the secret destruction of the body may therefore be due to this extraneous cause, and not to any increased combustibility of its parts. The contact of a volume of flame will speedily consume the body, owing to its high temperature and the large surface which it would at once envelope. Articles of female dress, from the quantity of air enclosed between the layers, are capable of producing much flame:—and in a body in which fat predominated, this would, after a time, add to and augment the effect of other combustibles with which it might be surrounded. Even allowing with Dr. Duncan that the human body may, in certain cases, acquire increased combustible properties, the medical jurist will perceive that this admission does not involve any difficulty in the judicial determination of a question of murder by burning, since it is contended that the combustion of the body cannot take place except by contact with ignited substances. But whether the ignition of the clothes of a deceased person took place accidentally, or by the criminal act of an accused party, is a totally different question,—it is one in which a medical jurist is no more concerned than a non-professional witness,—this is, in fact, a point which can be cleared up only by general or circumstantial evidence. If it be admitted that the body of one person will burn more rapidly and completely than that of another, this will be no ground of exculpation to a prisoner who is proved to have wilfully set fire to the clothes of that person. It may be urged in defence, that the prisoner might not have intended to destroy the deceased; and that although he ignited the clothes, he did it without any malicious intention; and that death would not have been caused by his act, but for the preternatural combustibility of the body of the deceased! The intention which a person may have had in setting fire to the clothes of another, when he
could not possibly know to what degree the burning would extend, is, of course, a question for a jury, to be decided from the circumstances. The relation of this subject of the alleged spontaneous combustion of the body to medical jurisprudence, appears therefore to have been much exaggerated. The only credible part of the doctrine can never present any sort of difficulty to a medical jurist.

_Homicidal mistaken for Spontaneous combustion_—It is singular that, so recently as the year 1850, some German physicians should have been found to advocate the hypothesis of spontaneous combustion in a case of murder. A trial took place at Darmstadt, in March and April 1850, in which a man named John Stauff was charged with the murder of his mistress, the Countess of Goerlitz. The Countess was found dead in her apartment; the dress on the upper part of the body was almost wholly consumed; the head exhibited the form of a nearly shapeless black mass, in which the mouth was imperfectly distinguishable, with the charred tongue protruding from it. The skin of the neck, as well as the skin and muscles of the face and upper part of the chest, were much blackened and charred. The joints of both arms were charred on their surfaces, and the blackened ends of the bones protruded. There were no marks of fire on the clothes anywhere beyond the margins of the burns on the body. A writing-desk near the body had been partially burnt, and the floor beneath and in front of the desk, over a space of a foot and a half, had been entirely consumed. The feet of a chair placed near the writing-desk were slightly charred. A folding board and the drawers were also much burnt. With this very clear evidence of the partial destruction of a human body by fire, the physician who was consulted could suggest no other explanation of the phenomena, than that the body of the Countess must have taken fire spontaneously, while she was engaged in writing at her desk! He could not even admit that her cap or dress might have become ignited by a candle, because, had this been the case, she would in his opinion, have had time to escape or call for assistance! The other reasons assigned for this hypothesis were, that deceased went to bed in good health,—that there was a greasy black or sooty substance found about the room, and the body exhaled an empyreumatic odour. It may be observed that when the room was first broken into, and the Countess was found dead, flames burst out simultaneously from the hangings, the writing-desk, and the floor beneath it, which required to be extinguished by the ordinary process,—namely, by water. The scientific opinion thus given amounted to this—the Countess's body had undergone slow combustion until it reached a full red heat; it then ignited the furniture around! The Countess was thus found dead on the 13th of June, 1847. On the 26th of November of that year, it was intimated to the Count that an inquest would
be held, and the valet Stauff, having made an attempt to poison his master, was then first suspected of having murdered the Countess, the death by burning having up to this time been treated as an accidental occurrence. The body, which had been buried, was exhumed on the 11th of August 1848, i.e. fourteen months after death: it was subjected to a special examination, and the Hessian Medical College, to whom the case was referred, came to the conclusion that the Countess had not died from spontaneous combustion. The case was subsequently referred to Prof. Liebig and Bischoff, of Giessen, and their report was issued in March 1850, at which date the man Stauff was put on his trial. They found no difficulty in coming to the conclusion that a murder had been perpetrated, and the body wilfully burnt after death for the purpose of concealing the crime. There was some doubt whether the deceased had died from strangulation or from violence to the head. Stauff was convicted upon circumstantial evidence. He subsequently confessed that the Countess had entered her room as he was in the act of committing a robbery. A struggle took place, he seized her by the throat, strangled her, and afterwards placed the body in a chair, piling around it combustible articles of furniture. He set fire to these with the view of destroying the proofs of his crime. It will be observed that the tongue was found protruded, as it is in violent strangulation, and in its charred state it retained the position given to it by the act of murder.

One of the difficulties in the case (as it was considered before the facts were known) was, that the body appeared to have been so much consumed compared with the amount of combustibles near it: another point which excited notice was, that the clothes were not consumed beyond the margins of the burns on the body, — a circumstance which has been hitherto regarded as a special character of spontaneous combustion. The dark greasy matter on the furniture and the empyreumatic smell are also conditions which by this case are proved to be results of the homicidal attempts to conceal a foul murder, and are not indications of spontaneous combustion. (See, for a further report of this case by Dr. Ogston, Medical Gazette, xlvi. 899 and 948.)

*Time required for the burning of a dead body.* — It may be a medico-legal question, whether, on discovering a body thus burnt, it could be determined from its appearance how long a period it would require to produce the amount of destruction observed. An answer to such a question may appear necessary, in order to connect a person with the perpetration of a crime; but the question does not admit of any precise answer: a conjecture may be formed from the facts proved in each particular case. The human body contains a large proportion of water: this gives to the soft structures a power of resisting combustion. At the same time there is a quantity of fat in the body, varying in different parts,
but amounting to an average of about five per cent. This tends to increase its combustibility; and this is still further increased if it be placed on any combustible articles,—such as a rug or a deal floor. The nature of the dress will also make a difference. Under a strong and active flame, which might subsequently burn out before the discovery of the body, there would be a degree of destruction in half an hour which a more slow and smothered combustion would not effect in several hours. In the case of the Countess of Goerlitz, it was proved that she retired to her room between 3 and 4 o'clock in the afternoon;—the Count returned at 7 o'clock, and knocked at the door of her anteroom, but, receiving no answer, he again went out. Had the burning of the body then commenced he would have perceived it by the smell, or by the appearance of smoke. He returned again at 9 o'clock, and during this second absence, covering an interval of two hours, a bright light had been seen at one of the windows, and a thick smoke issued from one of the chimneys. There is a little discrepancy as to the time, but, taking the maximum, the amount of destruction described in this case (see ante, p. 415) must have occupied less than two hours, and probably not more than one hour.

This question actually arose in the following case (Reg. v. Hatton, Aylesbury Lent Assizes, 1854). The deceased, a female, was found dead in her room, and her body much burnt. She was last known to be living at about a quarter past eight o'clock in the evening, and her body was found with fire still smouldering on the floor of the room at about a quarter past eleven o'clock. The only persons known to have been in the house were the prisoner and deceased. The prisoner pretended that he knew nothing of the circumstances attending her death, and endeavoured to make it appear that robbers might have broken into the house, and committed the murder, at some period of the three hours during which he alleged that he was asleep in bed. For the prosecution, it was suggested, in order to exclude this hypothesis, which, however, was sufficiently excluded by other facts, that the act of murder, with the attendant burning, must have occupied the whole of the time intervening between the period at which deceased was last seen living, and the period at which her body was found. The medical gentleman who examined the deceased found that "both knees were consumed by fire, and the thighs also burnt to a cinder; the private parts also,—leaving the shafts of the thigh-bones exposed and charred for several inches. Between the thighs and feet, the floor underneath was burnt away, and the leg-bones had fallen through the floor, leaving the feet unburnt on the floor." He expressed an opinion that it would take from two and a half to three hours in order to consume the body to this degree; thus covering the whole interval during which deceased and prisoner were in the house together.
It should be stated, that the clothes of the deceased were much burnt, and that beneath the body there was a hempen mat, so combustible, owing to the melted human fat with which it was impregnated, that when ignited it burnt like a link. The guilt of the prisoner did not depend on an answer to this question; that was made sufficiently clear from other circumstances proved in the case, which were quite inconsistent with his innocence. It is obvious that an opinion on such a subject must be in all cases conjectural, since the effects, ceteris paribus, depend as much on the intensity as on the duration of the heat. It was indeed just as probable, medically speaking, that, with a large body of flame, the amount of injury met with might have been produced in an hour as in three hours; and if the question were proposed to any number of medical men in entire ignorance of the bearing which their answers would have on the case, there would be probably no two answers alike. The confession of the prisoner, subsequently made, shows that the burning observed must have taken place in less than two hours, and probably within an hour and a half. The Goerlitz case and some others prove that a short period may suffice for a large amount of destruction, and that, judging by what remains, the combustible materials consumed appear to bear only a small proportion to the parts of the body burnt.

BURNS BY CORROSIVE LIQUIDS.

Among the cases in which medical evidence is sometimes required, are those of throwing sulphuric acid or other corrosive liquids on the person. This crime was at one time prevalent, and there was no adequate punishment for it. On one occasion, the prisoner escaped the charge of felony, because it could not be considered in law, that sulphuric acid was capable of producing a wound—the man having been indicted for wounding! This case clearly showed a strong necessity for some legal definition of a wound, as well as the uncertainty of medical opinions: for while one surgeon considered that the injury produced was a wound, another thought that it was not. The judges decided that it was not a wound within the meaning of the statute. (The King v. Murrow, Liverpool Assizes, 1835.) The Act 1 Vict. c. 85, s. v., while it punishes the offence, omits all reference to a definition of the word wound. The nature of the liquid thrown is merely defined in general terms to be "any corrosive fluid or other destructive matter"—a point which will require to be settled by medical evidence. In common language, and according to the statute, the injury thus produced is called a burn; but it is wholly different in its origin, as well as in its progress. I do not know that there has been a single instance in which such an injury has directly destroyed life; but great deformity and actual blindness have resulted. A medical man is sometimes required to distinguish these injuries from burns and
scalds:—this may be easily done in the first instance, by the appearance of the part injured, as well as by the description of the first symptoms. The stain is brown when sulphuric acid has been used, and yellow when nitric or muriatic acid has been employed. The eschar is soft, and not dry as in a burn from a heated solid. The skin touched by a concentrated acid is destroyed and sloughs away, leaving a suppurating and granulating surface. The period of recovery will depend on the extent of the injury. Although a person may not die from the direct effects of the acid, yet in certain irritable constitutions the inflammation which follows in deep-seated parts may prove fatal. In infants, or delicate nervous females, an extensive injury thus produced may readily destroy life. In the case of Miss Cashin, for whom an escharotic liniment was prescribed by a quack, there was no doubt that death was caused by the great local mischief produced by the application. The nature of the acid may be determined by applying wetted linen to the part when the injury is recent, and examining the liquid thus absorbed. In general, however, evidence is readily obtained by examining the spots or stains left on articles of clothing or furniture. Sulphuric acid is most commonly used; but in a case which occurred at Guy's Hospital, nitric acid had been thrown at the individual, and had led to the destruction of the sight of one eye. The caustic alkalies might also be used under these circumstances, as well as numerous other liquids, on which the only medical opinion required would be, whether the liquid employed should or should not be considered as corrosive or destructive matter. To constitute a felony, it is necessary that the person should have sustained, from the act of throwing, some grievous bodily harm.

The mineral acids are sometimes used in other ways for the destruction of life. In June 1833, a man poured a quantity of strong nitric acid into the ear of his wife while she was lying asleep. She awoke suddenly with a violent pain in the ear, which continued for three days, whereby she became weak and exhausted. Soon afterwards there was copious bleeding, and a portion of membrane escaped. She lost the use of her right arm, and became completely deaf. Suppuration took place from the ear, and blood escaped daily. She gradually sank, and died six weeks after the injury, the right half of the body being convulsed before death. On inspection, a portion of the external ear was wanting, and the ear-passage was much wider than natural. The brain, near the petrous portion of the temporal bone, was softened, and the bone itself carious. The injury had led to death indirectly by producing disease of the brain. (Medical Gazette, xvii. 89.)

In a case tried at Aberdeen, a woman poured oil of vitriol down the throat of her husband while he was lying asleep with
INFANTICIDE.

CHAPTER XXXVIII.

Nature of the crime.—By infanticide we are to understand, in medical jurisprudence, the murder of a new-born child. The English law, however, does not regard child-murder as a specific crime; it is treated like any other case of murder, and is tried by those rules of evidence which are admitted in cases of felonious homicide. In saying that infanticide is the term applied to the murder of a new-born child, it is not thereby implied that the wilful killing should take place within any particular period after birth. Provided the child be actually born and its body entirely in the world, it matters not whether it has been destroyed within a few minutes, or not until several days after its birth. In the greater number of cases of infanticide, however, we find that the murder is commonly perpetrated within a few hours after the birth of the child. Although the law of England treats a case of infanticide as one of ordinary murder, yet there is a particular difference in the medical evidence required to establish the murder of a new-born child. It is well known that in the course of nature, many children come into the world dead, and that others die from various causes soon after birth. In the latter, the signs of their having lived are frequently indistinct. Hence, to provide against the danger of erroneous accusations, the law humanely presumes that every new-born child has been born dead, until the contrary appears from medical or other evidence. The onus of proof is thereby thrown on the prosecution; and no evidence imputing murder can be received, unless it be made certain, by
medical or other facts, that the child survived its birth, and was actually living when the violence was offered to it. Hence there is a most difficult duty cast upon a medical witness on these occasions.

*Body of the child not discovered.* — In cases of child-murder, medical evidence is commonly founded upon an examination of the body of the child; but it must be borne in mind, that a woman may be found guilty of the crime, although the body of the child be not discovered: — it may have been destroyed by burning, or by being otherwise disposed of, and a medical witness may have only a few calcined bones to examine (Ann. d'Hyg. 1845, i. 129). In these cases of the non-production of the body, good legal evidence of the murder would, however, be demanded; and this evidence should be such as would satisfactorily establish a matter of fact before a jury. The production of the body of a child is therefore no more necessary to conviction than in any other case of murder. A woman has been tried for the murder of her child, the body of which was not discovered. It must not be supposed from this statement that the fact of the murder is to depend upon the fact of disappearance. There may be clear evidence of a child having been murdered, and its body so disposed of, at or immediately after the act of murder, as to render the production of the body impossible, as where a woman kills her child, and is seen to consume its body by fire, or to throw it at once into the sea, or into a deep lake or pond. In a case tried in Edinburgh in 1841, there were strong grounds for believing that the woman had disposed of the body of her child by throwing it to some half-starved pigs which had eaten it.

*Medical evidence at inquests.* — In most instances, however, the body of the child is found, — an inquest is held, and medical evidence is demanded. In giving evidence at a coroner's inquest on a case of infanticide, as much care should be taken by a practitioner as if he were delivering it before a judge at the assizes. Some witnesses are disposed to treat an inquest with indifference, and to be careless in their evidence, thinking probably that, should the case come to trial, they could prepare themselves and amend any statements which from subsequent reflection might appear to have been hastily made before a coroner. But it ought to be known that the depositions taken by this officer are at the trial placed in the hands of the judge as well as of the prisoner's counsel; and should a witness deviate in his evidence at the assizes from that which he gave at the inquest, or should he attempt to amend or explain any of the statements then made, so that they might, by the ingenuity of a barrister, be represented as having a new bearing on the prisoner's case, he would expose himself not merely to a severe cross-examination, but probably to the censure of the Court. If medical men were
Uterine age or maturity of the child.

One of the first questions which a witness has to consider in a case of alleged child-murder, is that which relates to the age or probable degree of maturity which the deceased child may have attained in utero. The reason for making this inquiry is, that the chances of natural death, in all new-born children, are great in proportion to their immaturity: and that supposing them to have survived birth, the signs of their having expired are commonly very obscure. It is found that the greater number of children which are the subjects of these investigations have reached the eighth or ninth month of gestation; yet charges of murder might be extended to the wilful destruction of children at the seventh month or under, provided the evidence of life after birth was clear and satisfactory.

Proof of viability not required.—The English law does not act on the principle that a child, in order to become the subject of a charge of murder, should be born viable, i.e. with a capacity to live. It is observed by Mr. Chitty, although no authority is quoted for the statement, that “the object of the law is to prevent injuries to infants having capacity to maintain a separate existence;” and he further suggests that such a capacity should be proved, in order to complete the offence of infanticide. (Med. Jur. i. 411.) This argument, carried to its full extent, would render it no offence to put to death all persons afflicted with any mortal disease. I have been unable to find, in the numerous reported trials for infanticide, any ground for this statement. The capacity of a child continuing to live has never been put as a medical question in a case of alleged child-murder; and it is pretty certain, that if a want of capacity to live were actually proved, this would not render the party destroying it irresponsible for the offence. Children may be born alive at the sixth or seventh month; but because they are much less likely to survive than those born at the eighth or ninth month, this is not a ground of exculpation for any person who may wilfully destroy them. The real question, as we shall presently see, does not refer to the period of gestation at which a child may be born, but to the fact of its being living and entirely born when the murderous violence is offered to it. The French law, although it requires in some cases proof of viability in relation to the rights of inheritance, demands only proof of life after birth in reference to a charge of infanticide. (Briand, Man. Complet de Méd. Légal. 201.)

Although the doctrine of viability is not recognised in English
jurisprudence, yet in a case which occurred in October 1836, a coroner refused to hold an inquest on the body of a child, because it had not reached an age (seven months) at which children are commonly born alive! In this case there was probably no harm done; but when we consider—1st, the great difficulty of determining the exact age of a child from the characters found on its body; and 2d, that many children born under the seventh month have not only been born alive, but have lived to adult age, the acting on a principle of this kind would be likely to give rise to dangerous abuses. It is impossible to admit that children are to be destroyed with impunity because they happen to be born under the seventh month, or that a child should be assumed to have been born dead, and any inquiry into the cause of death dispensed with, unless it can be medically established that it has passed the seventh month of gestation.

According to one medico-legal authority, if it can be proved that the child which is the subject of investigation has not attained this age (the seventh month), no charge of infanticide can or ought to be entertained. Are we to understand by this, that children proved to have been born living before the seventh month, may be wilfully destroyed, and the law take no cognisance of the matter? If this be not the meaning, the statement amounts to nothing, because whether the child have reached the seventh, eighth, or ninth month, life and live birth must still be proved, before the question of murder can be entertained. I have known an instance of a child born between the sixth and seventh months living a fortnight; and many similar cases are recorded. On the doctrine above laid down, the deliberate destruction of such children, although actually living, ought not to be considered or treated as murder! It is satisfactory to know that such a principle as this is not recognised by the law of England. In the case of Reg. v. West (Nottingham Lent Assizes, 1848), a midwife was tried on a charge of causing the death of a child under the seventh month of uterine life (in the perpetration of abortion), not by direct violence applied to its body, but merely by leading to its premature birth. This case proves, therefore, that a charge of infanticide may be fairly entertained with respect to children under the seventh month. The female in this instance was alleged to have been between the fifth and sixth month of pregnancy. The proof of this fact did not, however, prevent an indictment for murder, or a full investigation of the facts of the case. We also learn from it, contrary to the suggestion of Mr. Chitty (supra), that the viability of a child is not by the English law required to be proved on an indictment for child-murder. This child was certainly from mere immaturity incapable of maintaining a separate existence, and it was therefore not viable; but the judge who tried the case, in answer to an objection
taken by prisoner's counsel, said that if the child was proved to have died under the circumstances alleged for the prosecution, it would be murder.

Characters from the sixth to the ninth month.—The following are the characters whereby we may judge of the uterine age of a child from the sixth to the ninth month of gestation, a period which may be considered to comprise all cases of child-murder. Between the sixth and seventh:—The child measures, from the vertex to the sole of the foot, from ten to twelve inches, and weighs from one to three pounds. The head is large in proportion to the trunk,—the eyelids are adherent, and the pupils are closed by membranes (membranae pupillares). The skin is of a reddish colour, and the nails are slightly formed;—the hair loses the silvery lustre which it previously possessed, and becomes darker. Ossification proceeds rapidly in the chest-bone, and in the bones of the foot. The brain continues smooth on its surface:—there is no appearance of convolutions. In the male the testicles will be found in the abdominal cavity, lying upon the psoas muscles immediately below the kidneys. Between the seventh and the eighth months:—The child now measures between thirteen and fourteen inches in length, and weighs from three to four pounds. The skin is thick, of a more decidedly fibrous structure, and covered with a white unctuous matter, which now for the first time appears. Fat is deposited in the cellular tissue, whereby the body becomes round and plump:—the skin, previously to this, is of a reddish colour, and commonly more or less shrivelled. The nails, which are somewhat firm, do not quite reach to the extremities of the fingers. The hair becomes long, thick, and coloured. Ossification advances throughout the skeleton. Valvulae conniventes appear in the small intestines, and meconium is found occupying the cecum and colon. The testicles in the male are considered about this period to commence their descent,—or rather, the child's head being downwards, their ascent towards the scrotum. The time at which these organs change their situation is probably subject to variation. According to J. Hunter, the testicles are situated in the abdomen at the seventh, and in the scrotum at the ninth month. Burns believes that at the eighth month they will commonly be found in the inguinal canals. The observation of the position of these organs in a new-born male child is of considerable importance in relation to maturity, and it may have an influence on questions of legitimacy as well as of child-murder. Mr. Curling thus describes their change of position:—At different periods between the fifth and sixth months of fetal existence, or sometimes later, the testicle begins to move from its situation near the kidney towards the abdominal ring, which it usually reaches about the seventh month. During the eighth month it generally traverses the inguinal canal, and by the end of the ninth, arrives at the bottom,
of the scrotum, in which situation it is commonly found at birth. (Diseases of the Testis, 2nd ed. p. 17.) Its absence from the scrotum does not necessarily indicate that the child is immature, because the organ sometimes does not reach the scrotum until after birth.

Between the eighth and ninth months the child is from fifteen to sixteen inches in length, and weighs from four to five pounds. The eyelids are no longer adherent, and the membrane pupillares will have disappeared. The quantity of fat deposited beneath the skin is increased, and the hair and nails are well developed. The surface of the brain is grooved or fissured, but presents no regular convolutions; and the cineritious matter is not yet apparent. The meconium occupies almost entirely the large intestines; and the gall-bladder contains some traces of a liquid resembling bile. The testicles in the male may be found occupying some part of the inguinal canal, or they may be in the scrotum. The left testicle is sometimes in the scrotum, while the right is situated about the external ring.

Signs of maturity.—At the ninth month the average length of the body is about eighteen inches, and its weight about six pounds, or between that and seven pounds: the male child is generally rather longer, and weighs rather more than the female. Extraordinary deviations in length and weight are occasionally met with. Mr. Owens, of Ludlow, met with a case in which the child at delivery measured twenty-four inches, and weighed seventeen pounds twelve ounces. (Lancet, December 1838.) In a case which I was required to examine in June 1842, the child, a male, measured twenty-two inches, and weighed twelve pounds and a half. (For some practical remarks on the subject, by Dr. Ellsässer, see Henke's Zeitschrift, 1841, ii. 235.) At the full period, the head of the child is large, and forms nearly one fourth of the whole length of the body. The cellular tissue is filled with fat, so as to give considerable plumpness to the whole form, while the limbs are firm, hard, and rounded. The skin is pale. The hair is thick, long, and somewhat abundant. The nails are fully developed, and reach to the ends of the fingers;—an appearance, however, which may be sometimes simulated in a premature child, by the shrinking of the skin after death. The testicles in the male are generally within the scrotum. Ossification will be found to have advanced considerably throughout the skeleton. (See, in relation to the progress of ossification, a paper by M. Ollivier, Ann. d'Hyg. 1842, 343.) The surface of the brain presents convolutions, and the cineritious matter begins to show itself. The internal organs, principally those of the chest undergo very marked changes, if the act of respiration have been performed by the child before, during, or after its birth.

The relative position of the point at which the umbilical cord is attached to the abdomen, has been considered by some
medical jurists to furnish evidence of the degree of maturity. Chaussier thought that in a mature child, at the ninth month, the point of attachment of the cord exactly corresponded to the centre of the length of its body. Later observations, however, have shown that this is not quite correct. Out of five hundred children examined by M. Moreau, at the Maternité, in Paris, the umbilical aperture corresponded to the centre of the body in four cases only. In the majority of these cases, the point of insertion was eight or nine lines below the centre. Among many cases of mature children which I have had an opportunity of examining, the umbilical aperture has generally been situated from a quarter to half an inch below the centre of the body. (Guy's Hosp. Rep. April 1842.) M. Moreau found, on the other hand, that in some children, born about the sixth or eighth month, the cord was attached at the middle point of the length. (Lanc. Franç. 1837.) On the whole, it will be perceived that no value can be attached to the situation of the umbilical opening, as a sign of maturity or immaturity.

The characters which have been here described as belonging to a child at the different stages of gestation, must be regarded as representing an average statement. They are, it is well known, open to numerous exceptions; for some children at the ninth month are but little more developed than others at the seventh; although the converse of this proposition is not true—i.e., we do not find that children of the seventh month have undergone such premature development as to be mistaken for children at the ninth month. Twins are generally less developed than single children;—the average weight of a twin child is not more than five pounds, and very often below this. The safest rule to follow in endeavouring to determine the uterine age of a child is to rely upon a majority of the characters which it presents. That child only can be regarded as mature, which presents the greater number of the characters already described, and which are met with in children at or about the ninth month of gestation.

If the age of the child has been determined:—whether it be under or over the seventh month, the same rules for a further investigation will be demanded. Should the child be under the seventh month, the medical presumption will be, that it was born dead; but if it has arrived at its full period, then the presumption is that it was born alive.

Conclusions.—The following may be taken as a summary of the principal facts upon which our opinion respecting the uterine age of a child may be based:—

1. At six months.—Length, from nine to ten inches; weight, one to two pounds; eyelids agglutinated; pupils closed by membrane pupillares; testicles not apparent in the male.

2. At seven months.—Length, from thirteen to fourteen inches; weight, three to four pounds; eyelids not adherent; membrana.
pupillares disappearing; nails imperfectly developed; testicles not apparent in the male.

3. At **eight months**. — Length, from fourteen to sixteen inches; weight, from four to five pounds; membranae pupillares absent; nails perfectly developed, and reaching to the ends of the fingers; testicles in the inguinal canal.

4. At **nine months**. — Length, from sixteen to twenty-one inches; weight, from five to nine pounds; membranae pupillares absent; head well covered with fine hair; testicles in the scrotum; skin pale; features perfect—these and the body are **well developed**, even when the length and weight of the child are much less than those above assigned.

5. The point of attachment of the umbilical cord, with respect to the length of the body, affords no certain evidence of the degree of maturity.

**Inspection of the body.** — The questions which a medical jurist has to solve, in examining the body of a new-born child, are—

1. To determine its age, or the stage of uterine life which it has reached;—2. Whether it has lived to breathe;—3. Whether it has been born alive;—4. The period of time which has elapsed since its death;—5. The cause of death, whether violent or natural.

Hence, before commencing the inspection—

1. The length (measured from the vertex to the sole of the foot) and weight of the body should be taken;—2. The presence or absence of external fetal peculiarities noticed;—3. Any peculiar marks or indications of deformity whereby identity may be sometimes established;—4. All marks of violence in the shape of wounds, bruises, or lacerations, and the kind of instrument or weapon by which they were probably produced; 5. Whether the umbilical cord has been cut and tied, or lacerated; the appearance of the divided vessels, and the length of that portion which is still attached to the body of the child;—6. The presence or absence of vernix caseosa about the groins, arm-pits, or neck—the presence of this substance proves that the child has not been washed or attended to;—7. It will be necessary to state whether there are about the body any marks of putrefaction, indicated by a separation of the cuticle, change of colour in the skin, or offensive odour. It is obvious, that unless these circumstances be noticed before the inspection is commenced, they may be entirely lost as evidence. Notes should be made on the spot, and the original retained, even if copies be subsequently made.
CHAPTER XXXIX.

ON THE PROOFS OF A CHILD HAVING LIVED AT ITS BIRTH—EVIDENCE OF LIFE BEFORE RESPIRATION—SIGNS OF PUTREFAC-
TION IN UTERO—EVIDENCE FROM MARKS OF VIOLENCE—SUMMARY—EVIDENCE OF LIFE AFTER RESPIRATION—INSPE-
CTION OF THE BODY—COLOUR, VOLUME, CONSISTENCY, AND ABSOLUTE WEIGHT OF THE LUNGS—STATIC TEST—WEIGHT 
INCREASED BY RESPIRATION—TEST OF PLOUCQUET—BLOOD IN 
THE PULMONARY VESSELS—RELATIVE PROPORTION OF FAT IN 
THE LUNGS—SPECIFIC GRAVITY OF THE LUNGS—GENERAL 
CONCLUSIONS.

On the proofs of a child having lived at its birth.—The question 
whether a child was or was not born alive, is of the greatest 
importance in a case of alleged child-murder; and it is unfor-
tunately one which, in respect to the proofs upon which medical 
evidence is commonly founded, has given rise to considerable 
controversy. When it is stated that in most cases of alleged 
infanticide that end in acquittals in spite of the strongest moral 
 presumptions of guilt, the proof fails on this point only, it must 
be obvious that this question specially claims the attention of a 
medical jurist. The medical evidence of a child having been 
alive, when violence was offered to it at its birth or afterwards, 
may be divided into two parts: 1, that which is obtainable before 
the act of respiration is performed; and 2, that which is obtain-
able afterwards. At present it will be proper to confine our 
attention to the question, whether the child was alive when it 
was maltreated,—the fact of its having been born alive will be a 
matter for future consideration. These two questions have been 
frequently but improperly associated, thus rendering the subject 
confused; but it must be so obvious as scarcely to require stating, 
that violence of a murderous kind may be offered to a living 
child before it is entirely born; and that owing to this violence 
it may come into the world dead.

EVIDENCE OF LIFE BEFORE RESPIRATION.

It was formerly supposed, that if the lungs contained no air, 
the child could not have respired, and that it must have been 
born dead. But neither of these views is correct;—children have 
been known to respire faintly, and continue in existence many 
hours without visibly distending the cells of the lungs with air,— 
the absence of air from the lungs, therefore, furnishes no proof 
either that respiration has not been performed, or that the child 
has not lived. (G. H. Rep. April 1842.) That our law-authori-
ties will admit evidence of life in a child before the establish-
ment of respiration, is clear from the decision in the case of Rex v.
Brain, in which the judge said, that a child might be born alive, and not breathe for some time after its birth (Archbold, Crim. Pleas. 367), as also from the charge of Coltman J. in the case of Rex v. Sellis (Norf. Spr. Circ. 1837). In this instance it was alleged that the prisoner had murdered her child by cutting off its head. The judge directed the jury, that if the child were alive at the time of the act, it was not necessary, in order to constitute murder, that it should have breathed. In fact, it would appear that respiration is regarded as only one proof of life; and the law will, therefore, receive any other kind of evidence which may satisfactorily show that the child has lived, and make up for the proof commonly derived from the state of the lungs. It will be first incumbent on a medical practitioner to prove that the child under examination has recently died, or in other words, that there are good grounds for believing it to have been recently living. Hence, if the body be highly putrefied, either from the child having died in the uterus some time before birth, or from its having been born and its body not discovered until putrefaction had far advanced both internally and externally, the case is utterly hopeless. The medical witness will in general be compelled to abandon the investigation, because the body can furnish no evidence whatever of life after birth. The examination of the thoracic organs would throw no light on the case, for here we are assuming that the lungs are in their fetal condition.

Signs of Putrefaction in utero.—The phenomena of putrefaction in air require no notice in this place; but the changes which ensue when a child dies and is retained within the uterus, may be briefly adverted to, because they may sometimes form a subject for judicial inquiry. According to Devergie, when a child dies in utero, putrefaction takes place as rapidly as in the open air (Méd. Lég. i. 526); but this is doubtful. In an advanced stage of uterine putrefaction, the body of the child is so succed, that when placed on a table it becomes almost flattened by the mere gravitation of its parts. The skin is of a reddish-brown colour, not green as in a putrefied body exposed to air. The cuticle covering the feet and hands is white, and sometimes raised in blisters,—the cellular membrane is filled with a reddish-coloured serum, the bones are movable, and readily detached from the soft parts. In the opinion of Devergie, the principal difference between uterine and atmospheric putrefaction in the body of a new-born child, is seen in the colour assumed by the skin:—but it must be remembered, that should the child remain exposed to the air after its expulsion, the skin may acquire the colour observed in cases of atmospheric putrefaction. The changes which have just been described are such as we may expect to find when the child has been retained in utero eight or ten days after its death. When it has remained for some weeks in the uterine cavity, the body has occasionally been found saponified, or even encrusted with phos-
phate of lime. If in any case we are able to state distinctly that
the body of a child has undergone uterine, and not atmospheric,
putrefaction, it is clear that it could not have come into the world
alive. Under ordinary putrefaction in air, the child may have
been really brought into the world living, and the process may
have destroyed every proof of that fact.

Let us suppose that the child died in utero from forty-eight to
twenty-four hours before it was born; if it be soon afterwards
examined, there will be no marks of putrefaction about it, and
the appearances will closely resemble those met with in the body
of a child which has been born alive, and died without res-
piring; or of one which may not have been born alive, but have
died in the act of birth. It will be impossible to say, in such a
case, whether the child came into the world living or dead.

*Evidence from marks of violence.*—It has been proposed to seek
for evidence of life, under these circumstances, by observing the
characters presented by marks of violence on the body. In
general, when children are murdered, the amount of violence in-
forced is considerably greater than that which is required to
destroy them, whereby satisfactory proofs of the crime are occa-
sonally obtained. On the other hand, the body of a still-born
child, dead from natural causes, is often covered with lividities
and ecchymoses;—the fetal blood does not coagulate with the
same firmness as in the adult: hence the evidence derivable from
the extent, situation, and characters of marks of violence, is
generally of too vague and uncertain a kind to allow of the ex-
pression of a medical opinion that the child was certainly living
when the violence was offered to it. The characters which have
been already described as peculiar to wounds and contusions
inflicted during life, may be met with in a child, whether it has
breathed, or died without respiring. So, again, these characters
are open to the exceptions there pointed out; for they will be
equally present, supposing the wounds to have been inflicted im-
mediately after the cessation of respiration or circulation in the
child, or after the cessation of circulation only,—if the act of
respiration have not been performed. Marks of violence on the
body of a child which had died in utero twenty-four or forty-
eight hours before it was born, would not present the characters
of injuries inflicted on the living. There would be no ecchymosis
and no effused coagula of blood. These marks, when they exist,
although they may establish that a child was either living or
but recently dead at the time they were inflicted, can never show
that it was born alive. Injuries met with on the bodies of
children alleged to have been born dead ought, however, to be of
such a nature as to be readily explicable on the supposition of
their having arisen from accident. If, from their nature, extent,
or situation, they are such as to evince a wilful design to injure,
it is a fair ground for a jury,—not for a medical witness, to in-
quire why these extensive wounds, or other marks of violence, were inflicted on a child, if, as it is alleged, it was really born dead. It must be confessed that in such a case there would be a strong moral presumption of murder, although medical proof of life, or actually live birth, might totally fail.

Summary, — As a summary of these remarks, it may be observed, that although physiologically a child may live for a certain period after its birth without respiring, — and legally its destruction during this period would amount to murder, yet there are at present no satisfactory medical data to enable a witness to express a positive opinion on this point. If other evidence were adduced of a child having lived and been destroyed under these circumstances, — as where, for example, a woman causes herself to be delivered in a water-bath, or an accomplice covers the mouth of an infant in the act of birth, or immediately after it is born,—a medical witness would be justified in asserting that the absence of the signs of respiration in the lungs was no proof that the child had been born dead. Indeed, it is apparent that the process could not be established, owing to the criminal means actually employed to prevent it. Whether a jury would convict upon such evidence is doubtful; but this is of no importance to the witness: — his statements ought always to be made according to correct and well-ascertained principles, and not for the purpose of procuring either the conviction or acquittal of parties accused of offences against the laws. In general, those cases in which questions relative to life before respiration might arise are stopped in the Coroner’s Court,—the usual practice being, when the signs of respiration are absent or imperfect, to pronounce that the child was born dead. If the lungs sank in water, the presence of marks of violence on the body would be considered as furnishing no evidence: — for the sinking of the lungs would be taken as positive evidence of stillbirth, an inference upon which some remarks will be made in speaking of the hydrostatic test. The following case was the subject of a criminal charge at Havre, in 1828: — A woman was delivered of twins. So soon as the first child was born, but not before it had breathed, she killed it by fracturing its skull with a wooden shoe. In a few minutes afterwards the second child was born, but scarcely had its head presented, when she seized it and fractured its skull in the same manner. This double crime was soon discovered. On an examination of the bodies of both children, the same degree of violence was found, presenting in each case precisely similar characters. There could be no doubt, from the appearance of the injuries, that they must have been inflicted on both children at a time when the circulation was going on. In one child, however, it was proved that respiration had taken place; in the other that it had not. In the latter case many practitioners would at once have affirmed that the child had not lived, because there was no proof that it had
respired; and they would have proceeded to draw the inference that this could not have been a case of infanticide. Dr. Bellot, however, stated that, although the child had not breathed, he had no doubt, it had been born alive, and that it would have lived to respire, but for the violence inflicted. This opinion was chiefly founded upon the similarity in the characters presented by the marks of violence in the two cases. (Annales d’Hygiène, 1832, ii. 199.) See further remarks upon this subject, by M. Ollivier, Ann. d’Hyg. 1843, i. 149; also by M. Devergie, op. cit. 1837, i. 400.

The great question involved in this, and in all similar cases, is the following:—Does the law regard the wilful prevention of respiration as murder? There cannot be the slightest medical doubt that living children are occasionally thus destroyed in the act of birth: they die, not from the actual infliction of violence, but because, either through accident or design, the performance of that act which is necessary to maintain existence when the child is born, is prevented. Such a case has not yet been decided, although from the dicta of our judges, it would probably involve a charge of murder. In a case published by Dr. Wharrrie, a pregnant woman, thinking she was about to have a motion, sat on an earthen pitcher, two feet in depth, which happened to be full of water. She was there delivered of a child, which fell into the water, and was thus prevented from breathing. The child was full-grown, and its body was free from putrescence. It weighed six pounds, and measured twenty inches. There were no external marks of violence, and the cord had been tied. The lungs weighed two and a half ounces; they were of a liver colour, contained no air, and sank in water. The medical opinion was, that from the size and general appearance of the child, and the state of the parts discovered on dissection, it was mature,—that it had never breathed, and life might have been either wilfully or accidentally destroyed. The examiners wisely declined giving the usual opinion from the sinking of the lungs; i.e., that the child had been born dead. The woman was not prosecuted, probably on the assumption that the death of the child might have been accidental. As Dr. Wharrrie truly observes, there was no medical proof that the child was born alive; although there was a strong moral presumption that life was extinguished after birth. (Ed. Monthly Jour., Oct. 1845, p. 796.)

Dr. Bayard mentions a case, in which a female, under somewhat similar circumstances, was convicted of the murder of her infant, and sentenced to the galleys for five years. In this case, there was no evidence of respiration, but the woman admitted that she fractured the skull of the child, with the intention of destroying it, thinking that she perceived a motion in its legs after it was born. (Ann. d’Hyg. 1847, i. 435.) One physician
436 INFanticide. COLOUR AND VOLUME OF THE LUNGS.

if by distension, above the general surface of the organs. The light red tint changes, after a short exposure to air, to a bright scarlet. This change in the colour of the lungs is not a necessary, nor is it an invariable consequence of a child having lived after its birth. I have known a child to live twenty-four hours respiring feebly, and on examining the body, the colour of the lungs was identical with that of the organs in the fetal state. The change of colour is then a usual, but by no means a necessary consequence of the enjoyment of life:—so that the retention of the fetal colour does not furnish positive evidence of still birth. Again, the circumstance of the lungs having a light red colour is not an infallible criterion of the child having lived and breathed; for the artificial introduction of air by a tracheal tube, or otherwise, in the attempt to resuscitate a still-born child, is attended with the same physical change. In the course of numerous experiments, purposely made, I have found no appreciable difference. Bernt says, that artificial inflation will not produce a scarlet red colour in the organs, and therefore that this is a criterion of respiration. (Ed. Med. and Surg. Jour. xxvi. p. 367.) I have not only observed this colour to be absent after respiration, but have actually produced it by artificial inflation in the lungs of a dead child.

2. Volume of the lungs.—The difference in the relative situation of the lungs before and after respiration, has been already described. This difference depends entirely upon the increased volume or dilatation of the organs, arising from the introduction of air. Before respiration, the lungs are in general scarcely visible, unless forcibly drawn forwards in the chest. When respiration has been perfectly accomplished, the volume is so much increased, that the bag of the heart (pericardium) is almost concealed by them. Respiration must, however, have been very perfectly performed in order that this condition should exist to the full extent described; but I have known the lungs to acquire a considerable volume in a healthy and vigorous child from only two or three resiprations. The child was destroyed by craniotomy, and died before it was entirely delivered. In other instances, a child may live for one or two days, and the volume of the organs be but little altered. Schmitt has remarked, that the lungs have sometimes a considerable volume before respiration. I have met with this in more than one instance; but this condition will probably be found in general to depend on disease. As the altered volume of the healthy lungs depends on the introduction of air, the effect is the same, whether the air be derived from respiration, from artificial inflation, or generated by postrefraction. Other circumstances must therefore be considered, before we draw an inference from this physical change.

3. Consistency of the lungs.—The lungs, before respiration, feel like the liver, or any other of the soft organs of the body. They
are firm under the finger, but their substance may be lacerated by violent compression. After respiration has been fully performed, there is a distinct sensation of what is termed crepitus on compressing them, i.e. air is felt within them. This condition of the organs must, of course, depend on the degree to which respiration has been carried. The lungs of children that have lived for a considerable time after birth, will sometimes give no feeling of crepitation under the finger. Generally speaking, lungs of this kind present the other fatal characters;—thus they are small and of a livid colour. There are, however, cases in which the lungs may have the light red colour of respiration, and be actually much dilated in appearance, yet no feeling of crepitus will be perceptible on pressure. This character, therefore, is by no means a necessary accompaniment of the other two. Crepitation furnishes presumptive evidence of respiration; but it may be equally met with in lungs that are putrefied, or which have received air by artificial inflation. The characters here described are seldom found in the lungs of children that have been born prematurely, although these children may have lived some time after birth. They depend on respiration; and, in the exceptional cases referred to, this process is only very slowly established.

4. Absolute weight of the lungs. The static test.—It is generally admitted by medical jurists, that the weight of the lungs before respiration is less than that which they have after the establishment of the process. From this an inference has been drawn that the absolute weight of the lungs in an unknown case, compared with certain averages, will aid the inquirer in ascertaining whether respiration has or has not been performed. In order to determine the weight of the lungs, these organs should be carefully separated by dissection from the heart and thymus gland, and removed with the trachea and bronchi attached. Previously to their removal, ligatures should be placed on the pulmonary vessels, so that no blood may escape from the lungs. They should now be weighed, and the weight accurately noted in grains. In taking this weight it does not appear necessary to make any distinction founded on the sex of the child, or on the difference of weight in the two lungs; the only exception would be, perhaps, in relation to twin children imperfectly developed. The average weight before respiration, derived from nine cases, was found to be 649 grains. According to Dr. Traill, the weight varies from 430 to 600 grains. It is of importance, in taking the weight of these organs, to be certain that the child is at or near maturity, and that it is of or about the average size and weight; owing to a neglect of this rule, it is highly probable that comparisons have been made of the absolute weight of the lungs in different children, which a full statement of the facts would not have justified. If it be immature, or unusually large, the lungs will weigh either less or more than the average. The average weight of the lungs.

It is of importance, in taking the weight of these organs, to be certain that the child is at or near maturity, and that it is of or about the average size and weight: owing to a neglect of this rule, it is highly probable that comparisons have been made of the absolute weight of the lungs in different children, which a full statement of the facts would not have justified. If it be immature, or unusually large, the lungs will weigh either less or more than the average. The average weight of the lungs...
after respiration, derived from three cases, was 927 grains; but in making an estimate of this kind much will depend upon the degree to which respiration has been carried. In three cases, in which the children lived half an hour, six hours, and twenty-four hours respectively, the process had been so imperfectly performed, that the lungs varied but little in weight from the average before respiration. (G. H. Rep. No. V.) The truth is, we cannot compare the lungs of children, as to weight, according to the time which they may have survived birth, but rather according to the degree to which the lungs have been penetrated by air. In one instance of alleged infanticide, where the child was probably killed soon after birth, the lungs weighed 1000 grains. In another instance, where the child had certainly lived eight or nine days, the lungs weighed only 861 grains. In the first case, respiration had been perfectly performed; in the second, imperfectly. Hence, to say that the lungs weigh so much after respiration, amounts to nothing, unless we can estimate, by a sight of the organs, its degree: and any calculation founded upon such dissimilar cases must unavoidably lead to error. This increase of weight after birth is commonly ascribed to the altered course of the blood under the establishment of the respiratory process, as well as to the fact, that more blood circulates through the lungs after, than before respiration. Practically, this view is confirmed by the contraction of the ductus arteriosus, and the simultaneous enlargement of the two pulmonary arteries; changes which have been occasionally observed when the child had survived its birth for only a very short period. As these normal changes in the duct depend on the establishment of respiration, so we cannot expect to find them when the process has been imperfectly performed, although the child may have lived several days.

Weight of the lungs increased by respiration.—It appears to me that the general opinion on this subject is correct, namely, that the healthy lungs of mature new-born children become heavier after respiration, and according to its degree; and where a deviation from this rule is observed, it may probably be explained by the circumstance that the lungs of an immature have been compared with those of a mature child, the lungs of an undeveloped twin with those of one not a twin, or the lungs of one which had breathed imperfectly with those of another in which respiration had become well established. In this respect the extensive tables drawn up by Lecieieux are liable to lead to erroneous inferences relative to the effect of respiration on the absolute weight of the lungs. The weights of the organs are noted, but the degree to which respiration had been performed is so loosely stated, as to allow of no fair inference of the effect of this process upon the weight. The time which the children survived is stated; but this, as it is very well known, furnishes no criterion of the degree to which respiration has been carried. Again, we are not informed whether due care was taken to ascertain if the lungs were
healthy or diseased. (Considérations sur l’Infanticide. Paris, 1819.) The following table of the weight of the lungs, in four cases, will show how much the organs are liable to vary in weight after birth, according to the degree of respiration.

Relying upon a table of this kind only, without comparing the other characters of the lungs with the weight, it might be inferred that the organs would weigh less in a child which had survived its birth twenty-four hours, than in another which had been born dead, and that there would be very little difference in the weight, whether the child lived six hours or nine days; but when it is stated, that in Case 3 the lungs had every fetal character possessed by those in Case 1, and that in Case 4 respiration had been obviously very imperfectly performed,—the difficulty is removed. Such cases should rather be compared with the lungs in the fetal than in the respired state. They merely show what is very well known to, and admitted by, all medical jurists, that there are some instances in which the fact of respiration cannot be determined by the application of the static, or any other test, to the lungs. But this is certainly no valid reason why evidence from this source is to be rejected in all other cases. It may be fairly granted that the weight of the lungs of some children that have outlived delivery, may not come up to the weight assigned to those of children that have breathed; because, as we have seen, children may survive birth many hours without the process of respiration being properly established. On the other hand, as in Chaussier’s observations, the lungs of the still-born may be sometimes as heavy as those of children that have expired; but since the lungs of the still-born would contain no traces of air, the weight above the average in these cases could not be assigned to respiration. Among such subjects, whatever might be the weight of the lungs, if the facts were unknown, it would be impossible to say whether the children were born living or dead. (See Ed. M. and S.J. xxvi. p. 375.) Increased weight, therefore, is only one among several circumstances to which a medical jurist should attend.

We must not fall into the error of supposing that the lungs increase in weight according to the length of time which a child survives its birth; it is within the limits of a few days, according to the degree of perfection with which a child breathes: hence we may meet with cases of children born alive, surviving some hours or days, and yet after death the lungs will retain their fetal weight. This is the case in immature children, in most twin children, and in those which are mature but weakly. Among many instances that have come to my knowledge, no difficulty of
this sort, however, has occurred. The signs of respiration have been sufficiently well developed to justify a medical opinion, although the child had probably not survived its birth above a few hours, or even minutes. (G. H. Rep. April, 1842.) The cases of imperfect respiration above alluded to rarely go beyond a coroner’s inquest, for want of clear evidence of life. There may be a difference of opinion as to the relative number of instances of perfect and imperfect respiration in new-born children; but a case is never likely to proceed to trial, unless the signs of this process are well marked; and thus many charged with murder must escape, through the want of sufficient medical evidence to establish the fact of respiration and life.

It is scarcely necessary to observe, that the air which the lungs receive by respiration cannot add to their absolute weight. This is because they are in the condition of a bladder, which weighs the same whether it be filled with air or empty. The increase of weight is solely due to the additional quantity of blood, which, owing to the altered course of the circulation, permeates their structure. Hence it follows that when the lungs are distended with air, either from artificial inflation or from putrefaction, the foetal weight will remain unaltered; and by this means, it is contended, we may distinguish lungs that have respired from those which have been artificially inflated. Orfila states, that the foetal lungs weigh more before they are artificially inflated, than afterwards,—a circumstance which may depend upon the fact that the impulse employed in inflation may have forced out a portion of blood or other liquid. In carefully performing this experiment, I have found that there was not even the least fractional difference; but that the inflated lungs weighed precisely the same as in the uninflated state. From what has already been said, it follows that great weight of the lungs can obviously furnish no proof of respiration, unless this be accompanied by the other physical changes indicative of that process,—as, for example, great increase in volume from the presence of air and crepitation. If the lungs be very heavy, and at the same time contain little or no air, it is certain that the increase of weight must depend upon disease or other causes,—not upon respiration. In one case which I had to examine, the lungs were large, and weighed upwards of 1200 grains. They contained no air; when divided into thirty pieces,—not one portion floated, nor could any air be seen on the closest examination. It was therefore clearly impossible to ascribe a weight so much above the average to the effects of respiration. It must not be forgotten that all the physical characters presented by lungs that have respired, are liable to certain fallacies; but, as in the evidence derived from tests used in poisoning, these may be removed, or the force of the objection diminished, by not basing an opinion on one or two conditions only. We must take the whole combined; for it would be as wrong to regard great
weight in the lungs *taken alone* as an absolute proof of respiration, as it would be to draw the same inference from a mere change in the colour, volume, or consistency of the organ. This is the view also taken by Professor Orfila. (Méd. Lég. 1848, ii. 229.)

5. Test of Plouguet.—This so-called test for determining whether or not the act of respiration has taken place, was proposed many years since by M. Plouguet. It is founded on a comparison of the absolute weight of the lungs with the weight of the body of a child. Admitting that the lungs increased in weight from the establishment of the respiratory process, it was supposed that a like difference would take place in the relative weight of these organs to the body; and that the ratios thus procured, compared with certain averages, would enable a medical jurist to determine, in an unknown case, whether or not a child had respired.

Plouguet conceived that the average ratio of the weight of the lungs to the body, in children which had not breathed, was 1 : 70; and in those which had breathed, 2 : 70 or 1 : 35. Subsequent researches, however, made by Chaussier and others, have shown that these numbers cannot be considered to represent the true averages. The most serious objection to the employment of this test, in cases of infanticide, is, that the lungs and the body are liable to vary in their relative weights, in children of the same age; and *a fortiori*, this variation must exist to a greater extent among children which have reached different ages. There may be various degrees of development in the body of a child, without any necessity existing for a corresponding development taking place in the lungs. It is unnecessary to enter into speculations relative to the causes: experience has shown that such variations really exist; and all that a medical jurist has to consider, is whether the difference can be reduced within limits which may make the test available in practice. M. Devergie states from his experiments, that Plouguet’s test affords no satisfactory results, when applied to the bodies of children which have not reached the eighth month of gestation. According to him, the ratio is, for the Eighth month—Before respiration, 1 : 63; after respiration, 1 : 37; Ninth month—Before respiration, 1 : 60; after respiration, 1 : 45. The ratio, he observes, becomes higher after respiration, in proportion to the perfection with which the process has been carried on. (Médecine Légale, i. 556. See also Ann. d’Hyg. 1835, i. 485; Med. Gaz. Nov. 1842, p. 208.) The facts which have been collected by different observers appear to me to show that Plouguet’s test is not fitted to determine, in an unknown case, whether a child has breathed or not.

6. Blood in the pulmonary vessels.—It has been asserted that if blood be found in the pulmonary vessels of a new-born child, we are justified in assuming that respiration has taken place.
On the other hand, the absence of blood from these vessels has been considered to prove that a child has not respirèd. This assertion must have originated in a want of correct observation. The pulmonary vessels contain blood, both in the child which has, and in that which has not, respirèd. It is possible that the vessels may contain more after respiratio than before; but in most cases of infanticide it would be difficult to found any distinction on a point of this nature. In examining the bodies of children which have died without respiring, and those of others which have lived and respirèd for some time after birth, no perceptible difference was found in the quantity of blood existing in the vessels in the two cases. The fact is, the excess of blood after the establishment of respiratio is distributed throughout the minute capillary system of the lungs: it does not remain in the large trunks. The state of the pulmonary vessels, therefore, furnishes no evidence of respiratio or the contrary. The same observation will apply to the presence of blood in the substance of the lungs. It is said that on cutting through lungs that have breathed, the incisions are followed by a copious flow of blood; this, it is alleged, does not happen with lungs that have not breathed. In performing this experiment on several occasions, I have not been able to perceive any well-marked difference. The blood in the new-born child may be found coagulated or not, and there is no difference in this condition, whether it be born living or dead.

7. Relative proportion of fat in the lungs.—In July 1847, a memoir was presented to the Academy of Sciences by M. Guillot, in which the author proposed to determine the question of respiratio by the relative proportion of fat contained in the lungs before and after birth. According to M. Guillot, the quantity of fat contained in the pulmonary tissue is always greater before than after respiratio, and it begins to diminish from the moment that the act of breathing commences. Before respiratio, the dried lungs yield from ten to eighteen per cent. of fat; after respiratio, not more than six per cent. The process, followed by M. Guillot, is to dry the organs at a high temperature, so as to expel all the water,—reduce them to powder, and digest this powder in ether. (Comptes Rendus, Juillet 12, 1847, 777.) It need hardly be observed that this process could not be made available in practice. Admitting the facts as stated, the assigned difference between six and ten per cent. may disappear by further observations. A want of chemical accuracy might lead to serious mistakes. The process, however, is open to this objection:—if respiratio has been fully performed, this will be sufficiently evident from the state of the lungs; and if imperfectly performed, as the change is alleged to depend on the respiratory act, the result of an analysis would not remove the difficulty.

8. The specific gravity of the lungs.—The specific gravity of the lungs is greater before than after respiratio; for although
the organs become absolutely heavier by the establishment of the process, this is owing not to the air, but to the additional quantity of blood received into them. The air thus received, so increases the volume of the lungs, as to more than counteract the additional weight derived from the blood, and thus apparently to diminish their specific gravity. Under these circumstances they readily float on water. From several experiments, I have found that the specific gravity of the lungs before respiration, i.e., in the foetal condition, varies from 1·04 to 1·05. They are about one-twentieth part heavier than their bulk of water. After respiration, the specific gravity of the lungs with the air contained in them, I found in one experiment to be 0·94; i.e., the organs were about one-seventeenth part lighter than their bulk of water. Thus it is that a very small quantity of air will render these organs buoyant in water; and an alteration in the volume of the lungs sufficient for this purpose would not be perceptible to the eye. It will be understood that the specific gravity of the substance of the lungs is unchanged; the organs are rendered only apparently lighter by the air contained in their cells, on the same principle as a distended bladder. Hence it follows, that the same apparent diminution of specific gravity will take place whether the air be derived from respiration, artificial inflation, or putrefaction. It is on this property of the lungs that the application of what is termed the hydrostatic test, or the decimasis pulmonaris, is founded,—a subject which may be appropriately considered in another chapter.

Conclusions.—The general conclusions which may be drawn from the contents of this chapter are: —

1. That a child may be born alive and be criminally destroyed before it has breathed.
2. That the presence of any marks of putrefaction in utero proves that the child must have come into the world dead.
3. That the characters accompanying certain marks of violence may occasionally show that the child was living when the violence was applied to it.
4. That there are no certain medical signs, by which a child which has not breathed, can be proved to have been living when it was maltreated.
5. That a new-born child may be destroyed by the prevention of respiration during delivery.
6. That the proof of respiration shows that the child has breathed; not that it has been born alive.
7. That by taking together the colour, volume, consistency, absolute weight and buoyancy of the lungs, we may be able to draw an inference whether the child has or has not resired.
8. That the lungs increase in weight according to the degree to which respiration is established, and not necessarily according to the period which the child has survived birth.
9. That no reliance can be placed upon the test of Plouquequet, or the proportionate weight of the lungs to the body.
10. That no reliance can be placed upon the relative quantity of blood in the pulmonary vessels, or the relative proportion of fat contained in the pulmonary tissue, as evidence of respiration having been performed.

CHAPTER XL

Mode of employing the hydrostatic test.—The Hydrostatic test has been long known, and various opinions have been entertained relative to its efficiency and value. Many of the objections that have been urged to its use, appear to have arisen from a mistaken view of the evidence which it is capable of furnishing. The term "test" is decidedly improper, since there are numerous cases in which it does not enable us to decide whether a new-born child has come into the world living or dead. It is, however, for the sake of convenience, here retained. When the hydrostatic test is properly applied, and with a full knowledge of the exceptions to which it is exposed, it may afford in many cases good evidence whether a child has or has not respired. The mode of performing the experiment is extremely simple. Having removed the lungs from the chest, they should be placed, still connected by the trachea and bronchi, upon the surface of distilled or river water. If they sink it should be noted whether the sinking takes place rapidly or slowly. If they both sink, the two lungs should be tried separately; for it is sometimes found, that one, commonly the right, will float while the other will sink. Supposing that both lungs sink, it will then be proper to divide each into twelve or fifteen pieces, and place these pieces separately on water. If, after this, they all sink, the inference is, that although the child may have lived and survived its birth, there is no evidence of its having respired. On the other hand, the organs when placed on water may float; it should then be noticed whether they float high above the surface, or at or below the level of the water; sometimes they indifferently float or sink. These differences will
lead to a conclusion respecting the degree to which respiration has taken place. It will now be proper to separate the lungs, and determine whether the buoyancy be due to one or both. Each lung should be divided, as before, and each piece separately tried. If all the pieces float, even after firm compression, we have good evidence, \textit{ceteris paribus}, that respiration has been very perfectly performed. Should any of the divided portions sink in water either before or after compression, our opinion may be modified accordingly. Some have recommended that the lungs should be placed on water with the heart and thymus gland attached; but there appears to be no good reason for this, since it is as easy to form an opinion of the degree of buoyancy possessed by the lungs, from the readiness with which they float, as by observing whether or not they have the power of supporting these two organs.

\textbf{Incorrect inferences}—Such, then, is the method of employing the hydrostatic test in cases of infanticide. With regard to its use in medical jurisprudence, it should be observed that the floating of the lungs in water is not, as it is often incorrectly represented to be, a proof that a child has been \textit{born alive}; nor is the fact of their sinking in water, any proof that a child was \textit{born dead}. The floating, under the limitations to be now described, proves only that a child has \textit{breathed}; the sinking, either that it has \textit{not breathed}, or breathed but imperfectly. The fact of a child having been \textit{born} living or dead, has, strictly speaking, no relation to the employment of the hydrostatic test. There are, indeed, cases of infanticide which may be readily established without resorting to this test: all that the law requires is proof of a child having been born living,—whether this proof be furnished by the state of the lungs through the hydrostatic test, or in any other way, is of no moment. The signs of life are commonly sought for in the lungs, because it is in these organs that the changes produced by a new state of existence are first perceived; but this examination may be dispensed with, when the woman confesses that the child was born alive—when others have seen it manifest life by motion or otherwise after its birth; or lastly, in cases, where, without being seen, it has been heard to cry. The crying of a child has been admitted as evidence of live birth on several trials for infanticide; although, from what will be hereafter said, it is possible that a child may be heard to cry, and die before its body is entirely born. Among the \textit{objections} which have been urged to the employment of the hydrostatic test, we have first to consider those which concern the sinking of the lungs in water.

\textbf{Sinking of the Lungs from Disease or Atelectasis.}

It is said that the hydrostatic test cannot show whether a child has or has not survived its birth, because the lungs of children
that have lived for a considerable period have been observed to
sink entirely in water. In some instances this may depend on
disease, tending to consolidate the air-cells, as hepatisation or
scirrhous; in others, on edema or congestion: but these cases can
create no difficulty, since the cause of the lungs sinking in
water would be at once obvious on examination. The hepatised
portion of lung may be known by the firmness with which it
resists cutting with a knife, as also by the fact, that it is impos-
sible to distend it artificially with air. On the other hand, there
are cases in which the lungs appear healthy and unaffected: all
that we can perceive is, that they retain their fetal condition.
This is a very different state from that of hepatisation, because
the lungs may, in this case, be made to receive air by artificial in-
flation. It is remarkable that life should continue for many hours,
and sometimes even for days, under such a condition: but the
occasional existence of this state of the organs in a living child is
placed beyond all dispute; — the explanation of the causes upon
which it depends — how it is that a child may live and breathe
for hours or days, and no signs of respiration are discovered in
its body after death, is involved in great difficulty. The re-
searches of Dr. E. Jörg, of Leipzig, have however, thrown some
light upon the subject: and these may probably lead the way to
other discoveries in this obscure department of physiology. Some
of Dr. Jörg’s views are peculiar. He considers that the act of
parturition, as well as the duration of the process, has a material
influence upon the system of a child; and that these conditions
serve to prepare it for the efforts which it has to make in per-
forming respiration. (Die Fötuslunge, Grimma, 1885.) Sup-
posing the first inspirations made by a child to be, from any
cause, feeble or imperfect, then the organs will become only par-
tially distended; the remaining portions will preserve their fetal
condition. Dr. Jörg considers this as a positively diseased state
of the lungs in the new-born child, and he has given to it the
name of atelectasis (ἀτέλης “incomplete”; ἐκτρασις “expansion”).
It may proceed from various causes. He considers, that children
which are born after a very easy and rapid delivery are subject to
it; and thus it may be found in a mature, as well as in an im-
mature child. Any cause which much weakens the vital powers
of a child before its actual birth, may give rise to the occurrence
of this imperfect dilatation of the lungs. In this way it may be
due to long-continued pressure on the head during delivery, or to
bleeding from the cord. All the causes of asphyxia in a new-
born child, will, when operating only in a very slight degree, also
produce this atelectatic condition. When only a part of the
lungs is, in the first instance, distended with air the child may
not afterwards acquire sufficient strength to fill the remaining por-
tions; it may thus live on for some hours or days, respiring at
intervals, and becoming occasionally convulsed, in which state it
will probably sink exhausted and die. Jörg has remarked, that those portions of the lung which are not speedily distended by air, afterwards become consolidated or hepatized, so that all traces of their vesicular structure are lost. The length of time which a child survives will depend upon the degree to which its lungs have become dilated. This condition of the lungs is sometimes to be clearly traced to the diversion of the blood from these organs, by reason of the ductus arteriosus or foramen ovale remaining open after birth.

Life with partial distention of the lungs. — It is not necessary that the whole of the lungs should have received air, in order that a child should continue to live even for some months after its birth. Some years since, I met with the following case, which will serve to illustrate this statement. A child aged six months, had been, it was supposed, destroyed by suffocation. Upon opening the thorax, the viscera were found healthy; but the whole of the inferior lobe of the right lung was, so far as regarded colour, density, and structure, precisely like the lungs of a fetus,—no air having ever penetrated into it. It had become developed in size, but its vesicular structure was perfectly destroyed. When the whole of the lung was placed in water, it floated; but when the inferior lobe was separated, it immediately sank to the bottom of the vessel. I have no doubt that this was a case of partial atelectasis, such as is described by Jörg. The lobe had not received air in the first instance; and had become afterwards consolidated or hepatized, so that it could not be inflated. Dr. Albert met with a case, in which a child died thirty-six hours after its birth, having been attacked by convulsions at intervals during that time. On inspection the whole of the right and the lower lobe of the left lung were found to be in their fetal condition, and they immediately sank when immersed in water. There was no diseased appearance in the organs, and the undistended portions were easily filled by blowing air into them. (Henke's Zeitschrift, 1837, ii. 422.) M. Depaule found that in many cases in which children had died suddenly after breathing for several hours or days, there was no other morbid appearance to be perceived than an unexpanded condition of a large portion of the lungs. (Med. Gaz. xxxix. 283.)

Life with perfect atelectasis, or entire absence of air from the lungs. —It is quite necessary for a medical jurist to be aware, that this state of the lungs, which is here called atelectasis, is by no means unfrequent among new-born children, although attention has been only of late years drawn to the subject. When no portion of air is found in the lungs of a child, there is no test by which such a case can be distinguished from one where the child has come into the world dead. These cases of atelectasis are ordinarily set down as exceptions to a very general rule; but I believe they are more common than some medical jurists are inclined...
to admit. In examining the body of a child, the history of which is unknown, it is proper that the possible occurrence of these cases should be well borne in mind. It appears to me not improbable, that many such come yearly before coroners in this country; and that they are dismissed as cases of still-born children, notwithstanding that marks of violence are often found upon the bodies. If, as it has been already observed, the lungs sink in water, the fact is commonly regarded as sufficient evidence of still birth. This is assuredly putting the most humane interpretation on the circumstances, and so far the result is not to be objected to; but we should take care, in carrying out this principle, that we do not throw obstacles in the way of judicial inquiry, and lead to the concealment of crime. Professor Bernt met with an instance in which a seven-months' child died two hours after birth; and when its lungs were divided and placed in water, every fragment sank. Remer has reported another, in which the lungs sank in water, both entire, as well as when divided, although the child had survived its birth at least four days. (Henke, Lehrbuch der G. M. p. 374.) In this case, the navel-string separated naturally before death. Orfila found, in a child which had lived eleven hours, every portion of the lungs, when divided, to sink on immersion. In three other cases, in which the subjects survived birth, four, six, and ten hours, the lungs also sank when divided; two of these were mature children. (Méd. Lég. i. 375.) In a case reported by Dr. Vernon,—a six-months' child cried loudly at intervals after its birth. It died in five hours. On examining its lungs they were not crepitant; they sank in water entire and when divided into small pieces. Under the microscope there was no appearance of air in any part. (Lancet, Feb. 3, 1855, p. 121.) Metzger supposed that premature children alone were likely to present this anomaly; i. e. of continuing to live after birth without leaving any clear signs of respiration in their lungs.

I may add to these instances, two which have occurred under my own observation. In one, the case of a mature male child, the lungs sank in water, although the child had survived its birth during a period of six hours. In the other, the case of a female twin, the child survived twenty-four hours; and after death the lungs were divided into thirty pieces; but not a single piece floated; showing, therefore, that although life had been thus protracted, not one-thirtieth part of the structure of the lungs had received from respiration sufficient air to render it buoyant. (Guy's Hospital Reports, No. v. p. 355.) In the latter instance no particular remark was made during life respecting the respiration of the child. These cases show most clearly that buoyancy of the lungs is not a necessary consequence of a child having lived and breathed for some time after birth. Probably, had this been a case calling for medico-legal inquiry, the lungs would have been cut to pieces; the sinking of the divided pieces in water,
either before or after compression, would have been set down as
negating the act of respiration, and, unless other strong evi-
dence were forthcoming,—the fact of the child having survived
its birth. Here, again, we perceive the necessity of not hastily
assuming that a child has been born dead, because its lungs sink
in water. There may be no good medical evidence of such
a child having lived after birth, but assuredly the mere sinking
does not warrant the common and positive dictum, that the child
was necessarily dead when born; it would be as reasonable to
pronounce, in a question of poisoning, that the fact of an indi-
vidual having died from poison was negatived by the non-dis-
covey of a poisonous substance in the stomach of the deceased.

Hydrostatic test not applicable to such cases.—It must be ap-
parent, on reflection, that cases of this description are beyond the
reach of the hydrostatic as well as of all other tests applied to the
respiratory organs; because the lungs do not receive and retain
a perceptible quantity of air, although the subjects may have lived
some hours. The hydrostatic test is no more capable of
showing that such subjects as these have lived, than it is of indi-
cating from what cause they have died. Facts of this kind de-
monstrate that a passive existence may be for some time continued
under a state of the respiratory process not to be discovered
after death. In the opinion of some, these cases form a serious
objection to the hydrostatic test; but it is difficult to understand
how they can affect its general application,—or why, because
signs of respiration do not always exist in the lungs of children
which have lived, we are not to rely upon them when they are
actually found. Poison is not always discoverable after death
in the stomach of a person who has taken it; but this does not
prevent a medical jurist from searching for it, and, under proper
precautions, relying upon its discovery, as evidence of poison-
ing in another case. These singular instances prove that we are
greatly in want of some sign to indicate life after birth, when the
marks of respiration are absent. Until we discover this, we must,
of course, make the best use of that knowledge which lies at our
disposal; taking care to apply it to those cases alone to which
experience shows it to be adapted. In the meantime, the com-
mon inference that a child had been born dead because its lungs
sink in water, is never likely to implicate an innocent party; it
can only operate by sometimes leading to the liberation of the
guilty.

Erroneous medical evidence from sinking of the lungs.—From the
cases already reported, it is a fair subject of consideration whether
a great error is not committed by those medical practitioners who
pronounce all children to have been born dead, merely because
the lungs contain no air and readily sink when placed on water.
This, it is true, is the common opinion, but it is not warranted by
observation. We are only entitled to say, in all such cases, that.
there is no evidence of a child having breathed or lived. Many might be disposed to consider it an unnecessary degree of refinement, to hesitate to express an opinion that a child was born dead when its lungs sank entirely in water, because certain cases have occurred wherein these characters have been possessed by lungs taken from the bodies of children that have survived their birth many hours. To those inclined to adopt this view, I would say, the answer to such a question is of far greater importance in a medico-legal, than in a medical light. In the latter case, no responsibility can be attached to the expression of the opinion commonly adopted; in the former case, however, when the question refers to child murder, a serious responsibility attaches to a practitioner; and he can only guard himself from unpleasant consequences, by basing his evidence on carefully observed facts. If a child can live for six or twenty-four hours, without its lungs receiving sufficient air to allow even one-thirtieth part of their substance to float, it is clear that such a child may be the subject of a murderous assault; and if a medical practitioner, losing sight of this fact, proceed to declare from the lungs sinking in water, that the child must have been born dead, his assertion may afterwards be contradicted, either by circumstances, by the testimony of eye-witnesses, or by the confession of the woman herself. He will be required, perhaps, to revise his opinion; and he will then find, that the fact of the lungs sinking in water is rather a want of evidence of life after birth, than a positive proof of a child having been born dead. It cannot be denied, that the sinking of the lungs is a presumption in favour of still birth, but it is nothing more;—it is not, as it is often set down, a direct or positive proof of a child having been born dead. There are many cases reported which show that this is not an unnecessary caution. Meckel relates two instances in which the lungs sank in water, but the women respectively confessed that they had destroyed their children; according to the general rule, these children must have been born dead, and no murder could have been committed! (Gerichtl. Med. 365.) For other examples of a similar kind, I must refer to the following journals. Ann. d'Hyg. 1837, i. 437; also, 1841, 429; Henke's Zeitschrift, 1840, xxvii. Erg. H.; Brit. and For. Med. Rev., Jan. 1842, p. 250. The cases there reported appear to me to convey a serious warning to medical witnesses, on the danger of expressing an opinion not strictly warranted by the medical facts, and which must be in such cases merely speculative. A case of some interest in this point of view has been communicated to the Medical Gazette, by Dr. Davies, of Hertford. In November, 1847, he was required to examine the body of a child found under suspicious circumstances. It was in a pasteboard-box of small size, with the lid turned inside out, and on the top there was a quantity of mould. The body was found buried in a garden. It turned out on inquiry that
there had not been exactly a concealment of birth on the part of the mother, who was an unmarried woman. The body was thirteen inches long from crown to sole; eyelids were adherent; testicles (it was a male child) had not descended; it weighed one pound and three-quarters. It was ascertained that it had been buried a fortnight, which accounted in some degree for the lightness of its weight in proportion to its length, and for a slight peeling off of the cuticle from some parts of the arms: the body looked otherwise healthy. The age was probably about seven months. On examining the lungs, they were found to be quite firm, like the liver; they sank in water both wholly and in parts. The right lung was of a dark brown mahogany colour, but the upper lobe of the left was of rather a lighter colour than any other part of the lungs. However, this lobe sank immediately upon being placed on water. The evidence at the inquest proved that the child was not only born alive, but that it had lived ten minutes at least, and perhaps longer, after birth. It appeared that an elderly woman, living close by, was sent for, and when she arrived she found the child, with the placenta attached to it, in the close-stool. She noticed that the child moved its arms; she therefore took it up with the placenta, and wrapped it in flannel. It continued to move its limbs for ten minutes, according to her account, but it uttered no cry. When the child ceased to move she divided the cord seven inches from the body, and tied it into a knot. (Med. Gaz. xl. 1022.)

It has been recommended that medical jurists should consider as dead every child that has not breathed, i.e. whose lungs sink in water; but they who give this advice at the same time admit that children may come into the world living without breathing, and the law holds, under the decisions of its expounders, that respiration is only one, and not an exclusive, proof of life. In order to establish life or even live birth, respiration need not always be proved, either in civil or criminal cases. (See post, BIRTH.) A medical jurist would therefore be no more justified in asserting that all such children were necessarily born dead, than that they were born living: and in stating what is the plain and obvious truth, it is not possible that his statement can ever be the means of involving an innocent person. It is certain, however, in departing from the truth, and stating what is contrary to well-known facts, that when the lungs of a child sink in water, it is safe and just to consider such child as having been born dead, he is incurring the risk of exculpating a really guilty person; for it cannot be too strongly borne in mind, that a woman is not charged with murder, merely because the lungs of a child float or sink in water, but because there are upon its body marks of violent injuries apparently sufficient to account for the death of a new-born child, or there are very
strong moral presumptions of her guilt. (See Ann. d’Hyg. 1836, ii. 362.)

FLOATING OF THE LUNGS FROM OTHER CAUSES THAN RESPIRATION.

Another series of objections has been urged to the hydrostatic test, based on the fact that the lungs may receive air and acquire buoyancy from other causes than respiration. These causes are two: putrefaction and artificial inflation. It was supposed, that the lungs of a still-born child might become emphysematosus from a compression of the sides of the thorax during delivery; but it is difficult to understand how in this way air should be extricated from these organs any more than it would be from the liver under similar circumstances. The truth probably is that what has been described as emphysema of the lungs in still-born children was nothing more than partial or imperfect respiration performed during delivery. In examining the bodies of many still-born children, I have never met with any appearance resembling what has been described as a state of emphysema independently of respiration and putrefaction. It may be proper, however, to state, that according to some observers, emphysema of the lungs may be produced under the following circumstances:—The thorax of the child is compressed in passing the outlet,—the lungs within are thereby compressed; and if this compressing force be suddenly removed, as by the thorax escaping, the elasticity of the parietes will cause the chest to expand, and air, it is presumed, will enter as a necessary consequence. The simultaneous compression of the abdomen might aid in the entrance of the air. (Lancet, May 20, 1837; also, June 17, 1837.) It is contended that not only may respiration take place during birth, but that even the lungs of the dead fetus may become thus mechanically inflated, and respiration be thereby simulated.

This opinion appears to be founded on an erroneous view of the condition of the thoracic viscera in the chest. The lungs, before air has entered into them, are as dense as the liver. If they be compressed they may become elongated, but when that pressure is removed, they will, if the child be dead, simply return to their original fetal condition. To suppose that they would expand and receive air, is to suppose that the reaction of the thoracic parietes is greater than the force with which they have been compressed. But what is to carry the thorax of a dead child beyond the point at which equilibrium is restored? Besides, this would not suffice to distend the air-cells, which are yet coiled up as it were and condensed. If this view were correct, scarcely a child would be born without having air in its lungs. In experimenting on this subject, I have never observed the least portion of air to enter;—the air-cells of the lungs do not therefore ap-
pear to be in the condition of spiral strings, which this hypothesis would represent.

**Floating of the lungs from putrefaction.**—The lungs of a still-born child, when allowed to remain in the thorax, are slow in undergoing putrefaction; but nevertheless, they sooner or later acquire sufficient air to render them buoyant in water. This form of gaseous putrefaction may even take place in the lungs of a child which has died in utero. One instance of the kind is recorded by Dr. Albert (Henke's Zeitschrift, 1837, ii. 179), in which the child was cut out of the uterus in a putrefied state, and its lungs floated when placed on water. It has been also alleged, that the formation of air may take place in the lungs from putrefaction, without this being indicated by change in colour, smell, or other properties of the organs; but admitting that this may occur, it can create no difficulty in the investigation.

When the lungs are putrefied, this will be determined, in general, by putrefaction having extended throughout all the soft parts of the body. The organs, according to the degree of putrefaction, will be found soft, of a dark green or brown colour, and of a highly offensive odour; the serous membrane covering the surface will be raised in large visible bladders, from which the air may be forced out by very moderate compression. It has been remarked, that, under the same conditions, gaseous putrefaction takes place as rapidly in the liver, heart, and thymus gland of a new-born child, as in the lungs. We should therefore examine the general conditions of the body; the distension of the lungs with gas from putrefaction cannot be easily overlooked or mistaken for the air of respiration. The answer to any objection founded on the putrefied state of these organs, must at once suggest itself. It is impossible that any well-informed medical witness can expect to obtain satisfactory evidence from experiments on the lungs of such subjects. He should at once abandon the case, and declare that in regard to the question of respiration, medical evidence cannot establish either the affirmative or the negative. The fact of his not being able to give the evidence required, cannot be imputed as a matter of blame to him; because this is due to circumstances over which he has no control. In a case of poisoning, the appearances after death in the viscera may be entirely destroyed by putrefaction; but no practitioner would think of looking for proofs when the circumstances rendered it utterly impossible for him to obtain them.

A case may possibly occur wherein the characters presented by the lungs will be such as to create some doubt whether the buoyancy of the organs be due to putrefaction or respiration, or, what is not unusual, whether the putrefied lungs may not also have undergone the changes of respiration. The facts may be apparently explicable on either assumption. Even here a proper investigation may serve to remove all doubt. (See case by Dr.
Francis, Med. Gaz. xxxvii. 460.) It has been recommended on
these occasions that the witness should lean to the side of the
prisoner,—in other words, he should give an opinion, that the
child suspected to have been murdered had not expired. This
advice is equal to recommending a witness to take upon himself
the duty of a jury, and virtually to acquit a prisoner upon a
doubt existing in his own mind, in respect to only one portion
of the evidence adduced against her. The evil effects of following
this kind of advice are well shown by a case reported in Henke's
Zeitschrift (1843, i. 102, Erg. H.), in which an opinion was improp-
erly given by a medical witness, that the child, the whole of the
organs of whose body were in an advanced state of putrefaction,
was born dead; and the prisoner afterwards confessed that it had
been born living! This shows that it is always better to leave a
doubtful case as we find it, than to express a positive opinion
on one side or the other, when this opinion can never amount to
more than a conjecture. If a witness were simply to assure the
jury, that medical evidence could not solve the question whether
the child had lived,—if he were to assert, what is really the fact,
that his experiments would not allow him to say whether the
child had or had not expired,—it is certain that no innocent
person would ever be convicted or a guilty person acquitted, upon
his evidence. It is for a jury only to judge of guilt from all the
circumstances laid before them; but it is assuredly not for a
medical witness to prevent all further investigation, and put an
end to the case, by leaning to the side of the accused when there
is really a doubt upon his mind. It is his duty to state that
doubt, and leave the decision of guilt or innocence in the hands
of the Court.

Conclusions.—The general conclusions which may be drawn
from the contents of this chapter, respecting the application of
the hydrostatic test in cases of infanticide, are the following:—
1. That the hydrostatic test can only show whether a child has
or has not breathed, it does not enable us to determine whether
a child has been born living or dead.
2. That the lungs of children which have lived after birth
may sink in water owing to their not having received air, or to
their being in a diseased condition.
3. That a child may live for a considerable period when only
a portion of the lungs has been penetrated by air.
4. That a child may survive birth even for twenty-four-hours,
when no part of its lungs has been penetrated by air.
5. Hence the sinking of the lungs (whether whole or divided)
in water is not a proof that a child has been born dead.
6. That the lungs of children which have not breathed and
have been born dead, may float in water from putrefaction or
artificial inflation.
7. That the lungs as situated in the chest undergo putrefaction
Floating of the lungs from artificial inflation.—It has been alleged that the lungs of a still-born child may be made to assume, by artificial inflation, all the characters assigned to those which have undergone respiration. Thus, it is said, a child may not have breathed, and yet the application of the hydrostatic test would in such a case lead to the inference that it had. It will be seen that the force of the objection goes to attack directly the inference derivable from the presence of air in the lungs. This objection can, it appears to me, be admitted only under one form, namely, as it applies to lungs which have been inflated while lying in the cavity of the chest. Any experiments performed on inflation after their removal from this cavity, can have no practical bearing; since in a case of infanticide we have to consider only the degree to which the lungs may be inflated by a person who is endeavouring to resuscitate a still-born child. The difficulty of inflating the lungs of a new-born child is too well known to require to be here adverted to; the greater the violence used, the less likely is the air to pass into these organs, but it rather finds its way through the oesophagus into the bowels. Dr. Albert, a late writer on the subject, denies that the organs while lying in the chest can be so filled with air, either by the mouth or by means of a tube, as to be rendered buoyant in water. In performing this experiment several times, he never found a trace of air in the air-cells; and he contends that medical jurists have begun at the wrong end (den Gaul von hinten aufge-zielt), in endeavouring to seek for answers to an objection, before they had ascertained that such an objection could have, practically speaking, any valid existence. (Henke, Zeitschrift, 1837, ii. 390.) M. Depauli has still more recently found that

*FLOATING OF THE LUNGS FROM INFLATION. 455*

very slowly,—that if but slightly putrefied, the air may be easily forced out by compression, and if much putrefied, either the case must be abandoned, or other sources of evidence sought for.

**CHAPTER XLI.**

**FLOATING OF THE LUNGS FROM ARTIFICIAL INFLATION. INFLATION DISTINGUISHED FROM PERFECT RESPIRATION—NOT DISTINGUISHABLE FROM IMPERFECT RESPIRATION—DOUBTFUL CASES—RESULTS OF COMPRESSION—IMPROPER OBJECTIONS TO THE HYDROSTATIC TEST—SUMMARY—RESPIRATION BEFORE BIRTH—VAGITUS UTERINUS—RESPIRATION A SIGN OF LIFE, NOT OF LIVE BIRTH—THE KILLING OF CHILDREN WHICH BREATHE DURING BIRTH NOT CHILD-MURDER. GENERAL CONCLUSIONS.
requires great force to inflate the lungs, and that their resiliency was sufficient to expel the greater part of the air introduced. (Med. Gaz. xxxix. 283.)

Having had several opportunities of examining the lungs of children in which inflation had been resorted to, not for the express purpose of creating an objection to the hydrostatic test, but with the bonâ fide intention of resuscitating them, I may here state the results. In some of these instances a tube had been used, and in others the mouth. In the first case it was found on inspection, that only about one-thirteenth part of the structure of the lungs had received air. In the second, no part of the lungs had received a trace of air, although inflation had been repeatedly resorted to; the air had passed entirely into the abdomen. In a third, attempts were made for upwards of half an hour to inflate the organs; but, on examination, not a particle of air was found to have penetrated into them. In a fourth, no air had entered the lungs, and in a fifth, although a small portion had penetrated into the organs, it was readily forced out by compression. In repeatedly performing experiments on dead children, the results have been similar; the lungs, after several attempts, were found to have received only a small quantity of air. Thus, then, it would appear, that the lungs of a new-born child may be inflated in situ, although with some difficulty, and that the quantity of air which they receive under these circumstances is inconsiderable. If the efforts at inflation be continued for some time in the dead body, and the tube be violently introduced into the larynx or trachea, or if the organs be inflated after removal from the chest, with the express intention of causing them to resemble respired lungs, the result is different: but this is not the mode in which the objection can possibly occur in a case of infanticide,—a circumstance which appears to have been strangely overlooked by some of those who have examined this alleged objection to the hydrostatic test. It is not likely that a woman, if able to perform the experiment at all, would be capable of doing more than a practised accoucheur; and the probability is, that she would, in general, altogether fail in the attempt. One case is recorded, in which a woman, recently delivered, is stated to have succeeded in artificially inflating the lungs of her child (Meckel, Lehrb. der G. M. 368:—see also Ed. Med. and Surg. Jour. xxvi. 374); and another, in which this defence was urged on the part of a female, is reported by Dr. von Siebold, of Göttingen (Henke's Zeitschrift der S. A. iii. 1845). The child, in this instance, was found with its head cut off, and the lungs contained air. The inconsistency of the woman's statement as to the mode in which she inflated the lungs was clearly proved, and the examiners did not hesitate to give a decided opinion that the air found in the lungs had been derived from the act of respiration, and not from artificial inflation. The whole case shows
clearly that when a theoretical objection of this kind comes to be tested practically, it ceases to present any difficulty.

But let it be admitted that the lungs are artificially inflated; in this case, they would resemble, by their partial distension with air, and other physical characters, those of children which had imperfectly breathed. Like them, they may float on water; but on cutting them into pieces, some of these would be found to sink. If the pieces be firmly compressed either by means of a folded cloth or between the fingers, they will lose their air and sink; so that in fact there are no physical means of distinguishing artificially inflated lungs from those that have imperfectly breathed. Experiment has repeatedly shown that when respiration has been feeble, and no artificial inflation resorted to, the air may be forced out of the lungs by moderate compression, and the portion so compressed will sink in water. If the compression be produced under water, bubbles of air may be seen to rise through the liquid. The results have been exactly the same when the lungs were inflated artificially as they were lying in the chest. (See Guy's Hospital Reports, No. V., and for some good remarks on this subject by Dr. Christison, see Ed. Med. and Surg. Jour. xxvi. 74.)

Artificial inflation distinguished from perfect respiration. — If respiration has been perfectly established, and the lungs are well filled with air, it is impossible so to expel this air by compressing the divided portions of the organs, as to cause them to sink in water. It has been asserted, that it is equally impossible to force the air out of lungs that have been artificially inflated; but it is highly probable that in these cases the lungs had been inflated to a maximum degree when removed from the thorax, a case in which much difficulty is certainly experienced in expelling the air; but this is not the form in which the objection can ever present itself in a case of infanticide. If the lungs be inflated in the ordinary way, i.e. while lying within the chest, there is never, according to my observation, any great difficulty in causing them to lose their air by compression,—a result which has been repeatedly demonstrated to the medico-legal classes of Guy's Hospital. Although no reliance can be placed on the effects of compression in cases of imperfect respiration, yet it appears to me that when with great weight of the lungs, there is great buoyancy in water, the fact of these organs not losing the air contained in them, and not sinking after very firm compression, ought to be considered as a good corroborative proof of the child having breathed. It has been just stated that compression will not extricate air from lungs which have fully respired. By this, it is not to be understood that the experiment of compression can only be practically applied, to distinguish respiration in those cases in which a child has lived for a considerable time after its birth. I have found it to succeed, even where a child had lived to make its
more than one or two respirations, and had died before it was actually born. In this case, it was found necessary, in order to effect delivery, to destroy the child while the head was presenting. It lived, however, a sufficient time after the protrusion of its head with the greater part of the brain destroyed, to cry loudly for an instant. The general appearance of the body showed that it had attained to the full period of gestation. On opening the thorax, the lungs were seen projecting slightly forwards over the sides of the pericardium. They were of a light-red colour, but not crepitant under the finger. They had the external physical characters which these organs are known to acquire on the first establishment of respiration; but the absence of crepitation proved that the process could not have been perfectly performed. The colour of the external surface was throughout uniform; a circumstance which I have never witnessed in lungs that had been artificially inflated, except when the inflation had been carried to its fullest extent out of the body. Then, however, there is, commonly, distinct crepitation. When removed and placed on water, these organs floated freely; and on being separated, both appeared equally buoyant. Each lung was next divided into sixteen pieces, and every piece floated. In dividing them, it was observed that the colour was uniform throughout their substance; there was no sense of crepitation or crackling under the knife; and the cells, in which the air was diffused, could not be seen. The pieces were then subjected to forcible compression, for some time in a folded cloth. The cloth was ruptured by the force employed; yet on removing the pieces, and placing them on water, they all continued to float. A portion of air had, undoubtedly, been forced out, but not sufficient to deprive any of them entirely of their buoyancy. By this we learn that in some instances two or three respirations only may suffice to stamp upon the lungs characters whereby they may be easily distinguished from those organs that have undergone artificial inflation. The compression was carried to the furthest possible limit consistently with the preservation of the organic structure of the lungs.

It must not be supposed, that, in all children which have lived but a second or two to respire, similar results will be obtained. The respiration of an instant may distend the lungs of one child, as much as respiration, continued for several hours, would those of another. The time which a child has survived its birth does not allow us to predict to what degree its lungs will be found distended on inspection, or what the results of experiments on these organs will be. A child may have feebly expired, and have died either in a few minutes or hours, or not until many days have elapsed after its birth. There is, of course, no definite boundary between the perfect and imperfect distension of the lungs, but by the latter condition we may understand that state of the healthy organs in which they contain only sufficient air to
render them buoyant in water; and from the slight difference in their specific gravity and that of water, a very small quantity will suffice for this. In these cases, the colour, volume, and consistency of the lungs are scarcely changed from the natural condition. The admission that air may be compressed out of feebly respired lungs by the same means as out of those which have been submitted to artificial inflation, may appear to render compression useless, as a distinguishing sign of artificial inflation; but we must not forget, that other corroborative sources of evidence may be forthcoming. The experiment of compression will, I believe, when properly applied, enable us to distinguish cases of complete respiration from those of artificial inflation of the lungs in situ; and, if for this circumstance alone, it ought to be regarded as an adjunct occasionally useful in these investigations.

Artificial inflation not distinguishable from imperfect respiration. —It must, however, be admitted, that there are no means of distinguishing feeble respiration from artificial inflation. The physical characters of the lungs will be unaltered; and compression will, in either condition, destroy their buoyancy. In a case of this kind, I apprehend the only course left open to a medical witness is, to state to the jury, that the evidence derived from experiments on the lungs left it uncertain whether the child in question had expired, or had had its lungs artificially inflated. The jury will then know how to return their verdict; for it must be remembered, they have always circumstances to guide their judgment, as well as medical opinions; and it is upon the whole, and not upon a part, of the evidence laid before them, that their verdict is founded. It is singular that this occasional difficulty of distinguishing artificial inflation from respiration, should have been represented as a serious objection to the employment of the hydrostatic test. Even admitting, in the very few instances in which such a defence on the part of a prisoner is possible, that a practitioner is unable to distinguish the one condition from another, this becomes purely a point for the consideration of a jury; it cannot affect the general application of the hydrostatic test. Examples of this sort of difficulty are by no means uncommon in the practice of medical jurisprudence. Many instances might be adduced of medical evidence being rendered doubtful by circumstances wholly independent of the skill of the practitioner, and over which he has no possible control. In the determination of any single point in a case of child-murder, whether it relate to live birth or the actual cause of death, a doubt may arise; the question relative to the respiration of a child is not exempted from this rule; but it would be the height of inconsistency to contend, that, because certain means of investigation will not always enable us to express a positive opinion, we should never have recourse to them. I presume that, in the present day, no practitioner would trust to the floating of the lungs as a sign of
breathing, before he had ascertained that the air contained in them could not be expelled by compression. The charge against an accused party is not likely, therefore, to be sustained by medical evidence of the respiration of the child, unless the child have actually expired; but it is possible, that owing to a want of evidence to characterise feeble respiration, a really guilty person may escape upon the bare assumption that the lungs might have been artificially inflated. The mischief to be apprehended is not then, as it has been often alleged, that the employment of the pulmonary test may lead to the condemnation of an innocent but rather to the acquittal of a guilty person. This is certainly an unfortunate result; but it is one for which medical science is not yet in a condition to provide an adequate remedy.

In reference to this objection, there are, it appears to me, only two cases which may give rise to some doubt respecting the source of the air contained in the lungs of a new-born child.

**Doubtful cases.**—1. In the case of a child that has not breathed the lungs may be disproportionately heavy, weighing nine hundred to one thousand grains, and they may have been artificially inflated in the attempt to resuscitate it. Unless, in this case, the air were expelled by compression, an inference might be hastily drawn, that the child had probably breathed. The error could be removed only by circumstantial evidence: which, however, is generally sufficient to remove a speculative objection of this kind. But unless the foetal lungs were highly congested, diseased, or of extraordinary size, it is not likely that they would weigh so much as is here supposed. These doubtful cases may always be suspected to exist when, with considerable absolute weight, the lungs contain very little air. Let us, however, consider what would be its practical bearing on the question of child-murder supposing the case not to be cleared up by any of the methods above suggested. 1st, The fact of respiration would not be clearly proved because the great absolute weight of the lungs, without their structure being permeated with air, amounts to nothing. 2ndly, Although the proof of respiration might not be made out this would not show that the child was born dead; for we know that a child may live many hours, and yet no evidence of life may be derived from an examination of the lungs. 3rdly, Admitting that there was proof of the child having lived after birth whether there were evidence of respiration or not, the cause of death would have still to be made out: and unless this be clearly traced to the wilful and malicious conduct of the prisoner—proofs of which are not likely to be derived from the body of a child whose lungs she has innocently inflated—she must be acquitted. Thus, then, it is difficult to understand how, in the hands of one who has attended to the subject of infanticide—and no others ought to be allowed to give medical evidence—the objection, on the ground of inflation, can lead to any difficulty.
whatever in practice. Such a case as that which I have here supposed actually occurred to me in June 1842. A male child, weighing upwards of twelve pounds, died during delivery in a difficult labour. It gave no signs of life when born, and there was no pulsation in the cord. Its lungs were artificially inflated in the attempt to resuscitate it. The organs weighed nine hundred and ninety-four grains. They were slightly crepitant and floated on water, but gentle pressure by the fingers caused them to sink. It was clear that the increased weight depended on their great size, and not on any change produced by respiration. They contained but a very small quantity of air, which was easily expelled by pressure. In another case, which I examined in June 1847, the child was born dead. The body was well developed, and the lungs weighed 784 grains. These organs were inflated as they were lying in the chest. On moderate compression, when divided, they immediately sank in water.

2. We will now take the converse objection. A child may live and breathe, and its lungs weigh much under the average of respired lungs, i.e. about seven hundred grains. In a case like this, unless the air resist expulsion by compression, a converse mistake might be made, and we should pronounce a child that had really breathed and survived birth, to have been still-born and to have had its lungs artificially inflated. This might happen in numerous cases of imperfect respiration after birth, did we not know that the sinking of the lungs, whether containing air or not, and whether this air be expelled by compression or not, does not necessarily prove that the child was born dead. It can only show, under the most favourable circumstances, that it has either not respired, or respired imperfectly. The sinking of the lungs may take place in a child that has survived birth and has really been murdered; but in such a case, there may be no proofs of life; and therefore a person actually guilty of a crime, would be discharged for want of sufficient medical evidence to convict. This, however, could no more justify the entire abandonment of medical evidence in such cases, than it could of general evidence; because this, like evidence which is purely medical, is but too often insufficient to bring home guilt to the really guilty. The objection, therefore, on the ground of artificial inflation, when closely examined, is more speculative than real. Admitting, as some contend, that there is no positive criterion to distinguish this condition from respiration, it is difficult to conceive a case in which the objection could be sustained; and, if sustained, it never could lead, in the hands of proper witnesses, to the inculcation of the innocent:—unfortunately for society, it would only add another loop-hole to the many which, through the necessary forms of law, now exist, for the escape of the guilty.

Results of compression.—It is proper to observe, that the results obtained by submitting the lungs to compression in cases
of respiration and artificial inflation, have been very different in
the hands of experimentalists equally competent. Some state that
they have been able to force out the air in both instances,—other
in neither case. These discrepancies may depend either upon the
different degrees of pressure employed, or upon the actual degree
distension of the lungs. The fact of their existence shows, at
least, that the lung-tests cannot be safely trusted in the hands of
persons who have not been used to such investigations. It appears
to me that there has been a great deal of misplaced discussion on
this subject. One case should at least be adduced, where a
woman charged with child-murder has been or can be hypotheti-
cally exposed to any risk of conviction from the admission that
air cannot by compression be forced out of artificially inflated,
or that it can be expelled from respired lungs. I am not aware
that there is a single instance in our law records, of such an ob-
jection being raised upon any but merely hypothetical grounds,
in opposition to all the circumstances of' the case. It might be
imagined, however, from the discussions among medical writers
on the necessity for certain and infallible means of distinguishing
artificial inflation from respiration, that every woman tried
for child-murder had made the praiseworthy attempt to restore
a still-born child, although circumstances may show that she
had cut its throat, severed its head, or strangled it, while cir-
culation was going on! (See case, Prov. Med. Journal, April 23,
1845.) If compression be trusted to as a criterion, without a
proper regard to other facts, a practitioner not used to such cases
may undoubtedly be easily led into error; but he may be equally
deceived if he trust what has been proposed as a substitute for
compression—i.e. a mere physical inspection of the lungs.

_Improper objections to the hydrostatic test._ Summary.—In con-
closing these remarks upon the objections to the hydrostatic
test, it may be observed that medical practitioners have differed
much at different times in their ideas of what it was fitted to
prove. About fifty years ago, it would seem that this test was
regarded by some as capable of furnishing evidence of murder!
Thus we find Dr. Hunter asking the question, "How far may we
conclude that the child was born alive, and probably murdered by
its mother, if the lungs swim in water?" Later authorities,
and, indeed, many in the present day, assert that the test is ca-
pable of proving whether a child has been _born alive_ or not?
From what has already been stated, as well as from the most
simple reflection on the circumstances accompanying the birth
of children, I think it must be evident that the hydrostatic test
is no more capable of showing whether a child has been _born alive
or dead_, than it is of proving whether it has been murdered or
died from natural causes. The majority of those who have
made experiments on this subject have only pretended to show,
by the use of this and other tests, whether or not a child has
breathed,—they merely serve to furnish in many cases good proof of life from the state of the lungs: and slight reflection will render it apparent that in no case are they susceptible of doing more. Even here their utility is much restricted by numerous counteracting circumstances, a knowledge of which is essential to him who wishes to make a practical application of the facts connected with them. (See Ed. Med. and Surg. Jour. xxvi. 365.) If asked to state in what cases the pulmonary tests are capable of assisting a medical jurist, the answer, it appears to me, would be: 1st. They will clearly show that the new-born child has lived, when, during its life, it has fully and perfectly respired. Cases of this description form a certain number of those which come before our Courts of law. To them, the most serious objections are not applicable; and the few which might be made to the medical inferences are not difficult to answer. 2dly. They will allow a witness to say, that the lungs must have either received air by respiration, or by artificial inflation. These are the cases in which a child has died soon after birth, and where the respiratory changes are but very imperfectly manifested in the lungs. They probably form the large majority of those that fall under the jurisdiction of the criminal law. It might be considered, that the qualification in the inference here drawn would neutralise its force; but it must be remembered, that there are few instances of actual and deliberate child-murder, wherein artificial inflation could become even a possible defence for an accused party. So unusual is this kind of defence, that among the numerous trials for infanticide which have taken place in this country for many years past, I have not been able to meet with a single instance in which it was alleged, as an objection to the evidence derived from the buoyancy of the lungs, that the prisoner had inflated them in order to resuscitate her child. The reason is obvious; had such a defence been attempted, the whole of the circumstantial evidence would at once have set it aside. When, in the suspected murder of an adult, a medical man swears that a fatal wound was such that the deceased might have inflicted it on himself, or that the prisoner might have produced it, he is placing the jury in a position very similar to that in which he places them in a case of child-murder, when he says that the child might have breathed, or its lungs might have been artificially inflated. How would a jury decide in the two cases? Assuredly, by connecting certain facts with which a medical witness is not concerned, but which may, in their opinion, satisfactorily supply the place of what is defective in his evidence. It is not for him to speculate on the probabilities of respiration, or of artificial inflation; but it is for them to consider whether an accused party was or was not likely to have resorted to an experiment of this nature. It has been suggested, that some person might inflate the lungs of a dead child, in order to raise a charge
of murder against its mother; but this suggestion presupposes a profound knowledge of the difficulties of medical jurisprudence; and even then the question of murder does not happen to depend merely on the presence of air in the lungs. Such a case is very unlikely to present itself; indeed, its occurrence is no more probable than that in poisoning, it should be considered a good defence that some person might have introduced poison into the stomach after death. The circumstances of the case will commonly furnish a sufficient answer to such hypothetical views.

The hydrostatic test ought not, therefore, to be lightly condemned, or rejected upon a speculative objection, which, in ninetenths of the cases of child-murder, could not possibly exist. Let it be granted to the fullest extent, that a conscientious medical jurist cannot always draw a positive distinction between respiration and artificial inflation, still the jury may be in a situation to relieve him from the difficulty. In short, it would be as reasonable to contend that all murderers should be acquitted because homicidal are not always to be distinguished from suicidal wounds, as to argue that all cases of infanticide should be abandoned because these two conditions are not to be known from each other by any certain medical signs. If juries do frequently dismiss such cases, it is, I apprehend, to be ascribed rather to their great unwillingness to become the means of administering what they consider to be severe laws, than to their want of power to balance and decide on the probabilities laid before them. If the pulmonary tests were wholly set aside, it is easy to conceive what would be the consequences. Thus, let us suppose that a newborn child is found, under suspicious circumstances, with its throat cut: we are called upon to say, that it is impossible for medical evidence to establish whether the child had lived or not, and therefore we are to decline making an inspection of its body. But this would be the same as declaring that child-murder could never be proved against an accused party, and that newborn children might henceforth be destroyed with impunity! It appears to me, that conduct of this kind, on the part of a medical witness, would be wholly unwarrantable; for we may sometimes acquire, by an inspection, as great a certainty of respiration having been performed, and therefore of a child having lived, as of any other fact of a medico-legal nature. Cases of poisoning often give rise to greater difficulties to a medical jurist; as where, for example, he attempts to found his opinion of the cause of death on symptoms or the appearances in the dead body. But we may put the question in this light. In the body of a healthy full-grown child, which has but recently died, we find the lungs filling the cavity of the chest, of a light red colour, spongy, crepitant beneath the finger, weighing at least two ounces, and when divided into numerous pieces, each piece floating on water, even after violent compression. Is it possible in such a case to doubt that
respiration has been performed? If there is no certainty here, it appears to me that medical experience is but little fitted in any case to guide us in our inquiries. It would be difficult to point out an instance in which an affirmative medical opinion would be more surely warranted by the data upon which it was founded.

Respiration before birth.—It has been already stated that the pulmonary tests are fitted to prove only whether a child has or has not lived to respire. Neither the hydrostatic nor any other test can positively show that a child was entirely born alive when the act of respiration was performed. As this is a subject which generally gives rise to some discussion in cases of child-murder, I shall here make a few remarks on it:—1st, Respiration may be performed while the child is in the uterus, after the rupture of the membranes;—the mouth of the child being at the os uteri. This is what is termed vagitus uterinus; its occurrence, although extremely rare, seems to me to rest upon undisputed authority. 2ndly, A child may breathe while its head is in the vagina, either during a presentation of the head or the breech. This has been termed vagitus vaginalis. It is not very common, but it must be set down as a possible occurrence. 3rdly, A child may breathe while its head is protruding from the outlet: in this position, respiration may be as completely set up in a few moments by its crying, as we find it in some children that have actually been born, and have survived their birth for several hours. This is the most usual form of respiration before birth. In the vagitus uterinus or vaginalis, the lungs receive but a very small quantity of air; in respiration after protrusion of the head, the lungs may be sometimes found moderately well filled; although never, perhaps, possessing all the characteristic properties of those which have fully respired. The well-known occurrence of respiration under either of these three conditions strikingly displays the fallacy of making this process, as some have done, the certain criterion of uterine life. A child may breathe in the uterus or vagina, or with its head at the outlet, and die before its body is born: the discovery of its having respired would not, therefore, be any sort of proof of its having enjoyed what has been termed “extra-uterine life.” (For a well-marked case of this kind, see Med. Gaz. xxxviii. 394, and another communicated to me by Dr. Crothers, of Coy, will be found in Guy’s Hospital Reports, Oct. 1850, p. 231.) The death of a child which has respired in the uterus or vagina, from natural causes before its entire birth, is a possible occurrence; but its death from natural causes before birth, after it has breathed by the protrusion of its head from the outlet is, I believe, a very unusual event. All that we can say is—it may take place; but its death, under these circumstances, would be the exception to a very general rule. Oberkamp, in four successive deliveries of
the same female, observed that the children breathed before delivery, but died before they were born. A case of this kind also occurred to Diemerbrock. (See Meckel, Lehrbuch der G. M. p. 367; Beck's Med. Jur. vol. i. p. 498; also Ed. Med. and Surg. Jour. xxvi. 374.) The cases reported by Beck, of which there are three, lose much of their value from the fact that the lungs were not examined.

Respiration a sign of life, not of live birth. — The hydrostatic test is only capable of determining that respiration has taken place; it cannot show whether this process was established during birth or afterwards. The fact of a child having the power of breathing before it is entirely born, does not therefore constitute the smallest objection to its employment; although upon this ground, we find the use of it, in any case, denounced by many eminent members of the medical and legal professions. Thus, Archbold says, "Very little confidence is placed in this test as to the lungs floating, particularly if the child were dead any length of time before the experiment was made" (Criminal Pleading, 367); Mathews speaks of the test as being "quite exploded" (Digest, 251); and Jervis makes the same remark (On Coroners, 127). It is obvious that most members of the law who have treated the subject have adopted, without sufficient examination, the statements of Dr. William Hunter. This author observes: "A child will commonly breathe as soon as its mouth is born or protruded from the mother; and in that case, may lose its life before its body be born, especially when there happens to be a considerable interval between what we may call the birth of the child's head and the protrusion of its body. And if this may happen where the best assistance is at hand, it is still more likely to happen when there is none—that is, where the woman is delivered by herself." (On the Uncertainty of the Signs of Murder in the case of Bastard Children, p. 33.) Dr. Hunter here exposes, in plain language, the fallacy of trusting to signs of respiration alone, as evidence of a child having been born alive. The truth of his remarks is, in the present day, generally admitted; and if, among medico-legal writers, we find some still treating of respiration as a certain proof of live birth, it is from their not having sufficiently considered the probability of a child breathing, and dying before its body is entirely extruded. But we may ask, How does the admission of these views affect a case of deliberate child-murder? A living and breathing child may be wilfully destroyed before its body is entirely born, as well as afterwards; and if the law of England does not contemplate the wilful destruction of a living and breathing child, before its entire birth, as a crime, this omission cannot be imputed as a fault to the medical jurist; nor can it at all diminish the real value of the hydrostatic test as furnishing indisputable evidence of life. Most persons might consider the crime of murder sufficiently
made out, when the medical evidence showed that a child had lived, and that it was living when criminally destroyed. If, however, this does not constitute infanticide in law, and evidence be further insisted on, to set forth where the child was actually living when murdered—whether half protruding from the vagina, or altogether external to the body of the mother, then the fact of respiration before birth is an objection rather against the principles of the law, than against the test used to determine the presence of life. In a case tried a few years since, in which a child had been found with a ligature firmly tied round its neck, the medical evidence showed clearly that it had breathed; and the whole of the appearances in its body were such as to leave no medical doubt that it had died by strangulation. The judge, in charging the jury, said, "if they were of opinion that the prisoner had strangled her child before it was wholly born, she must be acquitted of the murder!" The prisoner was acquitted. However we may regard the question of the utility of pulmonary tests, we must look upon that law as but very imperfectly adapted to its purposes, which makes the proof of murder to rest, not upon the actual and wilful destruction of a living child, but upon the precise moment which a murderer may select for the accomplishment of the crime. Impunity is thus held out to all offenders, who destroy a living child during the act of birth; but there is an additional evil, accompanying the operation of this legal rule, which seriously affects the medical evidence given on these occasions. It would seem, from cases to be presently related, that the law will assume, until the contrary appear from other circumstances, that the respiration of a child, if proved by the best of evidence, was carried on before it was entirely born. Let the witness, then, in a case of alleged infanticide, ever so clearly establish the fact of respiration, and therefore of life, at the time the violence was used, this evidence is not sufficient. He is asked whether he will depose that the child had breathed after its body was entirely in the world. Unless he can make this deposition—which, for obvious reasons, he can rarely be in a condition to do—it will be presumed that, although the child had breathed, it came into the world dead. Hence, we perceive, a legal shield is effectually thrown around those who may have been really guilty of destroying their children immediately after birth. Under any moral consideration of the circumstances, it appears to me impossible to admit, that a woman who kills her child in the act of birth is less guilty of murder than she who chooses the moment of its entire expulsion to destroy it; and any such distinction, carried to its full extent, must virtually go to the entire abrogation of the law. It is quite necessary that medical witnesses should know what they are required to prove on these occasions; and the following cases will, perhaps, serve to place this matter in a clear light.
The killing of children which breathe during birth, not child-murder. — In the case of Rex v. Poulton, good medical evidence was given to show that the child was living when the violence was offered to it. Of three medical witness, who were called, the first said in answer to questions put to him: It frequently happens that a child is born as far as the head is concerned, and breathes, but death takes place before the whole delivery is complete. My opinion in this case is, that the child had breathed, but I cannot take upon myself to say that it was wholly born alive. The second said that death might have occurred when the child was partly born, if no medical man was present to assist in the delivery. The third witness said,—it is impossible to state when the child expired; but there is no doubt from the condition of the lungs, when they were examined, that the child had breathed: children may breathe during birth. (Chitty, Med. Jur. 412.) The evidence here given shows that the witnesses were intelligent men; and that they had duly reflected upon that which the hydrostatic test is really capable of proving. The judge held that this medical evidence was not sufficient: — "something more was required than to show that a child had expired in the progress of its birth; it must be proved that the whole body of the child was brought into the world." (See Mathews' Digest, Supp. 25; also, Archbold, Crim. Plead. 367.) In the case of Rex v. Simpson, tried at Winchester, in March 1835, Baron Gurney would not allow the case to proceed against a prisoner, so soon as the medical witness stated that the lungs of a child might become distended by the act of respiration during birth. In Rex v. Brain, it was held that the child must be wholly in the world in a living state to be the subject of murder; and in that of Rex v. Sellis (Norfolk Spring Circuit, 1837), Mr. Justice Coltman held, that to justify a conviction for child-murder, the jury must be satisfied that the entire body of the child was actually in the world in a living state, when the violence was offered to it. In relation to an important case of infanticide, tried at the Herts Lent Assizes, 1841 (see Guy's Hospital Reports, April'1842), the learned judge (Parke, B.) thus charged the grand jury: "With respect to all these cases (of infanticide), there is a degree of doubt whether the infant has been born alive. The law requires that this should be clearly proved, and that the whole body of the child should have come from the body of the parent. If it should appear that death was caused during delivery, then you will not find a true bill!" In the case (Reg. v. Christopher, Dorset Lent Assizes, 1845), Erle J. drew a distinction between medical (physiological) and legal life. The medical evidence clearly established that the child had expired. It was found with its head nearly severed from the body. Erle J. directed the jury that before they returned a verdict of guilty, they must be satisfied that the child was completely born, that is
had an existence distinct and independent from the mother, and that it was murdered by her. It was possible the child might have respired without being completely born into the world, and although this might medically be a live child, it was not one legally. In law, the birth of the child must be complete. The jury acquitted the prisoner. (Prov. Med. Jour., April 23, 1845.) In another case a medical witness was reprimanded for drawing the inference that the child was born alive, from the application of the hydrostatic test. This case was tried on the Midland Circuit in 1853, Reg. v. Stevens) before the late Baron Alderson. The body of the child was taken from a river: it was found in a pillow-case with a stone attached to it. There were several incisions on the throat, and the navel-string had been torn away. The state of the lungs showed that the child had breathed, and it was clearly proved to be the child of the prisoner. The medical witness is reported to have stated during his examination, that he had no doubt that the child was born alive; upon which the learned judge reproved him for his rashness, and inquired whether the appearances which he had observed enabled him to say more than that the child had breathed. The witness admitted they did not, and also that the child might have breathed before it was completely born. In his summing up, the learned judge remarked, that “the medical evidence only proved that the child had breathed; but a child may breathe before it is separated from the body of the mother, that is, before it is born, and this child may have died before it was born. We have therefore no certainty of there ever having been a person on whom murder could be committed.” The prisoner was acquitted.

From these decisions it will be seen that it is not sufficient for a medical witness to depose, from the state of the lungs, that the child was alive at or about the time of its birth; according to the present views of our judges, it is indispensably necessary for him to prove that the child was born alive, or that it was living after its body had entirely come into the world.

Conclusions.—The general conclusions respecting the employment of the hydrostatic test, to be drawn from the contents of this chapter, are—

1. That the artificial inflation of the lungs of a child born dead, will cause them to float in water.

2. That while lying in the chest, the fetal lungs are not easily inflated, and that the difficulty in inflating them is great in proportion as the child is immature.

3. That lungs artificially inflated in the chest, resemble those organs in which respiration has been only imperfectly established.

4. That in cases of inflation in the chest, hitherto tried, the air may be so far expelled from the divided portions of lung by firm compression, as to cause them to sink.
5. That the same result occurs with lungs in which respiration has been imperfectly established.

6. That when lungs have undergone perfect respiration, the air cannot be expelled by compression of the divided parts, so as to cause them to sink.

7. That the artificial inflation of fetal lungs causes no alteration of weight, and as the weight increases in proportion to the degree of respiration, so in healthy lungs, with great buoyancy, there should be great weight if the air have been derived from respiration.

8. That while respiration increases the absolute weight of the lungs, it diminishes their specific weight by leading to the distension of the pulmonary cells with air.

9. That when the lungs are very heavy, and contain but little air, it cannot with certainty be inferred, that respiration has been established. The facts, ceteris paribus, may be explained by supposing that the lungs have been artificially inflated.

10. That we should base our judgment of a child having breathed, upon great weight and great buoyancy of the lungs combined,—that the one condition without the other is open to the objection, that the air may not have been derived from respiration.

11. That experiments on fetal lungs, artificially inflated with air after removal from the chest, have no practical bearing on this inquiry.

12. That the floating of the lungs in water proves, ceteris paribus, that a child has breathed either at, during, or after birth; it does not prove that a child was born alive, or that it has died a violent death.

13. That the sinking of the lungs as a result of the expulsion of air from them by compression, does not necessarily prove that the child was born dead. It merely proves that the air contained in them was derived either from artificial inflation, or from the imperfect establishment of the respiratory process.

14. That the hydrostatic test is not applicable to determine the fact of respiration or non-respiration in all cases of alleged infanticide; but that with ordinary precautions, it may be safely employed in the majority of such cases.

15. That a child may breathe before, during, or after birth, but the hydrostatic test will not enable us to say, in the greater number of cases, at which of these periods the act of respiration was performed.

16. That respiration is a sign of life, and not necessarily of live birth.

17. That according to the present state of the law, the killing of a child which breathes during birth is not murder.

18. Hence medical evidence is required to show whether a child breathed after it was entirely born; and whether the act
EVIDENCE OF LIVE BIRTH FROM RESPIRATION.

of violence which caused its death was applied to it while so breathing.

These conclusions are here, for the sake of clearness, expressed with brevity. Some of them may appear to require qualification; but, for the circumstances which qualify them, the reader is referred to the contents of the chapter.

CHAPTER XLII.

The great question on a trial for child-murder is, whether the child has been born alive, and in order to answer this, it is necessary to consider what are the proofs of live birth which are available to the medical witness.

Evidence from respiration.—As a general rule there will be no perceptible difference in the state of the lungs, whether the act of respiration be performed by the child during parturition or after it is born, provided that its death speedily follows its birth. But should we find that this process has been perfectly established, i.e. that the lungs present all those conditions which have been described as characteristic of full and perfect respiration, there is great reason to presume, that the process, even if it commenced during birth, must have continued after the child was entirely born. This presumption becomes still stronger, when the child is immature; for, generally speaking, such children must be born and continue to expire for many hours after birth, in order that their lungs should present the characters of complete respiration. The process is seldom so established before birth as to give to these organs the feeling of crepitation under pressure; the existence of this character should, therefore, be sought for. A witness who relied upon it as a conclusive proof of respiration after birth, might be asked by counsel, whether it were not possible for some children to remain so long at the outlet with the head protruding, as to render the lungs crepitant from frequent respiration before entire birth. Admitting the bare possibility of this occurrence, he should endeavour to ascertain whether there
were any probable causes thus to protract delivery, while the head of the child was in this position; as also what natural cause could have produced its death when its head was protruding, and when respiration had been so freely performed as to give crepitation to the lungs. The presence or absence of the usual scalp-tumour might throw some light upon the case. If, when present, it did not prove live birth, it might indicate protracted delivery, and show that the child had been recently living.

Evidence from marks of violence.—If marks of violence apparently inflicted about the same time, be found on different and remote parts of the body, and these marks bear the characters of those produced during life, it is rendered probable that the whole of the body of the child was in the world, when they were caused. Marks of severe violence on one part, as the head or breech, would not always justify such a presumption, because it might be fairly objected that they had been unintentionally produced by the woman in her attempts at self-delivery, and yet the child not have been born alive. It would be for a witness to form an opinion from the circumstances accompanying the particular case, whether they had been thus occasioned. From this it will be seen, that, in making an examination after death, it is proper that every mark of injury on the body of a child should be noted down. In March 1848, I was consulted by Mr. Prince, a former pupil, in reference to a case in which the presumption of live birth rested mainly on the degree of respiration, and the position and nature of certain marks of violence found on the child’s body. The child, which was said to have been born dead, was exhumed two days after burial, and eleven days after birth, and the body examined by Mr. Prince. It was full-grown, and not putrefied; the skin pale, and free from lividity. There was a clean cut on the right arm, dividing the membrane (fascia) and muscles, as if made by a sharp instrument. The edges were much retracted, and the whole of the wound was of a florid red colour: but there was no swelling or other marks of inflammation. There was a large vesicle (like the vesication of a burn) on the scrotum, containing three drachms of yellow-coloured serum. On the right leg the muscles were exposed for nearly the whole length: the surface of the wound was of a deep scarlet colour, and the margin widely inflamed. It had the appearance as if fire had been applied to the leg, although there was no sign of charring. These facts tended to show that the child was living when the injuries were inflicted: while the nature and situation of the injuries rendered it impossible that they could have arisen from any accident during delivery. The state of the lungs was somewhat remarkable, —the left floated freely in water, and there was distinct crepitation in it: the right sank in water,—no portion of it when divided was observed to float. From the buoyant and crepitant state of the left lung, there was reason to presume that if respiration had
EVIDENCE FROM CERTAIN CHANGES IN THE BODY. 473

commenced during birth, it had continued afterwards. Mr. Prince therefore inferred that the child had been born alive:—this inference was corroborated by the appearance of the marks of violence. It is probable that the child did not live long after birth. The air could not have been derived from putrefaction or artificial inflation: therefore the only question here was, whether the child had breathed after its body was wholly in the world. The facts above mentioned justified the inference drawn by Mr. Prince. From a confession subsequently made by the female, it appeared that the child had been born alive, and had cried, but owing to the injuries inflicted on it, it did not survive birth longer than a quarter of an hour. Although it is a rare circumstance that one lung should become thus fully distended with air, while the other receives none, cases of this kind are on record. Chausser met with the left lung much more distended than the right in the bodies of children which had survived birth some hours. (Capuron, Méd. Lég. des Accouchemens, 411.) The general opinion is, that the right lung receives air more readily than the left, owing to the larger size and more direct course of the right bronchial tube.

Evidence from certain changes in the body.—In a child which has been born alive, or which has survived its birth, that portion of the umbilical cord which is contiguous to the abdomen undergoes certain changes: thus it becomes slowly shrivelled, and separates with or without cicatrization. The umbilical vessels are at the same time gradually closed. According to Billard, the obliteration of these vessels is effected in a peculiar way. The calibre diminishes as a result of the concentric enlargement of the coats, so that while the vessel retains its apparent size, its cavity is gradually blocked up. A quill would represent the form of the vessel in the fetal state, and a tobacco-pipe in the obliterated state. It is only by cutting through the vessel that the degree of obliteration can be determined.

The state of the umbilical cord has often furnished good evidence of live birth, when the other circumstances of the case were inadequate to furnish decisive proof. In the following case, for the particulars of which I am indebted to Mr. French, it might have been suspected, but for the state of the cord, that the child had been still-born, and that its lungs had been artificially inflated. The body of the child had been exhumed soon after burial, in consequence of some suspicion respecting the cause of death. It weighed nearly five pounds, and was eighteen inches long; the opening for the navel was exactly in the centre of the body. The hair on the scalp was about an inch in length, and plentiful; the nails reached to the extremities of the fingers and toes. There was no mark of violence about it. The navel-string had separated by the natural process, but the skin around was not quite healed. The tendon of one of the muscles of the leg
was prominent, and apparently contracted at the instep. The left testicle alone had descended into the scrotum,—the right was still in the inguinal canal. This rendered it probable that the child had not quite reached maturity. It was by this peculiarity of the instep that the body of the child was identified. In the first instance the body of another child had been brought from the same burial ground, but rejected, from the absence of this appearance of the foot. On opening the chest, the lungs were observed to be situated posteriorly, and not filling the cavity. They weighed together 361 grains—the right weighing 430, and the left 431 grains. The heart, thymus, and lungs were placed together in water, but they immediately sank to the bottom. The lungs when separated from the other organs, floated, but with a very slight degree of buoyancy. Indeed, this was established by the fact, that they sank with the heart and thymus attached. The lungs were cut into twenty-two pieces—three from the apex sank; the remaining nineteen pieces floated, and they were not made to sink by pressure. The foramen ovale was but slightly open and contracted, as well as the ductus arteriosus, to about one-half of the fetal diameter. The bladder was perfectly empty,—the intestines contained only mucus. The conclusions at the inquest were:—1. That the child had been born alive, and had lived certainly not less than three days, and probably longer.—2. That respiration during that time had been but imperfectly established.—3. That in all probability it had died a natural death. The conclusions were well warranted by the medical facts. Experiments on the lungs were here not absolutely necessary, owing to the state of the umbilical cord. It might have been objected to any inference from the condition of these organs, that the facts were explicable on the supposition of their having been artificially inflated. The case, therefore, furnishes another proof of the ease with which a speculative objection, on this ground, may be set aside. It was subsequently proved that the child had lived eight days after birth.

These changes in the umbilical cord, when found, clearly prove that a child has survived its birth, whatever may be the results of experiments on the lungs; but the difficulty is, that they require some days for their development, and in practice it is often necessary to procure some sign of survivorship of only a few minutes, or at farthest of a few hours. The same remark applies to the exfoliation of the cuticle in a new-born child: such a condition of the skin can very rarely be found in cases of infanticide. The absence of meconium from the intestines, and of urine from the bladder, are not proofs of live birth, for these may be discharged during birth, and yet the child not be born alive.

Evidence from changes in the heart and fetal vessels. Docimus in circulationis. — It has been supposed that the state of the
EVIDENCE FROM CHANGES IN THE FETAL VESSELS.

foramen ovale, ductus arteriosus, and canalis venosus, would aid a medical jurist in forming an opinion whether a child had survived its birth. In general, as a result of the establishment of respiration, it is found that the communication between the auricles of the heart by the foramen ovale becomes closed; and that the two vessels, after gradually contracting, become obliterated, or are converted into fibrous cords. Whatever may be the results of experiments on the lungs, it has therefore been contended, that the closure of the foramen and vessels would infallibly indicate that a child had breathed. This inference, however, has been too hastily drawn. Recent researches have shown, that there are some serious objections to any conclusions based on the state of the fetal vessels. The entire closure of these parts, as a natural process, always takes place slowly, and sometimes it is not complete until many years after birth. Thus, then, in the generality of cases of infanticide, in which necessarily the child survives but for a very short period, no evidence of the fact will be procurable by an examination of the heart and fetal vessels.

Ductus arteriosus.—Prof. Bernst, of Vienna, who has made many observations on this subject, has arrived at the following conclusions respecting the period required for the closure of the ductus arteriosus in children which have lived after birth:—1. If a child has lived only a few seconds, the aortal end of the duct appears contracted, and the vessel, instead of being cylindrical throughout, acquires the form of a truncated cone.—2. If a child has lived for several hours, or a whole day, the duct becomes again cylindrical, although shortened and contracted in diameter. Its size is about equal to a goose's quill; it is, therefore, much smaller than its root, and about as large as either of the two branches of the pulmonary artery, which have, in the meantime, become increased in size. —3. If a child has lived for several days or a whole week, the duct contracts to the diameter of a few lines,—about equal to a crow-quill, while the two branches of the pulmonary artery are equal in size to a goose's quill. —4. The duct is met with perfectly closed, and quite impervious, at a much later period; i.e. after the lapse of an uncertain number of weeks or even months. Among the exceptional conditions, Bernst remarks, that the contraction may be first observed at the cardiac instead of the aortal end. In one instance of a still-born child, which was resuscitated and breathed feebly for a short time, and in which the thymus gland was absent, the duct was found of the size of a crow-quill, as in children which have lived several days. He also states, on the authority of Joseph Schallgrüber, that the duct is sometimes entirely absent. (Das Verfahren bey der gerichtlich-medicinischen Ausmittelung zweifelhafter Todesarten der Neugeborenen, von Joseph Bernst, s. 67, Wien, 1826; also, Systematisches Handbuch der
gerichtlichen Arzneikunde, s 275, Vierte Auflage, Wien, 1834.)
— The conclusions of Professor Bernt are here given in order to
show that the natural closure of the duct is a very slow
process; but the conclusions are open to many more exceptions
than those admitted by the writer. Neither in his works, nor
in those of other authorities on medical jurisprudence, is any
case recorded which shows that the duct can become quite
imperious from natural causes in a child which has lived only a
few hours.

Although the closure may take place as a result of the es-
establishment of respiration, it is obvious that the time of its occur-
rence after birth is so uncertain as to render any evidence derived
from the non-closure altogether fallacious. I have examined the
bodies of several children which have survived birth for some
hours, and have not been able to discover any perceptible alter-
ation in the diameter of the duct either at its aortal or cardiac
end. In other cases partial contraction has been apparent. As
the closure depends on a diversion of blood through the lungs,
so it follows, that, when respiration is feeble or imperfect, the
duct will be found either of its natural patency, or, if closed, the
closure must be regarded as an abnormal deviation. In the case
of a child which died at the age of ten weeks, the ductus arte-
riosus was found to be freely open. (Med. Gaz. xl. 994.) The
researches of Dr. Norman Chevers have shown, that there are
numerous abnormal conditions which may give rise to non-
occlusion of the duct. (Med. Gaz. xxxvi. 190, and xxxviii. 961;
see also Orfila, Méd. Lég. 1848, ii. 212.) From the facts col-
lected by Dr. Chevers, it would appear that the duct is liable
to become contracted and even obliterated, before birth, and
before the child has breathed. In these cases there has been,
in general, some abnormal condition of the heart or its vessels;
but this, even if it exist, might be overlooked in a hasty ex-
amination; hence the contracted or closed condition of the duct
cannot be taken as an absolute proof that a child has been
born alive or survived its birth. In January 1847, Dr. Chevers
presented to the London Pathological Society, the case of a child
born between the seventh and eighth months, in which this vessel
was almost closed, being scarcely one-twelfth of an inch in di-
diameter, and capable of admitting only the shank of a large pin.
The tissues of the duct had altogether an appearance of having
undergone a gradual process of contraction; and its state proved
that its closure commenced previously to birth. In fact, the
child survived only fifteen minutes; while, according to Bernt's
rule, the medical inference might have been that this child had
lived a week. It is important to remark, that in this case the
heart and lungs were in their normal or natural state. (Med.
Gaz. xxxix. 205.)

The evidence derivable from the condition of the ductus arte-
riousus in a new-born child, was submitted to a rigorous examination in the case of Frith (Ayr Circ. Court of Justiciary, Oct. 1846). This important case was tried before the Lord Justice Clerk of Scotland, to whose kindness I am indebted for a full and accurate statement of the evidence. The body of the child was found in a bag which had been buried in the sands on the sea-shore at Ayr, a little above high-water mark, with such marks of violence about it, as left no doubt that it must have been deliberately and intentionally destroyed. Independently of severe injuries to the throat externally, the mouth and throat internally were found to be so closely stuffed with tow and other substances, that there was some difficulty in removing them. The body when found was much decomposed; the brain was pulpy, and the cuticle, as well as the bones of the skull, were easily separated. The weight of the body was seven pounds, and the child had the characters of maturity. The prisoner had, beyond doubt, been delivered of a child about three weeks previously to the discovery of this body. It was alleged that this was her child, and she was put on her trial for the murder.

The material question in the case was therefore one of identity. It depended on two sets of facts — ordinary and medical. The bag in which the body was found, was part of a cloth-covering of a cushion belonging to the mother and grandmother of the child. This being made out to the satisfaction of the jury, the evidence so connected the prisoner with the dead body, that the medical facts raised in the defence became only of secondary importance. On an inspection of the body the following appearances were met with. The heart and lungs weighed one ounce; the latter organs were collapsed. The right lung was considerably decomposed, and sank when placed on water: the left was of a red colour, firm in texture, and floated on the surface when immersed in a vessel filled with water; but on pressure there was no crepitation. The right side of the heart was filled with coagulated blood, the foramen ovale being partly open, and the ductus arteriosus impervious. The liver was large, and of a leaden hue, the ductus venosus almost obliterated, and meconium was found in abundance in the lower bowels. The reporters were of opinion, from the perfect conformation of the child’s body, and the above-mentioned appearances, that it had been born alive. The circumstantial evidence established that not more than five hours could have elapsed from the birth of the child to the time at which its body was buried in the spot where it was subsequently found; and that, admitting it to have been born alive, there was the strongest reason to believe that it did not survive its birth more than ten minutes. The results of experiments on the lungs were not alone sufficient to show that the child had been born alive. The organs were light, and not crepitan; the right lung was decomposed, and yet it sank in water,
while the left was firm, and floated. The defect in this part of the medical evidence was, however, (admitting the identity,) removed by the evidence of a man lodging in the prisoner's house, who deposed that he distinctly heard the child cry. He slept in the same room with the prisoner, on the morning on which she was delivered, and there does not appear to have been any reason to doubt his testimony.

Under these circumstances the defence taken up was, that, considering the state in which the ductus arteriosus was found, this could not have been the child of the prisoner, because, if destroyed after being born alive (which was disputed), it must clearly have been destroyed immediately after birth. In that case the ductus arteriosus could not have been found impervious; ergo, the body found was not the body of the prisoner's child. It was contended that, according to all previous experience, the duct could not be found impervious in a child which had ceased to live within a few minutes or even a few hours after birth. One medical witness for the prosecution admitted that it required some days or weeks for the duct to become impervious; but a case was reported by Beck in which it had closed within a day. Another stated that it is generally a considerable time before the duct becomes closed. Medical evidence was given in defence, to the effect that the earliest case of closure was twenty-four hours, and from the state of the duct in this case, the witness considered that the child must have survived for one day at least, or not much less. Another witness stated that the discovery of the closure in a body would lead him to infer that the child had survived three or four days. According to this evidence the body produced could not have been that of the prisoner's child. The jury, however, found that the child had been born alive, but that murder was not proven. (For reports of this case, see Med. Gaz. xxxviii. 897; and Ed. Monthly Journal, Nov. 1846, 385.)

It appears from the evidence given at the trial that circumstances quite irrespective of medical testimony, proved that this child had been born alive, that it was the child of the prisoner, and that it could have survived its birth only a few minutes. The medical evidence left it undoubted, that the child had been destroyed by violence. The facts that the mouth and throat were firmly packed with tow, and that there had been copious effusion of blood in the seats of violence, admit of no other explanation. To what, then, is the early closure of the duct in this case to be referred? So far as I am aware, there is no instance on record of the arterial duct becoming impervious within a period of five or six hours (in this case only as many minutes could have elapsed) after birth. Its closure is naturally the result of free and perfect respiration in a healthy child: but the state of the lungs in this instance showed that respiration had neither been full nor complete. It is probable, therefore, that
the case was similar to that described by Dr. Chevers, and that there was an abnormal condition of the duct. (See ante, page 476.) Either this must be assumed, or the closure must depend on other causes than perfect respiration: but experience shows, as a general rule, that it proceeds pari passu with this process.

Admitting that this abnormal state of the duct, i.e. its closure previous to birth, is in general accompanied by malformation of the heart, or great vessels connected with it, yet Dr. Chevers's case already related proves that this is by no means a necessary accompaniment. Hence, considering the serious responsibility attached to a medical opinion in a case of child-murder, the better rule will be to place no confidence on a contracted condition of this duct as evidence either of live birth or of the time during which the child has lived. It can only have any importance as evidence, when the death of a child speedily follows its birth; and these are precisely the cases in which a serious fallacy is likely to arise, for the contraction or closure may be really congenital, and yet pronounced normal. If a child has lived for a period of two or three days, (the time at which the duct naturally becomes contracted or closed,) then evidence of live birth from its condition may not be necessary: the fact of survivorship may be sufficiently apparent from other circumstances. Hence this species of evidence is liable to prove fallacious in the only instance in which it is required, and the case of Frith shows the dangerous uncertainty which must attend medical evidence based on the closed condition of the duct.

Canalis venosus.—There is not, so far as I know, any instance of the obliteration of this vessel previous to birth. When respiration is fully established, it collapses, and becomes slowly converted, in a very variable period of time, to a ligamentous cord or band, which is quite impervious. There is no doubt that in those cases in which it is stated to have become obliterated in children which could have survived birth only a few minutes or hours, the collapse of the coats has been mistaken for an obliteration of the canal. It is probably not until the second or third day after birth that its closure begins, although nothing certain is known respecting the period at which it is completed. The condition of this vessel, therefore, can throw no light upon those cases of live birth in which evidence of the fact is most urgently demanded.

Foramen ovale.—This valvular opening in the heart in general becomes closed after the establishment of respiration; but I have found it repeatedly open in children which had survived birth several hours; and, as it will be hereafter stated, the period of its closure is as variable as in the case of the ductus arteriosus. Hence it is not capable of supplying, with certainty, evidence of live birth, in those instances in which this evidence is required. According to Billard, the foramen becomes closed between the
second and third days; but there are numerous cases in which it is found not closed at much later periods after birth. Dr. Handyside states, that it is more or less open in one case out of eight. In 1838, two subjects were examined at Guy’s Hospital, one aged fifty, the other eleven years, and in both, the foramen was found open. There is, however, another serious fallacy, which has been only recently brought to light: the closure of the foramen ovale has been known to occur as an abnormal condition previously to birth and the performance of respiration. One case is mentioned by Capuron (Méd. Lég. des Accouchements, p. 337), and another, of an instructive kind, is reported in the Medical Gazette (vol. xxxviii. 1076). Other instances of this abnormal condition are adverted to by Dr. Chevers (Med. Gaz. xxxviii. 967); and it would appear, that in these the arterial duct remained open, in order to allow of the circulation of blood not only before, but subsequently to respiration. The children rarely survive birth longer than from twenty to thirty hours. Dr. Chevers justly observes, that “Cases of this description are of the highest importance in a medico-legal point of view, as they fully disprove the opinion maintained by many anatomists, that obliteration of the foramen ovale must be received as certain evidence that respiration has been established. It is assuredly impossible to deny that in the heart of a child which has died within the uterus, and has been expelled in a putrid condition, the foramen ovale may be found completely and permanently closed. In such cases as these, it would, however, probably be always possible to determine, by an examination of the heart and its appendages, that the closure of the foramen had occurred at some period or other antecedent to birth.” It would, therefore, be unsafe in practice to rely upon the closure of this aperture as a proof of live birth, in the absence of other good evidence: and in no case can its patency be regarded as a proof that a child has come into the world dead. Dr. Kidd met with the case of a newborn child, in which a thick layer of lymph had been deposited across the aperture so as nearly to block it up. The ductus arteriosus was completely closed. The child could not have survived its birth more than a few hours (Assoc. Jour., Feb. 4, 1853, p. 104). This deposit of lymph is a condition not usually found. Dr. Peacock considers that the foramen is closed by the contraction of a band of muscular fibres of which the valve is constituted. In a medico-legal point of view, the patency or closure of this aperture possesses no longer any importance (Assoc. Journal, Feb. 25, 1853, p. 177).

As a general rule, these peculiar parts of the fetal circulation are rarely obliterated by a normal process before the eighth or tenth day after birth. The obliteration, according to Bernt and Orila, takes place in the following order:—1. The umbilical arteries.—2. The canalis venosus.—3. The ductus arteriosus, and
4. The foramen ovale. (Orfila, Méd. Lég. 1848, ii. 210.) The circumstances connected with the closure of these fetal vessels have been statistically investigated by Dr. Elsässer. Among 70 still-born children they were found open in 69. Among 300 children who died soon after birth, 80 out of 108 prematurely born, and living from one to eight days, presented all the passages open;—127 out of 192 infants born at the full time had all the passages open but partly contracted. The ductus arteriosus was open in 55 cases and completely closed in 10 cases, the canalis venosus was open in 81 and completely closed in 37 cases: while the foramen ovale was open in 47 and completely closed in 18 cases. These facts, according to Dr. Elsässer, prove that the vessels peculiar to the fetal circulation remain open as a rule for some time after birth, and that it is not possible to determine accurately, by days, the period of their closure. This physiologist remarked that the closure commenced and was often completed in the canalis venosus, before it manifested itself in the other vessels. The complete closure, in by far the greater number of cases, takes place within the first six weeks after birth, and the instances of obliteration before birth or before the period mentioned after birth, must be regarded as rare exceptions. (Med. Times and Gaz. May 21, 1853, p. 590.)

The result of this inquiry respecting Professor Bernt's *docimasia circulationis* is essentially negative: it either proves nothing, or it may lead the medical witness into a fatal error. It has been the more necessary to point out the serious fallacies to which it is liable, because hitherto medical jurisprudence has been disposed to place great reliance upon it, in cases in which evidence from the state of the lungs was wanting. The necessity of these facts being known is shown by the case which occurred at Ayr (ante, p. 477), in which great reliance appears to have been placed upon the following statement by Dr. Beck:—"If, therefore, the ductus arteriosus be found cylindrical in its shape, and not contracted towards the aorta, and if it equal in size the trunk of the pulmonary artery, the inference would be that the child was not born alive. On the other hand, if the ductus arteriosus be contracted towards the aortal end, and if its size be much less than the trunk of the pulmonary artery, the inference would be, that the child had been born alive." (Beck's Med. Jur. 5th edit. p. 251.) From a consideration of the preceding facts, it will be seen that such inferences might seriously mislead a Court of Law.

Evidence from the state of the alimentary canal.—Good evidence of live birth may be sometimes derived from the discovery of certain liquids or solids in the stomach and intestines, such as blood, milk, or farinaceous or saccharine articles of food; for it is not likely that these substances would be introduced or swallowed during parturition, nor is it at all probable that they should
find their way into the stomach or intestines of a child which was really born dead.

Starch.—In the case of a new-born child, Dr. Geoghegan discovered, by the application of iodine water, the presence of farinaceous food in the stomach; hence the question of live birth was clearly settled in the affirmative. In a still more recent case, Dr. Francis, of Manchester, employed this mode of testing, with satisfactory results, even when the investigation was beset with unusual difficulties. He was required by the coroner to examine the body of a new-born child found under suspicious circumstances. The examination of the lungs left no doubt that respiration had taken place; and the fact that the child had been born alive, was fully established by the discovery in the stomach of a small quantity of farinaceous food. On digesting a fragment of the pulp found in this organ with distilled water, and adding a drop of a weak solution of iodine, an intense indigo-blue colour appeared immediately. The application of this chemical test, therefore, removed any doubts which might have been entertained on the question of live birth. (Med. Gaz. xxxvii. p. 460.)

Sugar.—In one case which I was required to examine, the presence of sugar was easily detected in the contents of the stomach by the application of Trommer’s test. In order to apply this test, a few drops of a very weak solution of sulphate of copper should be added to a portion of the concentrated aqueous extract of the contents of the stomach. An excess of a solution of caustic potash is then added, and the liquid boiled. If sugar be present, the sub-oxide of copper is immediately precipitated of a reddish-brown colour. With white sugar the same decomposition is effected, but more slowly. If starch be present, black oxide of copper may be thrown down, but there is no reduction. The production of the red oxide proves that some saccharine substance is present.

Milk.—This liquid, or its principle casein, forms a rich violet-blue solution with a few drops of a solution of sulphate of copper, and an excess of caustic potash. The red sub-oxide will be thrown down on boiling, if sufficient lactine (sugar of milk) be present. Casein, or the curd of milk, owing to its containing a trace of sugar, acts in a similar manner, but the decomposition takes place more slowly.

Albumen forms a deep violet-blue solution with potash and sulphate of copper, but the red sub-oxide is not precipitated on boiling. Either there is no effect, or if the caustic potash be in large quantity, the black oxide falls down. An instance is related by Dr. Döring in which a spoonful of coagulated blood was found in the stomach of a new-born child. The inner surface of the oesophagus and trachea was also covered with blood. Dr. Döring inferred from these facts, that the child had been born alive; for the blood, in his opinion, must have entered the stomach by swal-
lowing, after the birth of the child, and while it was probably lying with its face in a pool of blood. (See on this subject Henke's Zeitschrift, 1842, ii. 219.)

In forming a judgment in a doubtful case, a question may arise whether any and what substances naturally exist in the stomach of a fetus born dead. Dr. Robinson has drawn the following conclusions from his observations on the stomachs of two human fetuses, and on those of the calf, lamb, and rabbit:

1. That the stomach of the fetus, during the latter period of its uterine existence, invariably contains a peculiar substance, differing from the uterine liquid (liquor amnii), and generally of a nutritious (?) nature.

2. That in its physical and chemical properties, this substance varies very much in different animals, being in no two species precisely similar.

3. That in each fetal animal the contents of the stomach vary much at different periods; in the earlier stages of its development consisting chiefly of liquor amnii, to which the other peculiar matters are gradually added.

4. That the liquor amnii continues to be swallowed by the fetus up to the time of birth; and consequently after the formation of those matters, and their appearance in the stomach.

5. That the mixture of this more solid and nutritious substance with the liquor amnii constitutes the material submitted to the process of chymification in the fetal intestines. He considers the contents of the alimentary canal to be chiefly derived from the salivary secretion. It is his opinion that there is no gastric juice secreted until respiration is established. The medical jurist will perceive, therefore, that the discovery of farinaceous food, milk, or sugar in the stomach, will furnish evidence of birth; since substances of this kind are not found in the fetal stomach. The substances which naturally exist in the stomach of the fetus, are of an albuminous and mucous nature.

Defective evidence.—The slightest consideration will show that the signs of live birth above described are weak, and of purely accidental occurrence. If the child be destroyed during birth or within a few minutes afterwards, there will be no medical evidence to indicate the period at which its destruction took place. The external and internal appearances presented by the body, would be the same in the two cases. It is most probable that in the greater number of instances of child-murder, the child is actually destroyed during birth, or immediately afterwards; and therefore, the characters above described can rarely be available in practice. If any exception be made, it is with respect to the nature, situation, and extent of marks of violence; but the presence of these depends on mere accident. Hence, then, we come to the conclusion, that although medical evidence can often show, from the state of the lungs, that a child has really lived, it can very rarely be in a condition to prove in a case of infanticide, that its life certainly continued after its birth.
We could only venture upon this inference when the signs of respiration were full and complete, or food was found in the stomach. Why the destruction of a child should be treated in the one case as a venial offence, and in the other as a capital crime, is one of those anomalies in our criminal jurisprudence for which it is impossible to account. The inference which we may draw from these observations is, that if positive proof of entire live birth be in all cases rigorously demanded of medical witnesses on trials for child-murder, it is scarcely possible, when the prisoner is ably defended, that any conviction for the crime should take place. The only exception would be, where a confession was made by the accused, or the murder was actually perpetrated before eye-witnesses. The numerous acquittals that take place on trials for this crime, in face of the strongest medical evidence, bear out the correctness of this opinion. The child is proved to have lived and breathed, but the medical evidence fails to show that the living and breathing took place or continued after entire delivery. [For some judicious remarks on this defective state of the law, see Prov. Journ. April 2, 1851, p. 182.]

Conclusions.—The general conclusions which may be drawn from the facts contained in this chapter, on the question whether a child has or has not been born alive, are as follows:—

1. That if the lungs be fully and perfectly distended with air by the act of respiration, this affords a strong presumption that the child has been born alive, since respiration during birth is in general only partial and imperfect.

2. That the presence of marks of severe violence on various parts of the body, if possessing vital characters, renders it probable that the child was entirely born alive when the violence was inflicted.

3. That certain changes in the umbilical vessels, and the separation by a vital process and cica-trization of the umbilical cord, as well as a general peeling or scaling off of the cuticle, indicate live birth.

4. That the absence of meconium from the intestines, and of urine from the bladder, are not proofs that a child has been entirely born alive, since these liquids may be discharged during the act of birth.

5. That the open or contracted state of the foramen ovale or ductus arteriosus, furnishes no evidence of a child having been born alive. These parts may become closed and contracted before birth, and therefore in a child born dead; or they may remain open after birth in a child born living, even after the establishment of respiration.

6. That the presence of farinaceous or other food in the stomach proves that a child has been entirely born alive.

7. That irrespective of the above conclusions, there is no certain medical sign which indicates that a child, which has died at or about the time of birth, has been entirely born alive.
CHAPTER XLIII.

RULES FOR DETERMINING THE PERIOD OF SURVIVORSHIP IN CHILDREN THAT HAVE BEEN BORN ALIVE. APPEARANCES INDICATIVE OF A CHILD HAVING LIVED TWENTY-FOUR HOURS — FROM TWO TO THREE DAYS — FROM THREE TO FOUR DAYS — FROM FOUR TO SIX DAYS — FROM SIX TO TWELVE DAYS. UNCERTAINTY OF MEDICAL EVIDENCE. ON THE PERIOD WHICH HAS ELAPSED SINCE THE DEATH OF A CHILD. PROCESS OF PUTREFACTION IN THE BODIES OF NEW-BORN CHILDREN. GENERAL CONCLUSIONS.

If we suppose it to have been clearly established, that the child not only lived but was actually born alive, it may be a question whether it lived for a certain number of hours or days after it was born. The answer to this question may be necessary in order to connect the deceased child with the supposed mother. It has been remarked that scarcely any appreciable changes take place in the body of a living child, until after the lapse of twenty-four hours; and these changes may be considerably affected by its degree of maturity, healthiness, and vigour. The following may be taken as a summary of the appearances in a child which has survived its birth for different periods:

1. After twenty-four hours.—The skin is firm and pale, or less red than soon after birth. The umbilical cord is somewhat shrivelled, although it remains soft and bluish coloured, from the point where it is secured by a ligature, to its insertion in the skin of the abdomen. The meconium is discharged; but a green-coloured mucus is found on the surface of the large intestines. The lungs may be more or less distended with air, although in a case of survivorship for a period longer than this, no trace of air was found in them. With regard to the state of the lungs, it should be remembered, that when these organs are fully and perfectly distended, the inference is that the child has probably survived many hours; but the converse of this proposition is not always true. Several cases already reported show that when the lungs contain a very small quantity of air, it does not follow that the child must have died immediately after it was born.

2. From the second to the third day.—The skin has a yellowish tinge, the cuticle sometimes appears cracked, a change which precedes its separation in scales. (Devergie, l. 619.) The umbilical cord is brown and dry between the ligature and the abdomen.

3. From the third to the fourth day.—The skin is more yellow and there is an evident separation of the cuticle from the skin of the chest and abdomen. The umbilical cord is of a brownish-
red colour, flattened, semi-transparent, and twisted. The skin in contact with the dried portion presents a ring of vascularity or redness; — but Dr. Geoghegan met with this appearance in two cases of still-born children, and I have also seen it in four cases in which the children were born dead. (G. H. Rep. April 1842.) The colon is free from any traces of green mucus.

4. From the fourth to the sixth day. — The cuticle in various parts of the body is found separating in the form of minute scales or of a fine powder. The umbilical cord separates from the abdomen usually about the fifth day, but sometimes not until the eighth or the tenth. The membranous coverings become first detached, then the arteries, and afterwards the vein. If the umbilical aperture is cicatized and healed, it is probable that the child has lived from three weeks to a month after birth. The ductus arteriosus may be found contracted both in length and diameter; the foramen ovale may be also partly closed.

5. From the sixth to the twelfth day. — The cuticle will be found separating from the skin of the limbs. If the umbilical cord was small, cicatization will have taken place before the tenth day after birth. If large, a sero-purulent discharge will sometimes continue for twenty-five or thirty days. The ductus arteriosus is said to become entirely closed during this period; but this statement is open to exceptions which have been elsewhere pointed out (ante p. 481.). It need hardly be observed that the body rapidly increases in weight when the child has enjoyed active existence.

On the whole, it will be seen that the signs of survivorship for short periods after birth are not very distinct. There is commonly no difficulty in determining the fact after the second day. The changes stated to take place in the umbilical cord during the first twenty-four hours, may be observed in the dead as well as in the living child; and the other changes occur with much uncertainty as to the period. These, however, I believe the principal facts upon which a medical opinion on such a subject can be based; and it is in some respects fortunate, that great precision in assigning the time of survivorship is not demanded of medical witnesses.

Putrefaction in the new-born child. — A practitioner may be further required to state how long a period has elapsed since the death of the child. The answer to the previous question was derived from the changes which take place in the body of a child during life, while, in relation to the present inquiry, we must look to those which occur in the body after death: in other words, to the different stages of putrefaction. From the observations of Orfila, it would appear that the body of an infant putrefies more rapidly than that of an adult. (Traité des Exhumations.) In forming a judgment on this point, due allowance must be made for the influence of temperature, humidity, and the free access of
air. If the body has been sunk in water, putrefaction takes place more slowly than usual, and the process is slower in running than in stagnant water. When the body is floating on the surface of water, so as to be at the same time exposed to air, then putrefaction takes place very rapidly; —and this also happens when the body, after removal from water, has been exposed to the air for some time. Putrefaction is also retarded when the deceased child has been buried in the ground in a box or coffin, unless the process had already commenced prior to interment. When the body has been cut up and mangled before being thus disposed of, putrefaction takes place with much greater rapidity. (The Queen v. Railton, Stafford Winter Assizes, 1844.)

Conclusions.—The general conclusions respecting survivorship are:—

1. That the period for which a new-born child has survived birth, cannot be determined by any certain sign for the first twenty-four hours.

2. That after this period, an inference may be drawn from certain changes which take place progressively in the skin and umbilical cord externally, and in the viscera on inspection; —that these changes allow only of an approximate opinion within the first five or six days.

3. That the contraction of the foramen ovale and ductus arteriosus takes place from natural changes at such uncertain intervals, as to render it difficult to assign a period of survivorship from the state of these parts.

4. That the period which has elapsed since the child died, after it was born, can only be determined by observing the degree of putrefaction in the body compared with temperature, locality, and other conditions to which it has been exposed.

CHAPTER XLIV.

Causes of death in new-born children.—The next important question in a case of infanticide, and that upon which the charge of murder essentially rests, is,— what was the cause of death? 1. It is admitted that a child may die during birth or afterwards.

2. In either of these cases it may die from natural or violent
causes. The violent causes may have originated in accident or cin
criminal design. The last case only, involves the corpus delicti of 
child-murder. If death has clearly proceeded from natural
causes, it is of no importance to settle whether the cause operated
during or after birth: — all charge of criminality is thenceforth
at an end.

Proportion of children born dead.—It is well known that of
children which are born under usual circumstances, a great num-
ber die from natural causes either during birth or soon after-
wards: and in every case of infanticide, death will be presumed
to have arisen from some cause of this kind, until the contrary
appears from the evidence. This throws the onus of proof en-
tirely on the prosecution. Many children die before performing
the act of respiration; and thus a large number come into the
world still born or dead. The proportion of still-born among
legitimate children, as it is derived from statistical tables exten-
sing over a series of years and embracing not less than eight
millions of births, varies from one in eighteen to one in twenty of
all births. (B. and E. Med. Rev. No. vii. 235.) Dr. Lever found,
that among three thousand births, one child in eighteen was born
dead. In immature and illegitimate children, the proportionate
mortality is much greater, — probably about one in eight or ten.
In Göttingen the deaths were found to amount to one in seven,
and in Berlin, to one in ten. (Ed. Med. and Sur. Jour. xxxvi. 172.)
Males are more frequently born dead than females, in the ratio
of 140:100, — while the males to females born has only a ratio of
The preponderance of still-births among males is ascribed to the
large size of the head, and the injury thus likely to be inflicted on
the brain during parturition. Still-births are much more fre-
cquent in first than in after pregnancies. These facts should be
borne in mind, when we are estimating the probability of the
cause of death being natural. Should respiration be established
by the protrusion of the child’s head from the outlet, or the
birth of its body, the chances of death from natural causes are
considerably diminished. Nevertheless, as Dr. Hunter long ago
suggested, a child may breathe and die. Thus, according to
this author, — “If the child makes but one gasp and instantly
dies, the lungs will swim in water, as readily as if it had breathed
longer and had then been strangled.” In general, it would re-
quire more than one gasp to cause the lungs to swim readily in
water; but waving this point, the real question is, — if the child
breathed after birth, what could have caused its death? The
number of gasps which a child may make, or which may be
required for the lungs to swim in water, is of no moment: — the
point to be considered is, whether its death was due to causes of an
accidental or criminal nature. So again observes Dr. Hunter;
“ We frequently see children born, who from circumstances in
their constitution or in the nature of the labour, are but barely alive, and after breathing a minute or two or an hour or two, die in spite of all our attention. And why may not this misfortune happen to a woman who is brought to bed by herself?” (Op. cit.) The substance of this remark is, that many children may die naturally after birth; and in Dr. Hunter’s time, these cases were not perhaps sufficiently attended to. In the present day, however, the case is different:—a charge of child-murder is seldom raised except in those instances where there are the most obvious marks of severe and mortal injuries on the body of a child; and unless it be intended to defend and justify the practice of infanticide, it must be admitted that the discovery of violence of this kind on the body of a new-born infant, renders a full inquiry into the circumstances necessary. Among the natural causes of the death of a child, may be enumerated the following:—

1. Protracted delivery — The death of a child may proceed, in this case, from injury suffered by the head during the violent contractions of the uterus, or from an interruption to the circulation in the umbilical cord before respiration is established. A child, especially if feeble and delicate, may die from exhaustion under these circumstances. This cause of death may be suspected when a sero-sanguinous tumour (called cephalae-matoma, or caput succedaneum) is found on the head of a child, and the head itself is deformed or elongated:—internally by the congested state of the cerebral vessels. The existence of deformity in the pelvis of the woman might corroborate this view; but in primiparous females (among whom charges of child-murder chiefly lie), with well-formed pelves, delivery is frequently protracted. It is presumed that there are no marks of violence on the body of the child, excepting those which may have arisen accidentally in attempts at self-delivery.

2. Debility. — A child may be born prematurely or at the full period, and not survive its birth owing to a natural feebleness of system. This is especially observed with immature children; and it is the condition more especially dwelt on by Dr. Hunter. Such children may continue in existence for several hours, feebly respiring, and then die from mere weakness. These cases may be recognised by the appearance of a general want of development in the body.

3. Haemorrhage. Laceration of the cord.—A child may die from loss of blood, owing to a premature separation of the placenta or an accidental rupture of the umbilical cord. In the latter case it is said the loss of blood is not likely to prove fatal, if respiration has been established; but an instance is reported in which a child died from haemorrhage even under these circumstances. (Henke’s Zeitschrift, 1839, Erg. H. 200; also 1840, i. 347, and ii. 105. Ann. d’Hyg. 1831, ii. 128.) Bleeding from the cord has in some cases taken place at various
periods after birth, and has led to the death of the child. (Ed. Month. Jour. July 1847, 70.) Death from haemorrhage may be commonly recognised by the blanched appearance of the body and a want of blood in the internal organs, but there are several cases on record in which the cord was ruptured close to the abdomen without causing the death of the child. It was formerly a debated question whether in the event of the umbilical cord being left untied after cutting or laceration, such a degree of haemorrhage could in any instance occur as would prove fatal to a child. The case just now referred to, renders it unnecessary to discuss this question. Bleeding is more likely to prove fatal when the cord is divided by a sharp instrument, than when it is lacerated; and its dangerous effects on a child are likely to be great in proportion as the division is made near to the umbilicus. It has been improperly described as a case of infanticide by omission, when a self-delivered woman neglects to apply a ligature to the cord under these circumstances; because it is said she ought to know the necessity for this in order to prevent the child dying from haemorrhage. Such a view assumes not only malice against the accused, but that in the midst of her distress and pain she must necessarily possess the knowledge and bodily capacity of an accoucheur,—a doctrine wholly repugnant to the common feelings of humanity. This question was, however, actually raised in the case of the Queen v. Dash, August 1842. There was no doubt in this instance that the child had breathed, and that its death had been caused by bleeding from the lacerated umbilical cord. The medical witness properly admitted, that the cord might have been torn through by the mere weight of the child during labour; and the jury acquitted the prisoner on the ground that she might have been ignorant of the necessity or not have had the power to tie the cord. The cord, especially when short, may become accidentally ruptured during delivery. A case of this kind occurred to Mr. Mackie. (Med. Times, July 24, 1847, p. 433.) The child was born alive, after a very strong pain, and on examination it was found that the cord was torn through at about an inch from the abdomen.

Bleeding from the vessels of the cord may prove fatal several days after birth, even when the child has been properly attended to, and the navel-string has separated by the natural process. Mr. Willing has recently reported a case of this kind, in which, in spite of every application, the child died from loss of blood six days after the separation of the cord. (Med. Times and Gaz. March 25, 1854, p. 287.) The impossibility of arresting the bleeding in this case, appeared to depend upon a great deficiency of fibrin in the blood, and a consequent want of tendency to coagulation.

4. Compression of the cord. — When a child is born by the feet or buttocks, the cord may be so compressed under strong uterine
contraction, that the circulation between the mother and child will be arrested, and the latter will die. The same fatal compression may follow, when during delivery the cord becomes twisted round the neck. A child has been known to die under these circumstances before parturition, the cord having become twisted round its neck in utero. (Med. Gaz. Oct. 1840, 122.) Other cases from this cause, during delivery, will be found in the same journal. (Vol. xix. 232, 933.) On these occasions, the child is sometimes described to have died from strangulation; but it is evident that before the establishment of respiration, such a form of expression is improper. There are few or no appearances indicative of the cause of death. There may be lividity about the head and face, and cerebral congestion internally: it is, however, proper to state, that the brain of a child is always more congested than that of an adult.

5. Malformation.—There may be a deficiency of some vital organ, which would at once account for the child dying either during delivery or soon after its birth. Two cases are reported, in one of which the child died from an absolute deficiency of the oesophagus,—the pharynx terminating in a cul-de-sac: in the other, the duodenum was obliterated for more than an inch, and this had occasioned the child's death. (Med. Gaz. xxvi. 542.) In a third, recorded by Mr. Fairbairn, a child was suffocated by retraction of the base of the tongue owing to defect of the fraenum. (North. Jour. Med. March 1846, p. 278.) The varieties of malformation are very numerous, but there can be no difficulty in determining whether it be such as to account for death. Individuals are not allowed to destroy these monstrous births; and the presence of all marks of violence in such cases should be regarded with suspicion. It is the more necessary to make this statement, as there is an idea among the vulgar, that it is not illegal to destroy a monstrous birth. Mr. Pooley, of Cirencester, has communicated to me a case which occurred some years since in his practice:—A lady was delivered of a most hideous dicephalous monster. In his absence, and at the earnest solicitations of the friends, the nurse destroyed it. The question was—Was this woman guilty of child-murder? The only case in reference to this point which is recorded by medico-legal writers, is that of two women who were tried at the York Assizes in 1812, for drowning a child which was born with some malformation of the head, in consequence of which it was likely that it could not survive many hours. There did not appear to have been any concealment on the part of the prisoners, who were not aware of the illegality of the act. (Paris and Foublanche, Med. Jr. l. 228.) The absence of malicious intention would probably lead to an acquittal on a charge of murder; but such an act would doubtless amount to manslaughter. The degree of monstrosity or the viability of the offspring cannot be received as extenuating.
circumstances: as to the first, if a liberty of judging what was monstrous and what not, were conceded to any ignorant nurse, children simply deformed might be put to death on that pretense:—as to the second, it is held in law that whoever accelerates death causes it,—hence the fact that the offspring is not likely to live more than a few hours, does not justify the act of one who prematurely destroys it.

6. **Congenital disease.**—It has been elsewhere stated, that a child may be born labouring under such a degree of congenital disease as to render it incapable of living. The discovery of any of the fetal organs merely in a morbid condition, amounts to nothing, unless the disease has advanced to a degree which would be sufficient to account for death. There are doubtless, many obscure affections, particularly of the brain, which are liable to destroy the life of a child without leaving any well-marked changes in the body. According to Dr. Burgess, apoplexy and asphyxia are very common causes of death among newborn children. (Med. Gaz. xxvi. 492; Henke’s Zeitschrift der S. A. 1843, p. 67.) Probably diseases of the lungs are of the greatest importance in a medico-legal view; because, by directly affecting the organs of respiration, they render it impossible for a child to live or to survive its birth for a long period. These diseases in the fetal state are principally congestion, hepatisation, tubercles, seirhus, and oedema,—the existence of any of which, it is not difficult to discover. They render the structure of the lungs heavier than water; and thus prevent the organs from acquiring that buoyancy which in their healthy state they are known to possess. It is not common to find the lungs diseased throughout:—a portion may be sufficiently healthy to allow of a partial performance of respiration. The lungs may not be found diseased, but simply in that state which has been elsewhere described under the name of atelectasis (auto, p. 448). The causes upon which this condition of the lungs depends, are not well understood. The non-establishment of respiration sometimes arises from the mouth and fauces of the child being filled with mucus. An enlargement of the thyroid gland has occasionally led to the death of a new-born child by suffocation. (Ed. Month. Jour. July 1847, 64.)

**Conclusions.**—The following conclusions may be drawn from the preceding remarks:

1. That a large number of illegitimate children, especially when immature, are born dead from natural causes.
2. That a child may die from exhaustion, as the result of a protracted labour.
3. That if a child be prematurely born, or if it be small and weak even at the natural period, it may die from mere debility or want of power in the constitution to commence or continue the act of respiration.
4. A child may die from haemorrhage, owing to accidental rupture of the cord during delivery. It may even die from this cause after it has breathed.

5. That fatal bleeding is more likely to occur when the cord has been cut close to the abdomen, than when it has been lacerated or cut at a distance from the navel.

6. That the division of the cord, whether by rupture or incision, without ligature, is by no means necessarily fatal to a healthy mature child.

7. That a child may die from accidental compression of the cord during delivery,—the circulation between the mother and child being thereby arrested before respiration has commenced.

8. That death may speedily follow birth, from some malformation or defect of important organs.

9. That a child may die from congenital disease affecting the organs of respiration or the air-passages.

CHAPTER XLV.

Violent causes of death.—In this chapter we shall have to consider all those modes of death which are totally independent of the existence of congenital disease or other natural causes. It is proper for the medical jurist to remember that there are certain forms of child-murder which are not necessarily attended with any appearance indicative of violence,—these are, suffocation, drowning, exposure to cold and starvation.

1. Suffocation.—This is a very common cause of death in new-born children. A wet cloth may be placed over the child's mouth, or thrust into that cavity during birth or afterwards, and before or after the performance of respiration. To the latter case only, could the term suffocation be strictly applied. A child may be thus destroyed by being allowed to remain closely
compressed under the bed-clothes after delivery, or by its head being thrust into straw, feathers, and such-like substances. The appearances in the body are seldom sufficient to excite a suspicion of the cause of death unless undue violence has been employed. There is commonly merely lividity about the head and face, with slight congestion in the lungs. A careful examination of the mouth and fauces should be made, as foreign substances are sometimes found in this situation, affording circumstantial evidence of the mode in which the suffocation has taken place. Thus wood, straw, feathers, dust, tow, or a hard plug of linen, may be, and in some cases have been, found blocking up the mouth and fauces (ante, p. 477). Again, a child may be suffocated by having its head held over noxious vapours, as the exhalations of a privy or of burning sulphur; and it may be here necessary to remind the medical jurist that other highly poisonous vapours may be used by a criminal without leaving any trace upon the body, except, possibly, that which may depend upon their peculiar odour. There are few of these cases of suffocation in which a medical opinion of the cause of death could be given, unless some circumstantial evidence were produced, and the witness were allowed to say whether the alleged facts were sufficient to account for death. (Annales d’Hyg. 1832, i. 621.)

On the other hand, if it be even clearly proved that death has been caused by suffocation, it must be remembered that a child may be accidentally suffocated, and the crime of murder falsely imputed. Dr. Hunter, who was well aware of the risk to which a female might be thus exposed, observes in relation to this point,—"When a woman is delivered by herself, a strong child may be born perfectly alive, and die in a very few minutes for want of breath, either by being on its face in a pool formed by the natural discharges or upon wet clothes;—or by the wet things over it collapsing and excluding air, or drawn close to its mouth and nose by the suction of breathing. An unhappy woman delivered by herself, distracted in her mind and exhausted in her body, will not have strength or recollection enough to fly instantly to the relief of her child." (Op. cit. 35.) It may be added that a primiparous female may faint or become wholly unconscious of her situation; or if conscious, she may be ignorant of the necessity of removing the child, and thus it may be suffocated without her having been intentionally accessory to its death. In such cases, however, there should be no marks of violence on the body, or if present they should be of such a nature and in such a situation as to be readily explicable on the supposition of an accidental origin. An infant is very easily destroyed by suffocation. If the mouth and nostrils be kept covered for a very few minutes, by being closely wrapped in clothes, asphyxia may come on without this being indicated by convulsions or any other marked symptoms. A suspicion of murder may arise in
ALLEGED ACCIDENTAL SUFFOCATION.

such cases; but the absence of marks of violence, with an explanation of the circumstances, will rarely allow the case to be carried beyond an inquest. Sometimes the body is found maltreated, with severe fractures or contusions on the skull, with marks of strangulation on the neck,—concealed in a feather-bed or privy:—or cut up and burnt. This kind of violence may properly excite a suspicion of murder, and lead to the belief that the allegation of death from accidental suffocation is a mere pretence. This, however, is purely a question for the jury, and not for a medical witness. Unless the case be of a very glaring nature, the violence is considered to have been employed for the purpose rather of concealing the birth of a child than of destroying it. In the present day, these cases of death from accidental suffocation, when properly investigated, can never implicate an innocent woman in a charge of murder, although the facts may show in many instances that the death of the child was really due to great imprudence, neglect, or indifference.

The following case, (the Queen v. Mortiboys,) tried in 1841, will show that even when the evidence is very strong against a person, the circumstances will be favourably interpreted. In this instance, it was proved that the body of the child was discovered in a box containing wool: it was lying on its abdomen, with its face raised and its mouth open. A red worsted comforter had been passed twice round the neck, and was tied a second time in a single knot over the chin. In the mouth, which was open, was found a small quantity of fine flocks of wool. The medical evidence showed that the child had been born alive, the left lung being fully inflated. The brain was congested. There was no mark produced by the ligature on the neck, either externally or internally. Death was referred to obstructed respiration (suffocation), caused partly by the ligature and partly by the wool in the mouth,—but the latter was considered to be the more active cause. In the defence it was urged that the ligature could not have produced strangulation, because the comforter was tied upon the chin,—that the medical evidence showed the wool in the mouth to have been the immediate cause of death,—this was probably taken into the mouth by the child itself in the instinctive action of breathing, and not put there by the prisoner for the purpose of suffocation. The child had probably been placed carelessly on a quantity of wool, into which it had sunk by its own weight, and this had caused its death. It is reported that the judge joined in this view, and in charging the jury, said, that had the prisoner intended to choke the child with the wool, she would have inserted enough to fill its mouth. The prisoner was acquitted. In this case, admitting that the evidence did not bear out the charge of murder, still it is pretty clear that death was caused by the child being placed on its face, with a ligature.
round the neck, in a close box filled with wool. Admitting the facts to have been as represented, there appears to have been in this case something more than an accident: for the prisoner must have known that a new-born infant was not likely to live long under such circumstances, and had the child been a week or a month old she would probably have been convicted of manslaughter or murder. A case of alleged infanticide, by suffocation, has been reported by Dr. Easton. (Cormack's Journal, Feb. 1845.) There is no doubt that the child in this case was suffocated by a quantity of mud being forced into its mouth and nose. Its presence in the esophagus was incommensurate with its having entered by gravitation. In the case of Mackintosh (Glasgow Ant. Circ. 1829), several small pieces of straw were found in the stomach of the child, of the same kind as those which were in the bed where the birth took place.

2. Drowning.—The fact of drowning cannot be verified by any appearances on the body of a child which has not breathed. Thus, if a woman caused herself to be delivered in a bath, and the child were forcibly retained under water (a case which is said to have occurred), it would of course die; but no evidence of the mode of death would be found in the body. [For a case in which a child was thus destroyed, probably however through accidental circumstances, see Cormack's Ed. Journal, Oct. 1843, p. 796.] After respiration, the signs of drowning will be the same as those met with in the adult. (See post. Drowning.) The main question for a witness to decide, will be whether the child was put into the water living or dead. Infanticide by drowning is by no means common;—the child is generally suffocated, strangled, or destroyed in other ways, and its body is then thrown into water, in order to conceal the real manner of its death. The fact of the dead body of an infant being found in water, must not allow the witness to be thrown off his guard, although a verdict of "found drowned" is so commonly returned in these cases. The body should be carefully inspected, in order to determine what was really the cause of death. All marks of violence on the bodies of children that have died by drowning, should be such as to have resulted from accidental causes. It is not necessary that the whole of the body should be submerged, in order that a child should be destroyed by drowning: the mere immersion of the head in water will suffice to produce all the usual effects. The ear passages should therefore be examined for foreign substances. A case occurred in London, in 1842, in which a woman attempted to destroy her child by immersing its head only, in a bucket of water. The child was discovered, and resuscitated.

New-born children may be drowned or suffocated by being thrown into mud, or into the soil of a privy. Sometimes the child is destroyed by other means, and its body is thus disposed of for the purposes of concealment. Should there be a large quantity of
liquid present, the phenomena are those of drowning. This liquid abounding in hydrosulphuret of ammonia may then be found, if the child were thrown in living, in the air-passages and the stomach. On these occasions, the defence may be—1, that the child was born dead, and that the body was thrown in for concealment; but the medical evidence may show that the child had breathed and had probably been born living. 2. It may be alleged that the child breathed for a few moments after birth, but then died, and that the female thus attempted to conceal the body. A medical witness may be here asked, whether a woman could have had power to convey the body to the place,—a point which must, as a general rule, be conceded. 3. It is most commonly urged, that the woman being compelled to go to the privy, was there delivered unconsciously, and that the child dropped from her, and was either suffocated or prevented from breathing. All these circumstances may readily occur, but on the other hand the explanation may be inconsistent with medical facts. Thus the head or the limbs of a child may be found to have been separated or divided by some cutting instrument,—or a cord or other ligature may be found tightly bound around its neck, or there may be a tightly fitting plug in the fauces. Then, again, the body may be entire, but the umbilical cord may be cleanly cut. This would tend to set aside the explanation of the child having accidentally dropped from the female; because in such an accident the cord should be found ruptured. The practitioner should make a careful examination of the divided ends of the cord by the aid of a lens, or a rupture may be mistaken for a section with a sharp instrument. Mr. Higginson, of Liverpool, has lately published a case of some interest in this point of view. The child fell from the mother, and the cord broke spontaneously. "The torn ends were nearly as sharp-edged and flat as if cut." (Med. Gaz. vol. xlvi. p. 985.) This case goes to prove that a careless or hasty examination of the ends of the cord may lead to a very serious mistake. Sometimes the mark of a previous cut may be found on the cord near one of its divided ends,—the first cut with scissors not having effectually divided it. In a case tried at Lewes Lent Assizes, 1852, Mr. Gardner proved, in reference to the body of a child which had been found in a privy, that the cord had been ineffectually cut in one spot previous to its complete division. The cord had also been pulled out after this cut, so as to elongate the vessels; hence they projected from one part of the sheath at one cut portion, while they were retracted in the other. This accurate observation showed not only that the cord had not been ruptured by the child accidentally falling from the mother, but it served to establish the identity of the placenta, which was found concealed at a distance from the body. When the cord is lacerated, this will be, ceteris paribus, in favours of the woman’s statement as to the mode in which her delivery
DEATH DURING SUDDEN DELIVERY.

occurred. (For a case involving this question, see Med. Gax. x. 374.) In a case which occurred to Dr. Wharrie, in which the child fell from a female while sitting over a large jug containing water, and in which it was evident there had been no respiration, the cord was found tied. The child was removed from the vessel dead; therefore, the ligature must have been applied after death. Drowning may be the result of accident from sudden delivery. A woman in an advanced stage of pregnancy while sitting on a chamber vessel was suddenly delivered. The child fell into the fluids in the vessel, and before assistance could be rendered it was dead.

Circumstantial evidence. — Whether, in any instance, the drowning of a child was accidental or criminal, must be a question for a jury to determine from all the facts laid before them. The situation in which the body of an infant is found, may plainly contradict the supposition of accident. On the other hand, a child may be accidentally drowned by its mouth falling into a pool of the discharges during delivery, although this would be rather a case of suffocation. The stomach of the child should always be examined on these occasions, as mud, sticks, straws, weeds, or other substances, may be found, indicating, according to circumstances, that the child had been put into the water living, and that it had been drowned in a particular pond or vessel.

Sudden delivery. The pains of labour mistaken for other sensations. — In cases like that reported by Dr. Wharrie, where a female, under the impression that she was about to have a motion, sat over a large water-jug and was delivered of a child, it is proper to make full allowance for a mistake which may be compatible with innocence. A woman is often unable to distinguish the sense of fulness, produced by the descent of the child, from the feeling which leads her to suppose that she is about to have an evacuation; and thus it is dangerous, when a labour has advanced, to allow a female to yield to this feeling; for there is nothing more probable than that the child will be suddenly born. Mr. Raukin, of Carlisle, has reported two cases of this description, where there could not be the slightest suspicion of criminality. In one, a primipara, the child was actually born under these circumstances; but its life was fortunately saved,—had there been no other convenience than a privy, it must have been inevitably lost. In the second, although a case of third pregnancy, the female was equally deceived by her sensations. (Ed. Month. Jour. Jan. 1846, p. 11.) It is true that this alleged mistaken sensation forms a very frequent and specious defence on charges of child-murder; but still a medical jurist is bound to admit that an accident which occurs to females of the middle class, may also occur to the poor without necessarily implying guilt.

Power of exertion in recently-delivered females. — On these occa-
sions, a witness will often find himself questioned respecting the strength or capability for exertion evinced by the lower class of women, shortly after child-birth. Alison remarks, that many respectable medical practitioners, judging only from what they have observed among the higher ranks, are liable to be led into an erroneous opinion, which may be injurious to an accused party. He mentions a case, in which a woman charged with child-murder walked a distance of twenty-eight miles in a single day, with her child on her back, two or three days after her delivery. (Case of Anderson, Aberdeen Spring Circ. 1829.) Instances have even occurred in which women have walked six and eight miles on the very day of their delivery, without sensible inconvenience. (Criminal Law, 161.) In one case (Smith, Ayr. Spr. Circ. 1824), the woman was engaged in reaping,—retired to a little distance, effected her delivery by herself, and went on with her work for the remainder of the day, appearing only a little paler and thinner! In the case of Maedongal (Aberdeen Spring Circ. 1823), the prisoner, who was sleeping in bed with two servants, rose, was delivered, and returned to bed without either of them being conscious of what had occurred. Cases like the last have often presented themselves in the English Courts.

3. Cold.—A new-born child may be easily destroyed by simply exposing it uncovered, or but slightly covered, in a cold atmosphere. In a case of this kind, there may be no marks of violence on the body, or these may be slight and evidently of accidental origin. In death from cold, the only appearance occasionally met with has been congestion of the brain with or without serous effusion in the ventricles. (See Cold.) The evidence, in these cases, must be purely circumstantial. The medical witness may have to consider, how far the situation in which the body was found,—the kind of exposure and the temperature of the air, would suffice to account for death from the alleged cause. There is no doubt that a new-born child is easily affected by a low temperature, and that warm clothing is required for the preservation of its life. An inspection of the body should never be omitted on these occasions; because it might turn out that there was some latent cause of natural death which would at once do away with the charge of murder. Admitting that the child died from cold, it becomes necessary to enquire whether the prisoner exposed it with the malicious intention that it should thus perish. Unless wilful malice be made out, the accused cannot be convicted of infanticide. In general, females do not expose their children for the purpose of destroying them, but for the purpose of abandoning them; hence it is rare to hear of convictions for child-murder, where cold was the cause of death, although some medical jurists have called this infanticide by omission, an offence which does not appear to be
recognised by the English law. In the case of the Queen v. Walters (Oxford Autumn Assizes, 1841) it was proved that the prisoner, while travelling in a waggon, had suddenly left it, and that she was delivered of a child, which was afterwards found dead and exposed on the road. There was no doubt that the child had been born alive; for it was heard to cry after it was abandoned by its mother, who appeared to have carried it some distance after it was born. The child had died from exposure to cold. The woman was convicted of manslaughter, and sentenced to ten years' transportation. (For other medico-legal cases of death from cold, see Henke's Zeitschrift, 1836; also, 1840, i. 168, Erg. H.) In the case of Reg. v. Waters (Exchequer Chamber, Jan. 1849), the judges held on appeal that the count which charged the prisoner with causing the death of her child by throwing it on a dust-heap, and leaving it exposed, was good, and the conviction was affirmed.

4. Starvation.—A new-born child kept long without food will die, and no evidence of the fact may be derivable from an examination of the body. There may be no marks of violence externally, nor any pathological changes internally, to account for death. This is a rare form of committing murder, unless it may be accidentally combined with exposure to cold. In order to convict the mother, it is necessary to show that the child was wilfully kept without food, with the criminal design of destroying it. Mere neglect or imprudence will not make the case infanticide. The only appearance likely to be found on examination of the body, would be complete emptiness of the alimentary canal. Without corroborative circumstantial evidence, this would not suffice to establish the cause of death: a medical witness could only form a probable conjecture on the point. In a suspected case of this kind, the contents of the stomach should be tested for farinaceous and other kinds of food. (See Starvation, post.)

5. Immaturity in cases of abortion.—From the case of Reg. v. West, Nottingham Lent Assizes, 1848, it would appear that if by the perpetration of abortion, or the criminal inducement of premature labour, a child be born at so early a period of uterine life that it dies merely from immaturity, the party causing the abortion, or leading to the premature birth, may be tried on a charge of murder. A midwife was alleged to have perpetrated abortion on a female who was between the fifth and sixth month of pregnancy. The child was born living, but died five hours after its birth. There was no violence offered to it; and its death appeared to be due entirely to its immaturity. The prisoner was acquitted, apparently on the ground that abortion might have arisen from other causes.

Among those cases of violent death which leave on the body of the child certain marks or appearances indicative of the cause, may be mentioned wounds, strangulation and poisoning.
6. Wounds.—Probably this is one of the most frequent causes of death in cases of infanticide. Wounds may, however, be found on the body of a child, which has died from some other cause. The principal questions which a medical witness has to answer, are:—1. Whether the wounds were inflicted during or after birth, or, to adopt the legal view of the matter, before or after the body of the child was entirely in the world, in a living state: for according to the decisions of our judges, a child is not considered living in law, at least its destruction does not appear to be murder, until its body is entirely born. In most cases it will be utterly impossible for a medical witness to return any answer to a question put in this form. All that medical evidence can pretend to show, is whether a child was living or not when the wounds were produced:—for whether the whole of its body was or was not in the world at this time, they will possess precisely the same characters. In a few cases only, a conjectural opinion may be formed from the nature, extent, and situation of these injuries.—2. The witness will be required to state, whether the wounds were inflicted before or after death.—3. Whether they were sufficient to account for death.—4. Whether they originated in accident or criminal design. The child may have been destroyed by burning, and evidence must then be sought for by an examination of the state of the skin. All these questions have been fully considered in treating the subject of Wounds; and they therefore do not require any further notice in this place.

A case of infanticide was tried at the Buckingham Summer Assizes, 1840 (the Queen v. Wood), in which the main question was, whether five severe wounds found on the head of a child were inflicted before or after death, and accidentally or criminally. The mother confessed that the child was born alive, and had cried, but that it had died in five minutes after its birth. Its body was buried, and it was assumed that the wounds might have been accidentally inflicted after death by a spade, which had been used for the burial. The medical witness attributed death to the wounds, which, in his opinion, could not have been accidentally produced, but very properly admitted, in cross-examination, that the wounds would have presented the same appearances had they been inflicted immediately after death, while the blood was in a fluid state. Answers to questions of this kind can of course be given only in those cases in which the body has been examined soon after the infliction of the wounds. It would be extremely hazardous to pronounce an opinion when the child has been long dead. In the case of the Queen v. Taylor (York Lent Assizes, 1843), the child had been dead about a year, and when its body was found in a garret, it was so much dried up, that the medical witnesses were unable, with certainty, to state the sex. The left arm had been removed from the body, and on the throat was a cut extending nearly from ear to ear, which was considered to
have been made by some sharp instrument; and from the re-
traction of the edges of the wound, the witnesses thought that it
must have been produced during life or immediately after death.
The prisoner was acquitted. In this case there do not appear to
have been any good medical reasons for the opinion expressed
respecting the time at which the wound had been caused. Cer-
tainly, the retraction of the edges could furnish no evidence in a
wound produced a year before, and in a body so dried up as to
render the recognition of the sex difficult. This may have been
a case of child-murder, but there was no medical proof of it:
it was not even proved that the child had come into the world
living. Incised wounds found on the bodies of children may be
referred to the use of a knife or scissors by the prisoner, in at-
temptsing to sever the navel-string, and therefore be due to
accident. This point should not be forgotten, for a wound even
of a severe kind might be thus accidentally inflicted. In such
cases we should always expect to find the navel-string cut, and
not lacerated. The end of it may, for the purpose of exami-
nation, be stretched out on a piece of white card. In the case of
the Queen v. Wales (Central Criminal Court, Sept. 1839), it was
proved that there was a wound on the right side of the neck of
the child, not involving any important vessels, although it had
caused death. The medical witness allowed that it might have been
accidentally inflicted in the manner suggested, and the prisoner
was acquitted. As this question may be unexpectedly put at a
trial, a witness should prepare himself for it by a careful exa-
mination of the wound and of the navel-string. This will in
general suffice to show, whether an incised wound has been pro-
duced accidentally in the manner alleged, or by criminal design.

Slight marks of external violence should not be overlooked:—
minute punctures or incisions externally may correspond to deep-
seated injury of vital organs. The spinal marrow is said to have
been wounded by needles or stilettoes introduced between the
vertebrae, the skin having been drawn down before the wound was
inflicted, in order to give it a valvular character, and to render it
apparently superficial. The brain is also said to have been
wounded by similar weapons, through the nose or the thinner
parts of the skull (the fontanelles).

In some cases the body of a child is found cut to pieces, and
the allegation in defence may be that the child was still-born,
and the body thus treated merely for the purpose of concealment.
Dr. Toulmouche has reported a case of this kind, which was the
subject of a trial in France in 1852. As the woman had not
destroyed the lungs, experiments on these organs gave satis-
factory results of perfect respiration. The cavities of the heart
and great vessels were empty: the body was generally drained of
blood, and the skin throughout very pale. This led to the in-
fERENCE that the mutilations must have been inflicted while the
child was living, and as all the parts were healthy, and no natural cause of death apparent, Dr. Toulmouche ascribed the death of the child to the wounds inflicted. The woman was convicted, and condemned to twenty years' confinement in the galleys. (Ann. d'Hyg. 1853, ii. 200.) In this country she would probably have escaped under a verdict of concealment of birth, and have been sentenced to a year's imprisonment.

**Marks of violence on the head.**—It has been elsewhere remarked (antÈ, p. 489) that in a protracted delivery there is on the head of the child a tumour containing either serum, blood, or a mixture of the two. Non-professional persons may, when a woman has been secretly delivered, ascribe a tumour or this kind to violence, whereas it may really have been produced by natural causes. The tumour is generally situated on one of the parietal bones, its situation depending on that part of the body which presents during delivery. After the discharge of the waters, the scalp is firmly compressed by the mouth of the uterus, and subsequently by the os externum. This pressure interferes with the cutaneous circulation, and causes the compressed portion of scalp to swell. In the simplest form of this tumour serum only is found in the swollen part; occasionally this is mixed with blood, and there are small ecchymoses of the scalp, as well as of the pericranium and skull, but there is no injury to the bones, nor is there any laceration of the skin externally. In other cases blood is found diffused in the tumour either under the scalp, the membrane covering the skull (pericranium), or within the skull itself. The term *cephalematoma* or *caput succedaneum* is applied to tumours which have this natural origin. The sanguineous variety is much more likely to be confounded with the effects of violence than the serous tumour; but it is identified by the scalp being always uninjured, although this may present redness and lividity. Violence from blows or falls which would produce bloody effusion beneath the scalp, or within the skull, would in general be indicated by injury to the skin or by fracture of the bones. At the same time the following case, which occurred to Dr. West, shows that caution is required in forming an opinion.

In this case the child died twenty-three days after birth. The tumour (*cephalematoma*) was about the size of a walnut originally, but it extended so as nearly to cover the right parietal bone. On dissection, it was found to be filled with coagulated blood, beneath which was a layer of dense fibrinous matter. The right parietal bone presented a fissure with clean edges running from the coronal suture obliquely backwards and upwards. On the inner surface of the bone was an effusion of blood between the cranium and dura mater more than half an inch in thickness, and occupying the whole of the hollow of the parietal bone. There is no reason to doubt that the fracture and effusion were the results of compression during delivery. They had not been...

Fractures of the skull.—The only injuries which require to be specially considered in relation to infanticide, are fractures of the skull; and here the question to which we may confine our attention is, whether the fracture arose from accident or criminal violence. Although it has been a matter of frequent observation, that great violence may be done to the head of a child during parturition, without necessarily giving rise to fracture, yet it is placed beyond all doubt that this injury may occur by the expulsive efforts of the uterus forcing the head of a child against the bones of the pelvis. Even the violent compression which the head sometimes experiences in passing the mouth of the uterus, may suffice for the production of fracture. (See Ed. M. and S. J. xxvi. 75.) Until within the last few years, it had been generally supposed that fractures of the cranium in new-born children were always indicative of criminal violence; but the cases collected by Dr. Schwörer of Freiburg, and others, have established the certainty of their accidental occurrence. These accidental fractures, it is to be observed, are generally slight; they commonly amount merely to fissures in the bones, beginning at the sutures, and extending downwards for about an inch or less into the body of the bone. According to Dr. Weber, the frontal and parietal bones are the only bones liable to be fissured or fractured during the act of parturition. American Jour. Med. Sci. Jan. 1853, p. 254. (American edition of this work, by Dr. Hartshorne.) In the greater number of cases reported, the parietal bones only have presented marks of fracture.

The following case occurred to Dr. Schwörer while performing his duties at the Obstetric Institution:—The child was still-born; he received it into his hands at birth, so that the head could have sustained no outward violence. On inspection, the skin over the summit was found swollen; and on removing it, there was a large effusion of blood beneath, especially over the right parietal bone. The bone was fractured or fissured in two places. Blood in a half-conglutated state was found beneath the fissures, between the bone and the dura mater, as also between this and the tunica arachnoides. (Beit. zur Lehr. v. d. Kindermord, Freiburg, 1836.) Here, then, were all the signs indicative of external violence; and possibly, had this woman been delivered in secret, and the body of the child found in a concealed place, she might have been charged with the murder. A second case is reported in Casper’s Wochenschrift (Oct. 1840), in which about half a drachm of blood was effused on the right parietal bone, which was compressed in the centre, and presented a radiated fracture. Coagula were found on the dura mater. (See also B. and F. Med. Rev. xxi. 254, and vii. 333.) In a third case, where there
was deformity of the pelvis, the child was born dead, and there were two fissures, about an inch long, in the left parietal bone; and both parietal bones were considerably flattened. (Casper's Wochenschrift, Sept. 1837.) Dr. West has reported the following case of spontaneous fracture of the left parietal bone, which occurred to Dr. Götz, during a natural but tedious labour, in which the head of a child was five hours in the pelvic cavity, although the pelvis was well formed. There were three fissures in the bone; one running into the sagittal suture, one to the anterior inferior angle, and the other to the middle of the anterior edge of the bone. The child was still-born. Much blood was effused beneath the scalp, but none under the skull. (Med. Gaz. xxxix. 288.)

In respect to these accidental fractures and extravasations, it may be remarked that they are in general recognised by their very slight extent. In cases of murder by violence to the head, the injuries are commonly much more severe; the bones are driven in,—the brain protrudes, and the scalp is extensively lacerated. Such severe injuries as these cannot arise accidentally from the action of the uterus during parturition. In these cases, however, it may be fairly urged, that the woman was unexpectedly seized with labour, that the child was expelled suddenly by the violent efforts of the uterus, and that the injuries might have arisen from its head coming in contact with some hard surface—as a floor or pavement. It must be admitted, that a woman may be thus suddenly and unexpectedly delivered while in the erect posture, although this is not common among primiparous females; and that injuries may be thus accidentally produced on the head of a child.

_Sudden delivery in the erect posture._—A case of sudden delivery in the erect posture in a primiparous female, without injury to the child, is reported by Dr. W. Burke Ryan, in the Lancet, (June 21, 1845, p. 707.) The umbilical cord was in this instance ruptured at the distance of about two inches from the navel. This gentleman has communicated to me the particulars of a second case, which occurred in his practice in Oct. 1852. A woman who had borne a child was suddenly delivered while standing. The child fell to the floor on its vertex, and the cord was ruptured. A small quantity of blood escaped from the part struck, but there was no open wound or fracture of bones. The child sustained no injury. In another case of a primiparous female, sudden delivery took place while the woman was in the act of sitting down. The child was forcibly expelled, and fell with its head on the floor of the room. It was taken up dead, the cord being still attached to it and the placenta, which came away shortly after the birth of the child. (Med. Gaz. xxxvii. 808.) It would appear from cases collected by Dr. Klein, that fractures of the cranium under these circumstances are of rare occurrence. *Out of one hundred and eighty-three cases reported*
by him in which the women were rapidly delivered while sitting, standing, or inclined on the knees,—the child falling on the ground or floor, there was only one instance in which the child was killed; and there was not a single case in which the bones of the cranium were fissured or fractured, so far as could be ascertained by external examination. (Devergie, i. 631; Briand, 271.) Chaussier performed some experiments on the bodies of still-born children, allowing them to fall with their heads downwards on a paved floor, from a height of eighteen inches: and he found that out of fifteen cases one or other of the parietal bones was fractured in twelve. Although these results are conflicting, yet Klein’s observations appear more to the purpose; because they were made under circumstances in which the question would really arise in a case of infanticide. They are strikingly supported by the following case, which occurred to Mr. Blacklock. (Lancet, July 26, 1845.) A married woman was suddenly delivered while standing:—the child fell to the floor, but sustained no injury. The umbilical cord was ruptured close to the umbilicus. (See, also, Dr. Ryan’s case, supra.) A case analogous to these, also in a primipara, is reported in the Gazette Médicale, 26 June, 1847. A woman, at 27, was delivered of a child while in the act of walking to the hospital, at the distance of a mile. She stated that she had lost a large quantity of blood. The child, which she brought in her apron, was mature and living: the umbilical cord had been ruptured close to the abdomen. (See also another case by Dr. Pickford, Med. Gaz. vol. xlii. p. 731.) A still more recent case has been reported by Mr. Dermott. (Lancet, March 12, 1853, p. 245.) A young married woman, at 23, pregnant of her first child, was delivered suddenly while in the erect posture. The child, which was healthy and full-grown, fell upon the floor and the cord was broken off within three inches of the navel. It was separated as cleanly as if it had been done by an accoucheur. Excepting the production of a swelling on the forehead from a bruise, it had sustained no injury by this very sudden expulsion. A similar case occurred to Dr. Chevers. (Med. Jur. for India, 1856, p. 523.) These observations lead to the inference that such accidents are not very likely to occur; yet we cannot deny the possibility of their occurrence; therefore a barrister is fully justified in endeavouring upon this ground to exculpate a person charged with child-murder.

Dr. Swayne, of Bristol, has published in the Association Journal (Oct. 14, 1853, p. 901) a case which shows that a fracture of the skull of a child may occur when a woman is delivered in the erect posture. In this case, there was merely the appearance of a bruise on the head; the cord was ruptured (not cut) three inches from the navel. The child did not suffer from the fall, and continued well until six days after its birth, when it was seized with convulsions and died. A fracture of the skull was seen.
and a half in length was found in the upper part of the left parietal bone. A clot of blood was found in this situation, between the dura mater and bone, and there was congestion of the vessels of the membranes; with this exception there was no morbid appearance in the body. Dr. Porter Smith, of Bath, has communicated to me a case which occurred in November, 1856, in which the facts were similar to those above related. In consequence of the concealment of the body, however, the mother was charged with the murder. The right parietal bone was fractured, and there was effusion of blood internally, but there was no mark of external violence. The cord had been ruptured at a distance of two and a half inches from the navel. The stomach of the child contained the usual albuminous and mucous matters of the fatal state, without any appearance of food. The lungs were inflated and highly crepitant. The foramen ovale and the ductus arteriosus were in their fetal condition. The child had probably been drowned in the discharges from want of assistance at the time of birth. The woman was acquitted. She admitted that the child fell from her suddenly.

A medical witness would find no difficulty in determining the probability of this explanation of the accidental origin of such fractures, if he were made acquainted with all the facts connected with the delivery. But the acquisition of this knowledge must be accidental; and it will in general be out of his power to obtain it. Sometimes the fractures will be accompanied by incisions, punctures, or lacerations of the scalp or face:—in this case, although the origin of the fractures might be accounted for by the alleged fall during parturition, the cause of the other injuries would still remain to be explained. (See the case of the Queen v. Reeve, Cent. Crim. Court, Feb. 1839. The Queen v. Stevens, Bodmin Lent Ass., 1845.) Injuries of this nature, with the fact that there are bruises or contusions, as well as fractures not connected with each other in various parts of the skull, would be inexplicable on the hypothesis of an accidental fall. I am indebted to Mr. Keeteven, of Holloway, for the following case. An inquest was held in Feb. 1854, on the body of a female infant, of which a young woman had been delivered on the 21st of December, 1853. The infant had been born, according to the statement of the mother, in the pan of a water-closet on the ground floor of the house, and was afterwards carried by her up two pairs of stairs, and placed beside her in bed. She admitted that the child had been born alive, but stated that it was dead when she lifted it up from the pan to carry it to the bed-room. The umbilical cord was torn at the distance of four inches from the abdomen. The child, she alleged, had fallen into the water-closet pan. No trace, however, of blood or other discharge was found on or near the seat of the closet, while upon the opposite side of the chamber the floor was stained with blood, which had been imperfectly wiped up. On an examination of the body of
the infant, it was found to be a well-formed mature child, weighing seven pounds. The lungs had been fully expanded to their margins, covering the heart, and floating in water with or without the latter organ. The scalp presented no trace of injury. The usual tumour of the scalp was apparent. On dividing the scalp, there was some ecchymosis at this part. The bones of the skull were found extensively fractured. There was a horizontal fracture nearly an inch long over each orbital prominence; upon the right frontal eminence the bone was broken and depressed, in an acute triangular form, three quarters of an inch in length; the parietal bones on each side were fractured vertically from their eminences downwards to the extent of an inch and a quarter; on the left side the lower end of this fissure was joined by another of similar extent, passing horizontally forwards at a right angle to the edge of the bone. Several minor fractures were found at different parts of the upper surface of the skull; they were not apparently connected with each other. Within the cranium, blood was extravasated on the surface of the brain, and in the membranes. No fractures were detected at the base of the skull. The mother alleged that the injuries to the head were owing to the child having fallen into the pan of the water-closet. This explanation, however, was inadmissible, as it was very doubtful whether the body of the child had been in the pan at all. Even supposing the child to have thus fallen, the distance was too small to have caused such an amount of injury situated on various parts of the skull; besides which, as the child would have passed in an oblique direction forwards, from the outlet, it would have glided safely down the side of the pan. In the absence of all evidence as to how the injuries were inflicted, it was suggested that they might have been caused by the mother having fallen upon the child on her way up stairs; and this hypothesis was ultimately adopted by the coroner's jury. There was no doubt that the child's death was caused by the injuries to the head, and the jury took, what is called, a very lenient view of the facts, in rejecting the woman's explanation of the cause of the violence, and in assuming that such a variety of severe injuries to the bones of the head could have been produced by the mother falling upon the body of the child. (See another case in Med. Times and Gaz. April 4, 1857, p. 347.)

The medico-legal importance of this subject will be further apparent from the evidence given in a case tried before the Criminal Court of New York, in November, 1834. (Med. Gaz. xviii. 44.) One of the medical witnesses in this case positively denied that the bones of the head could be fractured by the action of the uterus during parturition! It appeared highly probable that the fracture had been here occasioned by the accidental fall of the child during delivery; and the prisoner was acquitted. Dr. Wharrie has published a case, also the subject of a criminal charge, in which it is probable that a fracture of the head of
a child was produced by the explosive action of the uterus. The body had been found secretly buried. It was fully developed, but had evidently not breathed. The navel-string had been cut and tied; six inches of it still remained attached to the body. On the left side of the cranium, near the vertex, there was a small effusion of blood; and on removing this, a fissure half an inch in length was found in the edge of the left parietal bone, close to the line of the sagittal suture, and near the posterior fontanelle. On shaving off the hair, there was no discoloration, nor any mark on the skin indicative of a blow. There was no evidence to show that any violence had been used to the child at its birth, and from the description of the fissure it was a fair presumption that it had arisen during delivery from the muscular contractions of the uterus. (Cormack’s Monthly Jour. Nov. 1845, p. 847.)

The possible occurrence of an injury of this kind has been strained, in several cases of child-murder, to explain the origin of fractures which, however, could not be fairly assigned to such a cause. A case was tried at Glasgow, in April 1852 (case of Ann Irwin), in which Dr. Easton gave evidence. There was no doubt, from the state of the lungs, that the child had fully breathed, and there was violence to the head which satisfactorily accounted for death. The whole extent of the right side of the head was deeply ecchymosed, and there was a considerable amount of coagulated blood lying between it and the cranium. In the centre of the right parietal bone, there was a fracture extending across the vertex for fully four inches, and involving a part of the parietal bone on the opposite side. The fracture was a continuous even line, not radiated and not depressed. The pericranium, bones, and soft parts in the track of the fracture, were deeply ecchymosed, while on the surface of the brain, particularly on the right hemisphere, there was a copious effusion of clotted blood. It was impossible to refer severe injuries of this kind to the action of the uterus in delivery, or to violence applied after death. The prisoner alleged that the child was still-born. (See Edinburgh Monthly Jour., June 1825.) In the case of the Queen v. Mussett (Bury, Lent Assizes, 1856,) the head of the child was almost flattened from the violence sustained. It was clear that no fall or other accident would explain this condition. Some fresh blood and a single hair were found on a shelf in the collar, for which the prisoner accounted by stating that she had there killed a rabbit. A microscopical examination, however, showed that it was a human hair. The medical evidence established from the state of the lungs that the child had breathed, and that it had had an independent existence. The prisoner was convicted.

**Length of the umbilical cord.**—It has been recommended on these occasions, that we should observe the length of the umbilical cord, and notice whether it be cut or lacerated, as these facts
may, it is presumed, throw some light on the question. But a medical witness can seldom procure the cord for examination, although it will generally be in his power to ascertain whether it was cut or lacerated, by examining the portion which is attached to the body of the child. The cord varies in length,—the average being from eighteen to twenty inches: but it has been met with so short as six inches (Lancet, June 13, 1846, p. 560.) and even five inches. (Lancet, July 11, 1846, p. 49.) In a twin case which occurred to Mr. Stedman, of Guildford, the cord was only four inches long. (Lancet, Aug. 28, 1841.) On the other hand, in one instance, where it was found twice twisted round the child’s neck, it was fifty-three inches long. Dr. Churchill found, out of three hundred and ninety-one cases, that the shortest cord was twelve inches, and the longest fifty-four inches in length. In a case reported by Mr. Wood it was sixty-one inches long, and coiled twice round the abdomen of the child. (Med. Gaz. xliv. 263.) As the whole of the cord can rarely be obtained, it is unnecessary to discuss the question, whether it was long enough to admit of the falling of the child without rupture. It has been remarked, that when the cord is ruptured from accidental causes during delivery, the rupture takes place either very near to the placental or the umbilical end. In twenty-one of the cases observed by Klein, it was found to have been forcibly torn out of the abdomen; but it may be torn or lacerated at any part of its length, although the rupture is commonly observed near to one extremity. It does not appear how the examination of the cord can throw any light upon the origin of these fractures of the cranium.

Injuries accidentally sustained in utero.—A practitioner must remember that if, while in an advanced stage of pregnancy, a female should accidentally fall, the child may sustain injury by a blow through the abdominal parietes. This is not to be strained into a specious defence for violence which has obviously occurred subsequently to birth, but the fact itself is of sufficient importance to merit attention, as the following case will show:—A pregnant woman, within five days of the ordinary term of gestation, fell while running, so that her abdomen struck sharply against an angular stone. There was an immediate loss of blood, and the movements of the child ceased. Four days after the accident, parturition came on. Dr. Stanelli found the head of the child much enlarged, and in a putrid state. The female died in an hour. On examining the child, the skull was found almost crushed, the parietal having become separated from the temporal bones as if by external violence. The marks of injury were entirely limited to the head. (Gazette des Hôpitaux, Nov. 7, 1846, p. 523.)

In accidents of this kind it is most probable that the child would be born dead. There might also be marks of violence on the abdomen of the mother. Some observers have described
cases in which the limbs of the fetus in utero have become deeply indented or spontaneously amputated, by the twisting of the umbilical cord around them. (Dublin Hospital Gazette, Jan. 1846, 153.) It is not possible that these or other accidental injuries before birth, could ever be mistaken for violence inflicted on the body of a child after its birth. A remarkable case of this kind has been communicated to the Med. Times and Gaz. (Dec. 10, 1853, p. 604) by Mr. Maclauglin, in which a child was born without limbs. It is difficult to account for the occurrence of such a singular case as this: but practically it could have occasioned no medico-legal difficulty, had the body of the child been found dead, since the absence of the limbs could not have been referred to an act of mutilation. Dr. H. Barker, of Bedford, has directed attention to the subject of intra-uterine fractures, in their pathological and medico-legal relations. He advises that the bones of the body should be examined, in reference to their strength, osseous development, and other physical characters. It will probably be found, as in fractures in adults from slight causes, that the bones are preternaturally brittle (ante, p. 381). In this case, due allowance should be made for the occurrence of an intra-uterine fracture, as the result of a fall during pregnancy. (On Intra-uterine Fractures, p. 21. 1857.)

Defective ossification simulating violence.—In reference to injuries of the bones of the head in a new-born child it may be proper to mention the particulars of a case referred to me by Mr. Lord, of Hampstead, in 1847. The dead body of a new-born child, wrapped in brown paper and a towel, was found in a pond. Mr. Lord examined it for the coroner's inquest. The head was much decomposed, and the scalp was extensively lacerated and destroyed over the parietal bones, which readily separated. The brain was reduced to a bloody pulp. The umbilical cord, which had not been tied, was cut obliquely at about six inches from the umbilicus. The lungs, which were very crepitant, readily floated on water, and bore up the heart. The body was generally bloodless. The point of difficulty which the case presented, consisted in the presence of two apertures on one parietal bone. These apertures were small and rounded, and it was at first doubtful whether they had not been wilfully produced by some perforating instrument applied to the head. It was remarked that one aperture was situated near the temporal ridge and in this situation the scalp was entire and uninjured. The other was situated in that part of the bone which corresponded to the lacerated portion of scalp. It was ascertained that no violence had been used in the removal of the body from the water. The bone was macerated, and carefully examined by the aid of a lens. It was then perceived that the apertures were quite regular at the edges, which were remarkably thin, evidently passing into a membranous condition. The internal table was also deficient, so that from the interior, the bone was bevelled off gradually.
from each aperture. This examination left no doubt that the holes in the bone were not due to any mechanical violence applied during life, but to deficient ossification. These spaces had been membranous, and the membrane destroyed by decomposition. The putrefaction of the scalp, and its separation, might have been accelerated by a bruised condition of these parts during a difficult labour.

**Twisting of the neck.**—Children are sometimes destroyed in the act of birth by the neck being forcibly twisted, whereby a displacement of the cervical vertebra, with injury to the spinal marrow, may occur, and destroy life. Such injuries are immediately discovered by an examination. It should be remembered, however, that the neck of a child is very short, and that it always possesses considerable mobility.

**Violence in self-delivery.**—When the marks of violence found on the head, neck, and body of a child, cannot be easily referred to an accidental fall, it is very common to ascribe them to the efforts made by the woman in her attempts at self-delivery, and without any intention on her part of destroying life. The rules to guide a medical opinion in such a case must depend upon the nature, situation, and extent of the injuries; and each case must be therefore decided by the circumstances attending it. (The Queen v. Horder, Abingdon Summer Ass. 1840.) This should be contrasted with two other cases (the Queen v. Trilloo, Hereford Summer Ass. 1842; Queen v. Turner, Worcester Winter Ass. 1843.) In the two first cases, the children were admitted to have been living;—in the one the violence was chiefly confined to the head, and the prisoner was acquitted,—in the other the marks of violence were upon the neck, and the prisoner was convicted. These cases show the uncertainty attendant on a plea of this kind.—(See also two other instances, B. and F. Med. Rev. viii. 591.) Sanguineous tumours simulating fractures are sometimes found on the heads of new-born children. These depend on natural causes, and must not be confounded with marks of violence. (Med. Gaz. xxxvi. 1082.) They may be known by the unruffled state of the skin. A medical witness, however, must be prepared to allow that a woman at the time of her delivery, may from pain and anxiety become deprived of all judgment, and may destroy her offspring without being conscious of what she is doing. It is therefore a sound principle of law that mere appearances of violence on a child’s body, are not *per se* sufficient, unless there be some evidence to show that the violence was knowingly and intentionally inflicted, or the appearances are of such a kind as of themselves to indicate intentional murder. (Alison.) The benefit of a doubt will always be given in favour of the accused. See **Puerperal Mania**, post.

**Conclusions.**—The conclusions to be derived from the contents of this chapter are;—
1. That a new-born child may die from violent causes, arising from accident.
2. That some forms of violent death are not necessarily attended with external signs indicative of violence.
3. That a child may be accidentally suffocated during delivery.
4. That the usual marks of death from drowning are not apparent, except in children which have breathed.
5. That the state of the umbilical cord may often furnish important evidence.
6. That some females recently delivered, may have strength to exert themselves and walk great distances,
7. That a new-born child may speedily die from exposure to cold and privation of food.
8. That slight fractures of the bones of the cranium may arise from the action of the uterus on the head of the child during delivery.
9. That females may be unexpectedly delivered while in an erect posture: the umbilical cord is, under these circumstances, sometimes ruptured, and the child may sustain injury by the fall.
10. That the violence found on the body of a child may be sometimes referred to attempts innocently made by the female to aid delivery.

CHAPTER XLVI.

Among the forms of violent death, which are almost always attended with appearances indicative of criminal design, are the following:

7. Strangulation. — The destruction of a new-born child by strangulation is not an unfrequent form of child-murder: and here a medical jurist has to encounter the difficulty, that the strangulation may have been accidentally produced by the twisting of the umbilical cord round the neck during delivery. We
must not hastily conclude from the red and swollen appearance of the head and face of a child, when found dead, that it has been destroyed by strangulation. There is no doubt that errors were formerly made with respect to this appearance; for Dr. Hunter observes,—"When a child’s head or face looks swollen, and is very red or black, the vulgar, because hanged people look so, are apt to conclude that it must have been strangled. But those who are in the practice of midwifery, know that there is nothing more common in natural births, and that the swelling and deep colour go gradually off if the child live but a few days. This appearance is particularly observable in those cases where the navel-string happens to gird the child’s neck, and where its head happens to be born some time before its body."—(Op. cit. 27.) Strangulation by the umbilical cord can of course refer to those cases only in which the cord becomes firmly twisted round the neck after the respiratory process is established, and this is rather a rare occurrence; because death more commonly takes place by compression of the cord under these circumstances, and by the consequent arrest of circulation before the act of breathing is performed. The only internal appearance met with in death from this cause, is a congested state of the cerebral vessels. The appearance of ecchymosis on the scalp, as well as lividity of the face, is very common in new-born children when the labour has been tedious and difficult; and, therefore, unless there were some marks of injury about the neck, this would not justify any suspicion of death from strangulation.

Strangulation by the umbilical cord.—It has been supposed, that the strangulation produced by the wilful application of any constricting force to the neck, would be known from the accidental strangulation caused by the cord, by the fact that in the former case there would be a livid or ecchymosed mark or depression on the neck. But it may be objected to this view, that such a mark, although, from the great violence used, a common, is not a constant accompaniment of homicidal strangulation. On the other hand, although it was formerly a disputed question, it is now certain that the umbilical cord may itself produce, in some instances, a livid or ecchymosed depression. Among various cases which might be quoted in support of this view, is the following reported by Mr. Foster. In April 1846, he was summoned to attend a lady in labour with her first child. Owing to the size of the head, the labour was of a lingering kind, and the child came into the world dead. The umbilical cord was found coiled three times round the neck, passing under the right armpit; and upon removing it, three parallel discoloured depressions were distinctly evident. These extended completely round the neck, and corresponded to the course taken by the umbilical cord. The child appeared as if it had been strangled. (Med. Gaz. xxxvii. 485.) Had this child been born secretly, this
state of the neck might have created a strong suspicion of homicidal violence. Strangulation after birth could not, however, have been alleged, because there would have been no proof of respiration. When a blue mark is found on the neck of a child whose lungs retain their fetal characters, it is fair to presume, ceteris paribus, that it has been occasioned accidentally by the twisting of the umbilical cord during delivery. Mr. Price has communicated to the same journal the account of a case in which the cord was so tightly twisted around the neck of a child, that he was compelled to divide it before delivery could be accomplished. There was in this case a deep groove formed on the neck, and it conveyed the impression to himself and a medical friend, that, in the absence of any knowledge of the facts, they would have been prepared to say that the child had been wilfully strangled by a rope. (Med. Gaz. xxxviii, 40.) In this instance the cord was very short. A diagnosis might have been formed, as in the preceding case, by examining the state of the lungs. Dr. Mutter met with a case in which the child was born dead, and the cord was tightly twisted round its neck,—when removed, the neck exhibited a livid circle of a finger’s breadth, smooth, and shining; but on cutting into this mark, no subcutaneous ecchymosis was found. (North. Jour. Med., Jan. 1845, p. 190.)

From two of these cases it will be perceived that by trusting to ecchymosis in the mark as an absolute means of distinction between constriction produced by criminal means, and that which results accidentally from the umbilical cord, a serious error may be committed. As in the following case (reported in the Ann. d’Hyg, 1841, i, 127,) a female charged with the murder of her child by strangulation may be unjustly condemned. The child had fully and perfectly respired:—the lungs weighed one thousand grains, and when divided, every portion floated on water, even after firm compression. There was a mark on the neck, which was superficially ecchymosed in a part of its course. From an investigation of the facts, this appeared to have been a case in which the mark was produced accidentally by the umbilical cord, during attempts at self delivery on the part of the woman, i. e. by her manipulations with the cord. She was, nevertheless, convicted, and condemned to a severe punishment. The case establishes three points: 1, that partial ecchymosis may be produced on the neck by the umbilical cord being twisted around it; 2, that this may lead to the accidental strangulation of a child after it has breathed at the outlet,—the cord was twenty-four inches long; 3, that a child’s lungs may in a few seconds become sufficiently distended with air to give satisfactory evidence of respiration with the pulmonary tests. In the same journal, p. 428, will be found the report of another case, suggesting many important reflections in regard to the medical jurisprudence of infanticide. In this instance the umbilical cord and membranes
were actually used by the female as a means of strangulation; the child had not breathed, but was thereby prevented from respiring. There was superficial ecchymosis on each side of the neck over the sterno-clidio-mastoidei muscles. The defence was, that the child was born with the cord around its neck, and that it was from this circumstance accidentally strangled; but the medical evidence tended to show, that the cord had been violently stretched and used as a means of strangulation. The child had not breathed, and the witnesses considered it to have been born dead, owing to the violence used by the woman. The cause of death here was certainly not strangulation, but arrested circulation. In the meantime, the case proves that ecchymosis (a blue mark) may be the result of the constriction produced by the cord. (For additional remarks on this subject, see Henke's Zeitschrift, 1837, iv. 352; also Ed. M. and S. J., Oct. 1838, p. 282.) A case occurred to Mr. M'Cann, in September 1838, in which the umbilical cord, which was of its full length, had been used as the means of strangulation. It was twisted once round the neck, passed under the left arm over the shoulders, and round the neck again, forming a noose or knot, which, pressing upon the throat, must have caused strangulation, as the tongue was protruded, and there were other clear indications of the child having been strangled. The hydrostatic test applied to the lungs proved that respiration had been performed.

**Distinction.**—When the mark is deep, much ecchymosed, and there is extravasation of blood beneath, with ruffling or laceration of the skin, it is impossible to attribute this to the effect of the umbilical cord. The lividity produced by the cord in the cases hitherto observed, has been only slight and partial, and unaccompanied by laceration of the skin, or injury to deep-seated parts. (For an instructive case by Dr. Scott, in reference to this point, see Ed. M. and S. J. xxvi. 62.) On the other hand, in homicidal strangulation, much more violence being used than is necessary for destroying life, we may commonly expect to find great ecchymosis and extensive injury to the surrounding soft parts. On some occasions, all difficulty is removed by the discovery of a rope, tape, or ligature round the neck: or if this be not found, the proofs of some ligature having been used will be discovered in the indentations or irregularly ecchymosed spots left on the skin, the depressed portions of skin being generally white, and the raised edges livid.

It is questionable whether a child can be born with the umbilical cord so tightly round the neck, as to produce great depression of the skin and ecchymosis, i.e. to simulate homicidal strangulation, and at the same time perform the act of respiration fully and completely. It is important, therefore, when this hypothesis is raised in order to account for the suspicious mark on the neck, to examine closely the state of the lungs. Unless the cord
be designedly put round the neck of the child after the head has protruded, the effect of the expulsive efforts of the uterus, when a coil had become accidentally twisted round the neck, would be to tighten the cord, compress the vessels, and kill the child, by arresting the maternal circulation, at the same time that this pressure would effectually prevent respiration. The lungs, as in the cases above cited, should present the appearances met with in still-born children. This point is frequently lost sight of in medical evidence; and marks produced by ligatures wilfully applied, are set down as having been caused by the cord. In the case of Reg. v. Prayle, Oxford Summer Ass., 1853, the mark on the child’s neck was attributed to the navel-string. In the case of Reg. v. Robinson, Lewes Summer Ass., 1853, there was the mark of a ligature round the neck which had been tied very tightly,—the child had fully breathed, and according to the medical evidence it had died of strangulation. The strangulation was referred to an accidental twisting of the cord during delivery. It is to be feared that this kind of defence is too readily accepted by medical witnesses in cross-examination. In examining a suspicious mark round the neck of a new-born infant, it is desirable to notice whether it does not, by its form or course, present some peculiar indentations, which may render it certain that a ligature had been employed after birth. When it is found that a child has fully respired, the presence of a deeply ecchymosed mark on the neck is ceteris paribus presumptive of homicidal strangulation. Death from accidental constriction of the cord should as a general rule leave the lungs in their fetal condition.

Marks on the neck may be produced by the umbilical cord without necessarily destroying the child’s life. Two cases of this kind are reported by Prof. Busch. (Br. and For. Med. Rev. x. 578.) Or the child may be destroyed without ecchymosis being a necessary consequence of the constriction produced by it. (See case by Dr. Hanff, Henke’s Zeitschrift, 1836, Erg. H.) There is much less risk of strangulation from twisting of the cord than is commonly believed. Out of one hundred and ninety cases, Dr. Churchill found the cord round the neck in fifty-two children. The shortest cord so disposed was eighteen inches long, and it occurred twice in seventy-five cases. Insulated or detached marks of ecchymosis, as from local pressure, cannot be set down to the twisting of the navel-string. Other accidental causes may here come into operation. In the case of Reg. v. Sampson (Bodmin Lent Assizes, 1853) it was proved that there was a mark on the neck of the child, and it was charged against the prisoner that this had been caused by pressure of the fingers, i. e. by pinching the wind-pipe. The mark was described as being red and inflamed, and an inch and a quarter in length. It was suggested in defence, that the mark might have been produced by the tying of a cap. The medical witness stated
that it was below the spot where a cap would be generally tied, but the mark might by possibility have been occasioned by the knot of the tie. The prisoner was acquitted. In admitting this kind of defence, it is to be observed that the tying of a cap may actually be made the means by which death by strangulation is effected.

Accidental marks resembling those of strangulation. — In the fore part of the neck of a child a mark or depression is sometimes accidentally produced by forcibly bending the head forwards on the chest, especially when this has been done repeatedly and recently after death. It may occur also as an accident during labour. Such a mark must not be mistaken for the effect of homicidal violence. It has been a question whether, independently of the constriction produced by the cord, the neck of the uterus might not cause, during its contractions, an ecchymosed mark on the neck. I am not aware that there is any case reported which bears out this view; and it seems highly improbable that any such result should follow.

The discoloration may be in detached spots or patches, — situated in the fore part of the neck, and evidently not arising from the employment of any ligature. These marks may depend on the forcible application of the fingers to the fore part of the neck of the child, and the indentations have been known to correspond, — a fact which has at once led to a suspicion of the cause of pressure and the mode of death. It may be alleged in defence, that such marks might have been accidentally produced: 1. By the forcible pressure produced by the child's head during labour, an explanation which is highly improbable, if respiration has been performed — although a child has been known to breathe in breech-presentations, while the head was still in the vagina. 2. They will be more commonly referred to the violent attempt made by a woman at self-delivery, during a paroxysm of pain. This explanation is admissible, so long as it is confined to injuries probably received during labour; but supposing the marks to have been certainly produced after birth, it will not of course apply. The following case (the Queen v. Ancliff, Nottingham Lent Assizes, 1842) is in this respect worthy of attention; for it appears to me to show that a defence of this kind may be sometimes strained: — The evidence proved that the prisoner was delivered of a child, under much suffering, on a stone floor, and in the presence of another woman, — a witness. The child was born alive, and was heard to cry several times. The witness left it in charge of its mother, and on returning shortly afterwards, she found it dead, with black marks upon its throat. The female midwife, who separated the child from the mother, deposed that it gave a sort of half-cry; — she thought it was dead when she first saw it, and the marks on the neck were not more than a woman might have caused in attempting
to deliver herself. The medical evidence showed that there were many ecchymosed marks about the throat of the child; and on the right side of the neck blood was effused. The marks might have been produced by the fingers: — death had been caused by pressure on the windpipe. The judge left it to the jury to say, whether the marks of violence might not have been unconsciously inflicted by the prisoner during labour. The jury returned a verdict of not guilty. (See also a case by Bellot, Ann. D’Hyg. 1832, ii. 205.) Among marks simulating violence, which are sometimes found on the necks of new-born children, Mr. Harvey has pointed out one of a very singular kind. In February 1846, he was present at a delivery in which a child was expelled rather suddenly; and after making two or three convulsive gasps, it died. Whilst endeavouring to restore animation, he observed a bright red mark extending completely across the upper and fore part of the neck, from one angle of the lower jaw to the other, exactly as though it had been produced by strangulation with a cord, except that the mark was not continued round to the back of the neck. It was of a vivid red colour, and not like a bruise or ecchymosis: it had very much the appearance of a recent excoriation. It was most clearly defined in front, where it was about a quarter of an inch in breadth, and it became diffused at the sides. The face was not swollen, and there was no fulness of the veins. (Med. Gaz. xxxvii. p. 379.) The distinction here would have been based upon the colour of the mark — the unabraded state of the epidermis, and the absence of congestion of the face and venous system. Nevertheless, the case is of great importance, and the facts should be borne in mind, in the examination of the body of a new-born child alleged to have been strangled. Another case, which was the subject of a coroner’s inquest, has been published by Mr. Rose in the same journal (xxxvii. 530), in which red marks on each side of the nose of a new-born child were mistaken for the effects of violence applied to the nostrils during a supposed attempt at suffocation. Mr. Rose examined them closely, and considered that they were navi, and had nothing to do with the death of the infant!

Constriction before or after death — before or after respiration. — A medical witness is sometimes asked to state on these occasions, whether the ligature or the fingers had been applied to the neck of the child before or after death, — or before or after it had breathed. It is proper to observe, that so far as the external marks of strangulation are concerned, there is no difference in the appearances, whether the constriction take place during life or immediately after death, while the body is warm. Casper’s experiments render it highly probable, that when the constricting force is applied to the neck of a dead child at any time within an hour after death, the marks cannot with certainty be distinguished.
Infanticide. Constriction After Death.

by any appearance from those made on a living body. (Wochenschrift, Jan. 1837.) With regard to the second point, it may be stated, that whether the child has breathed or not, provided it be living, the marks of violence present precisely the same characters. The following case is related by Casper:—The body of a new-born child was found concealed in a cellar, and the mother was charged with having murdered it. She confessed that she had heard the child cry at the birth, but that it soon died. In about an hour afterwards, she tied tightly round its neck a band made of a few straws, which she had hastily twisted together for that purpose, in order, as she alleged, "to prevent it from awaking." On the fifth day, the body was examined; the child was mature, well-formed, and had evidently breathed. The examiners referred death to strangulation; the woman was convicted, and sentenced to be imprisoned for life. An appeal was made against this sentence, and Casper's opinion was called for on the propriety of the medical inference of strangulation during life, from the mark on the neck. The witnesses had stated:—"that each straw in the band had produced a well-defined depression, which was whiter than the surrounding skin, while the little folds or elevations between the straws were red;—and on cutting into these reddened portions, slight ecchymosis was found beneath." Casper gave his opinion, that the slight ecchymosis observed, might have resulted from the application of the straw-band soon after death,—while the body was warm; and the circumstantial evidence allowed that the ligature might have been applied at some time within an hour after death. Hence he declared that there was a want of proof that this child had died from strangulation. In consequence of this opinion the punishment was mitigated. It is impossible to deny the correctness of the inference drawn by Casper, since the mark was undoubtedly such that it might have been produced either before or recently after death. Which of these two suppositions was the more probable, and whether it was more likely that a ligature should be put round a child's neck an hour after death to prevent it from awaking (!), or before death for the alleged purpose of destroying it, it was course for a jury, and not for a medical witness to decide. If there was nothing more in the prisoner's favour than her own statement as to the time when she applied the ligature and her object in applying it, it is certain that a very humane interpretation was put upon the facts. If the Court believed Casper's opinion to be correct, the woman should have been altogether acquitted, instead of having the punishment merely mitigated. It can be no crime, however absurd and accountable it may appear, for a person to place a ligature round the neck of a child after death, to give the appearance of strangulation. When such an extraordinary plea as this is raised, it is a fair matter of inquiry for a jury, to consider the motives of
human conduct, and to judge of such a defence on the principles of common sense. If carried too far, no one who was not seen by others to perpetrate the act, could be convicted of homicidal strangulation. In the case of the Queen v. Wren, tried at the Winchester Lent Ass., 1840, the medical evidence went to show that the child had breathed, and was born alive. There was a piece of tape tied round its neck very tightly, and fastened behind, and there was a discoloration of the skin beneath. The tongue was livid and swollen, and blood was effused beneath the scalp. The medical witness admitted that the mark on the neck might have been produced after death; and as he could not positively say that the child had been destroyed by strangulation, the prisoner was acquitted. (See also the Queen v. Hyland, Cent. Crim. Court, Aug. 1844.)

Constriction before or after entire birth. — Judging from what has occurred on several recent trials, a medical witness must prepare himself for another and a more difficult question. Let us suppose it to be admitted, that the ligature was applied to the neck of a child while it was living, and after it had breathed; — it still remains to be determined, whether it was applied before or after the legal birth of the child, or, as some judges have laid down the rule, before or after an independent circulation has been established in the child's body. In the case of R. v. Enoch, it was held "that there must be an independent circulation in the child before it can be accounted alive." (Archbold, 367.) By an "independent circulation," we can only understand that condition in which respiration is established, and the blood no longer passes from the mother to the child. Thus, this state would be proved by a cessation of pulsation in the cord, and the crying or audible respiration of the child. It will be seen that this is tantamount to insisting upon absolute proof of respiration, as evidence of life; and, therefore, entirely conflicts with the opinions of other judges, who have held that proof of respiration is not necessary on a charge of murder, because a child might be born alive and not breathe for some time after its birth. (R. v. Brain, Archbold, 367.) On the other hand, if the presence of an independent circulation be the test of a child being legally alive at the time of the violence, the entire birth of its body is certainly not necessary for this; because, as it is well known, respiration may be established and consequently an independent circulation acquired, before the body of the child is entirely born. Here, again, this judgment is opposed to the opinions of those judges who have repeatedly held that, whether a child has breathed or not, entire live birth must be proved. One of the most common judicial objections to the hydrostatic test is, that a child may breathe, i. e. substantially acquire an independent circulation, but die before its body is born. In this state of uncertainty, it is difficult to say what medical evidence
is required to prove. If an independent circulation alone is sufficient, it cannot be always necessary to prove entire live birth; but if proof of entire live birth be sufficient, then it cannot be always necessary to show that the child had acquired an independent circulation when the violence was offered to it! In a case of tenancy by courtesy, (Fish v. Palmer, 1806, 1st, Brum.) the judges of that time held that the quivering or spasmodic motion of a lip after birth, without respiration, independent circulation, or any other sign of vitality, was sufficient to show that that child was born alive—and that it had thereby acquired civil rights which it could transmit to others,—its heirs. Why is the proof of an independent circulation in a child to be demanded of medical witnesses in a case involving a question of its murder, when, in respect to its acquisition of civil rights, such a proof is not called for? If the question were fairly considered by all the judges, probably proof of an independent circulation in this sense would not be required: at any rate it could not be consistently demanded, in the face of other decisions, that proof of respiration was not absolutely necessary to constitute live birth in law, even in cases of child-murder. Among cases in which this question has been raised one occurred on the Oxford Spring Circuit, 1841 (the Queen v. Wright). The child was found concealed in a garden; its throat was completely cut, and there was a stab under the left arm. Gurney B. is reported to have stopped the case because there was no proof that the child had had "an independent existence" when the wounds were inflicted. It is worthy of remark, that one form of murder may be the actual prevention of the establishment of an independent circulation or existence in the child, as where the navel-string is designedly tied before the commencement of the respiratory process. It has been suggested that ignorance of this point, among midwives, may be a cause of numerous still-births. In the meantime one fact is obvious, that whether the means of strangulation, if that be the form of murder, be applied to the neck of a living child before the entire birth of its body or afterwards, —before the establishment of an independent circulation (i.e. the act of respiration) or afterwards,—the appearances will be the same; and from these it will be impossible to say, when the strangulation was accomplished.

Constriction before or after severance of the umbilical cord.—There is still another novel form which this question has taken. The witness may perhaps be asked whether the strangulation occurred before or after the umbilical cord was severed. It would appear that the severance of the cord has been sometimes regarded in law as a test of an independent circulation being established in the child—but this is obviously an error, depending on the want of proper information respecting the phenomena which accompany birth. Respiration, and therefore an independent circulation, may
exist before the cord is divided; and its severance, which is never likely to take place until after entire birth, cannot consequently be considered as a boundary between a child which is really born alive, and one which is born dead. A premature severance, as it was just now stated, might positively endanger the life of a child, instead of giving to it an independent existence. A healthy and vigorous child may continue to live and breathe independently of the mother, before the division of the cord, and the time at which the severance is made depends on mere accident. Hence the marks of strangulation on the neck of a living and breathing child must be the same, whether the cord be divided or not. The object of putting such a question is not apparent, unless it is intended to be implied that no child is legally born alive until the accoucheur or the woman herself chooses to sever the cord. It would therefore follow, on this doctrine, that to strangle a living child (entirely born) with the umbilical cord, provided this be not lacerated in the attempt, would not constitute infanticide! If this inference be incorrect, it is impossible to see what can have been the object of asking a medical witness such a question on these occasions. A case in which the cord was actually used as the means of destruction has been already given. (See ante, p. 516.)

The following cases will illustrate the difficulties which a witness may have to encounter when it is alleged that a child has been destroyed by strangulation. The first is that of Rex v. Crutchley (Monmouth Lent Assizes, 1837). In this case the body of the child was discovered by a medical man (one of the witnesses) under the bed of the prisoner, who had been secretly delivered. There was a riband tied in a knot so tightly round its neck, as to have prevented respiration. The child had evidently been dead some hours, and the prisoner alleged that it was born dead. On inspection, the face was found swollen and the lips livid; the lungs contained air, and were of a florid colour; they were crepitant and floated on water, so as to leave no doubt that the child had breathed. The vessels of the brain were gorged; the other viscera were perfectly healthy. He attributed death to strangulation;—he thought that the ligature had been placed round the neck before the umbilical cord, which had not been tied was secured; but the reason for this opinion is not stated. He considered that the child had been born wholly alive, but admitted that the ligature would have produced the same appearance on the neck, had it been applied before the complete birth of the child. Another witness, however, stated that he thought the ligature might have been placed round the neck before the entire body of the child was born. The defence was, that the ligature had been used by the woman for the purpose of assisting herself in the labour; and that the medical evidence allowed, whether this was the motive or not, that it had been
applied before the child was actually born. The judge desired the jury to consider, whether the prisoner wilfully killed the child;—if so, whether the killing occurred before or after the entire birth of its body,—and lastly, whether the killing took place while it was still attached to the body of its mother. Unless the child was destroyed after entire birth, the prisoner would be entitled to an acquittal;—if destroyed while still attached to the body of its mother, the point would be reserved for the consideration of the judges. The prisoner was acquitted. There can be no doubt that, provided a child be born entirely in a living state, the destruction of it would be murder, whether the cord were severed or not.

In the case of the Queen v. Byron (Chester Ant. Ass., 1835), the dead body of a child was found with a piece of rag tied round its neck, which in the opinion of the medical witness had caused death by strangulation; but on being questioned by the judge he admitted that the appearances might be explained by supposing that the prisoner had produced them in attempting to deliver herself. In the case of the Queen v. Milligate (Central Criminal Court, Nov. 1842), the child was discovered dead, and on examination the face was livid, the tongue protruded, and the hands were clenched. Around the neck was a ligature which had been passed round four times, and was tied tightly. The vessels of the brain were turgid, the lungs partially inflated, and the general appearance of the body was healthy. The medical witness thought that the child had been born alive, and had died from the effects of the ligature on the neck. The judge directed the jury that they must be satisfied that the child was completely born at the time the ligature was put round the neck. The prisoner was acquitted. In another case, the Queen v. Webster (Worcester Lent Ass., 1839), the following facts were deposed to by the surgeon:—The child was full-grown and was born alive: this was inferred from the lungs being completely inflated. A ligature was found on the neck,—it had been passed round twice,—was very tight, and fastened in a knot; it had caused two deep indentations. The vessels of the scalp and brain were distended with blood, but there were no marks of external violence. Death was caused by strangulation. The judge left it to the jury to say, whether they were satisfied that the child was wholly born into the world alive; and if so, whether the prisoner had knowingly and wilfully destroyed it after it was born. The prisoner was acquitted.

Constriction without ecchymosis—It may be an important question whether, in these instances, the absence of any mark or discoloration of the skin by the ligature should be taken as evidence of the means of constriction not having been applied during life. What we are entitled to say from observed facts is, that ecchymosis from the ligature is not a necessary consequence of
CONSTRUCTION OF THE NECK WITHOUT ECCHYMOSES. 525

Constriction, either in a living or dead child:—although we might expect that there would be few cases of child-murder in which, when strangulation was resorted to, there would not be some ecchymosed mark or discoloration, chiefly on the presumption that great force is suddenly applied. Besides, it is not improbable that a slighter force would cause ecchymosis on the skin of a new-born infant than would be required to produce such an effect on that of the adult. When there is no mark from a ligature, an attempt may be made to show that death could not have been caused by strangulation, as in the following case (the Queen v. Hagg), which was tried at the Carlisle Summer Assizes in 1841:—

The medical evidence was to this effect. The deceased child was discovered with a tape tied tightly round its neck. It was fullgrown and healthy, and had been born alive, as respiration had been fully established. The lungs filled the chest, floated on water, and creptitated when pressed. From the livid appearance of the face and neck, the congested state of the brain and effusion of blood on the surface, combined with the ligature round the neck, the witnesses were of opinion that the child had died from strangulation. On cross-examination, they said that a child may breathe when partially born. The floating of the lungs in water is of itself an uncertain test, if the body is at all decomposed. With other tests it affords a proof of a child having been born alive. One witness said the ligature had produced no mark or discoloration on the neck, while others said it was perceptible. The inference is, that the mark could not have been very apparent, or there would have been no discrepancy on this point. It was very ingeniously urged in the defence that the child could not have died from strangulation, because a tape tied so tightly round a child's neck as to cause death in this way, would necessarily leave a discoloration of which no person could have any doubt. The prisoners were convicted. Had the defence been, as in the former cases, that there was no proof whether the ligature had been applied before or after entire birth, or the establishment of an independent existence in the child, the result might have been different. From the cross-examination it will be seen how certain stock-objections to the hydrostatic test are ingeniously made to affect medical evidence. An answer to a general question is rendered applicable to a particular case. A witness admits on a trial that the lungs may float from putrefaction or artificial inflation: in short, from other causes than respiration. If this answer be not qualified, an impression is immediately conveyed to the Court, and not always removed by a re-examination, that some of these causes may have given rise to the floating of the lungs in this particular instance,—when in fact there may not have been the least trace of putrefaction, nor the least ground for suspecting that artificial inflation had been practised. As contrasts to this case, see report of a case which
occurred to Mr. Coales (G. H. Rep., 1842); and another by Lt. Scott (Ed. Med. and Surg. J. xxvi. 62).

8. Poisoning.—This is placed among the probable means of perpetrating child-murder, but we rarely hear of new-born children being thus destroyed. The earliest age at which I have known a trial to take place for the murder of a child by poison, was two months. (R. v. South, Norf., Aut. Circ., 1834.) A quantity of arsenic was given to an infant, and it died in three hours and a quarter after the administration of the poison. At this age, the case can scarcely be called one of infanticide, in its medico-legal signification; because all that it would be necessary to prove would be the cause of death,—the question of life or live birth would not require to be entered into. If, in a case of child-murder, death from poison should be suspected, it must be sought for in the usual way. Some cases have occurred, in which children have been wilfully destroyed a week or two after birth, by the administration of opium or excessive doses of purgative medicine. Oil of vitriol has been also used.

Examination of the mother.—The duties of a medical practitioner, so far as they relate to the mother of the child, generally the accused party, are slight. He may be required to prove, by an examination made under an order from proper authority, whether she has or has not been recently delivered of a child, and to state the probable period at which the delivery took place. (See post, Delivery, p. 551.) This examination may be necessary in order to connect her delivery with the period which may have elapsed since the birth and death of the child. Unless the examination of a female be made within twelve or fifteen days, no satisfactory evidence of delivery can in general be obtained. It has happened, on more than one occasion, that medical men have assumed to themselves the right of enforcing an examination of a suspected female, and, by threats or otherwise, have compelled her to undergo this. Such a course of conduct is in the highest degree indecent and improper:—if a female willingly consent to an examination, or an order be obtained from a magistrate or other official person, the case is different. In taking this authority upon himself, a medical practitioner is forcibly compelling an accused party to produce positive proof of her guilt,—a principle which is entirely opposed to the spirit and practice of English jurisprudence.

Conclusions.—The following conclusions may be drawn from the preceding remarks:—

1. That congestion of the face and head, in a new-born child, is not a proof of death from strangulation.
2. That strangulation can only take place in children which have breathed,
3. That a child may be strangled during birth by the accidental twisting of the umbilical cord round its neck.
4. That the umbilical cord may produce a livid or ecchymosed depression on the neck, like any other ligature.
5. That marks on the neck, arising from accidental causes, may resemble those which arise from strangulation.
6. That the effect of constriction on the neck, either by the umbilical cord or any other ligature, is the same if the child be living, whether it has or has not breathed.
7. That the effect is the same whether the child has been partially or entirely born.
8. That the effect of a ligature on the neck of a living child is the same, whether the umbilical cord has or has not been severed.
9. That a new-born child may die from strangulation, without this being necessarily indicated by ecchymosis on the neck. This depends on the nature of the ligature, and the amount of force used.

Summary. Frequent acquittals, in spite of medical evidence of criminality.—From the foregoing considerations it will be seen, that the two great points to be established by medical evidence, in a case of child-murder, are, — 1st, that a child was entirely born living when the alleged violence was applied to it; and, 2d, that its death was due to that violence, and to no other cause whatever. The leniency with which these cases are regarded by the law, and the extreme rigour with which the medical evidence of live birth, as well as of the cause of death, is treated, must show that they who consider that the use of the hydrostatic test can ever lead to the conviction of an innocent woman, have taken a very limited and incorrect view of the subject. The question of murder rests here, as in all other cases, upon clear and undoubted proof of the cause of death; —and more than this, it must be shown that the violence was criminal, and not by any possibility accidental. Then it should be proved that this violence, if criminal, must have been applied to the body of a child at a particular period — i.e. after entire birth; a case which, from what has already been stated, can rarely admit of clear medical proof. If strangulation, for example, be rendered probable from the facts, the woman cannot be convicted unless proof be afforded, 1st, that the child was strangled after its entire body was born; — and 2d, that she could not possibly have produced the marks of strangulation in her convulsive or half-conscious attempts at self-delivery. Medical evidence can rarely be in a condition to establish either of these points, and the assumptions will therefore be, as in the numerous cases already reported, in favour of the prisoner. A serious question will probably here suggest itself, from the number of impossible medical proofs, so to term them, which the law requires in these cases, namely — How can a con-
viction for child-murder ever take place when there are no witnesses to the crime? The answer is, that these dif-
makes may not be raised in the prisoner’s favour; but this of course is matter of accident. On most charges of infanticide, if the counsel for the defence insisted upon distinct medical proof of the child having been entirely born alive, when the violence was done to it; or that respiration, if clearly established by evidence, took place, not during labour, but after complete birth, or after the child had acquired an independent circulation;—neither of these proofs could be possibly afforded, and the case, so far as medical evidence was concerned, would fall to the ground. That this is not an exaggerated view of the subject, will be evident from a case tried at the Lancaster Lent Assizes, 1846 (Reg. v. Hacking). A female servant was charged with the murder of her infant child. The evidence went to prove that she had attempted to conceal her pregnancy. It was ascertained that she had been delivered of a child, and the medical evidence was to the effect, that its throat had been cut by some thin-bladed sharp instrument—a portion of the gullet and wind-pipe having been cut away. The prisoner stated that the child was born dead, and confessed that she had, as she believed, cut its throat with a pen-knife, which she had afterwards wiped and put away. The weapon was found in her pocket. The medical witness deposed, that the child had certainly breathed, and he was inclined to think that it had been born alive. He admitted that a child may breathe when partially born, and die before it is wholly born; also, that the appearance of the wound, whether inflicted before or immediately after death, would be very similar; and it was impossible, from the examination of it, to say whether the child had been partially or wholly born at the time of its infliction. The counsel for the prisoner contended that no evidence had been adduced which could satisfy the jury that the child had been fully born alive;—a circumstance without which the charge must fail to the ground. The jury acquitted the prisoner of the murder. (Med. Gaz. xxxvii. 382.)

In examining this case, it may be observed, that such a wound with a pen-knife was hardly likely to have been inflicted on the child by any accident, or for the purpose of aiding its expulsion during delivery. As the child had breathed, it is absurd to suppose that the woman waited until it had died from some other cause, of which there was no appearance; and that after death, without any conceivable motive, she cut out a portion of its throat. So far as the report goes, the acquittal appears to have depended on the allegation that the child was destroyed before it was wholly born; and although it had breathed, there was no want of evidence to show that this breathing had continued after it was entirely in the world. (See also another case in the same vol., p. 1007; and Prov. Med. Journ., April 2, 1851, p. 182.)
The frequent acquittals which take place on charges of child-murder, in spite of strong evidence of criminality, most probably depend on the fact, that there are many extenuating circumstances in a prisoner's favour. She may be young, unfortunate, friendless, and perhaps tempted by a seducer, or by utter destitution, to the perpetration of the crime. According to the present state of our law, the jury have no alternative but to convict her of a capital offence, or acquit her of the charge of murder, and find her guilty of the concealment of birth, the extreme punishment for which is two years' imprisonment. This is substantially the punishment at present inflicted for the crime of infanticide in this country; for it is not to be concealed that, medically speaking, these technical points relative to "live birth," to "entire birth," or to an "independent circulation in the child," or lastly, "concealed birth," are only so many ingenious legal means for evading convictions on a capital charge. Whatever doubt may exist according to the forms and principles of law, there can be no doubt, medically, that living children are often criminally destroyed, and that the law, from the peculiar nature of the proof required, as well as from the severity of the punishment attached in all cases to the crime, cannot reach the perpetrators. In many of these cases the punishment of death would be as much too severe, as the punishment of two years' imprisonment for "concealed birth" is too slight; and with a full contemplation of this difficulty, the Civil Code of France (Art. 319) wisely permits the Court, on proof of extenuating circumstances, to mitigate the punishment. Some such provision is required in our law; and the unnecessary perplexities which are now thrown on medical evidence, as well as the conflicting opinions on what is live birth and what is not, would then disappear. A change of this kind might undoubtedly be made, without prejudice to the accused, or interference with the course of justice. A writer in the Legal Examiner (Sept. 11, 1852, p. 555) has suggested that a special Act of Parliament should be passed to render proof of "entire birth" unnecessary, and that there should be at the same time some mitigation of the punishment. A modification of this kind appears to be necessary, unless we are prepared to admit that the destruction of a living and breathing child during the act of birth is not a crime.

It is a question which it would be here out of place to discuss, whether a verdict of manslaughter might not be proper on many of these occasions; for to say that the whole offence consists in concealing the birth of a still-born child, is virtually to disbelieve and reject the clear and satisfactory medical evidence often adduced. A verdict of manslaughter would not, however, cover those numerous cases in which it is supposed that the child had only lived to expire during the act of birth, and not afterwards; and yet in a recent case (Reg. v. Tomney, Warwick Lent Assizes,
1854), tried before Coleridge J., in which a medical witness declined to say positively that a child was born alive and had breathed after birth, the jury convicted the prisoner of manslaughter. Respiration had been established, but it was admitted by the witness that this might have occurred during birth. There was a cut on the right side of the neck of the child, and a circular wound in the windpipe. The jury considered, notwithstanding the medical doubt, that the child had really come into the world alive. At the same time, they appear to have thought that the wounds on the neck were caused during attempts at self-delivery, and had not been inflicted with the intention of murdering the child. Dr Christison, in commenting upon the frequent acquittals on the capital charge, and convictions only on a minor offence, which cannot always be proved, attributes it to a feeling sometimes entertained in the present day, that the killing of a newborn child, when perpetrated under the impulse of injured honour and the fear of disgrace, should not be classed with the other varieties of murder. (See Ed. M. and S. J. xxvi. 76.) There can, I think, be no doubt that this is the true explanation. (See also case by Mr. Coules, Guy's Hospital Reports, April 1842.)

It may be mentioned, in concluding this subject, as the point has given rise to a trial for malapraction, that if injuries should be criminally inflicted on a child during birth, and the child be born alive and afterwards die from the injuries so caused, the case would be murder or manslaughter, according to the circumstances. The following instance is reported by Chitty (Med. Jur. 416; also Archbold, 345):—A man of the name of Senior, who, it appears, was an unlicensed medical practitioner, was tried, in 1839, for the manslaughter of an infant, by injuries inflicted on it at its birth. The prisoner practised midwifery, and was called to attend the prosecutrix, who was taken in labour. The evidence showed, that when the head of the child presented, the prisoner, by some mismanagement, fractured, and otherwise so injured the cranium, that it died immediately after it was born. It was argued in defence, that as the child was not born (in ventre sa mère) at the time the wounds and injuries were inflicted, the prisoner could not be guilty of manslaughter. The judge, however, held that as the child was born alive and had died, the case might be one of manslaughter. This opinion was afterwards confirmed by the other judges, and the prisoner was convicted and sentenced to imprisonment. From the decision in this case, it will be seen that the law makes the question of criminality to depend upon the period at which the injuries prove fatal, and not upon the time at which they are inflicted on the body of a child. The decision appears to depend on this principle of the criminal law, that the person killed must be a reasonable creature in being, and under the king's peace;—therefore to kill a child in its mother's womb (or during birth) is no murder. (Archbold, 345.)
CONFLICTING MEDICAL AND LEGAL VIEWS.

The child, unless entirely born alive, does not come under the description above given. It is under these circumstances medically but not legally a living child. Admitting the wisdom of adopting some fixed rule of this kind in a legal view, it is undoubtedly proper that the lives of children during the act of birth should be protected: — at any rate, that their destruction should not be treated, as it now appears to be, with perfect impunity.

If a child be born alive, as a result of criminal abortion, and die, not from any violence applied to its body, but as an effect of its being immature, this will be sufficient to render the party causing the abortion indictable for murder.

It is difficult to determine the number of cases of infanticide which take place annually in this country; but in France, where criminal statistics are more closely attended to, there were, in 1838, one hundred and twenty-nine cases; and in 1841, one hundred and forty-seven cases. (See Annales d’Hygiène, Oct. 1840.)
PREGNANCY.

CHAPTER XLVII.

Pregnancy. Legal relations. — The subject of pregnancy, in so far as the proofs of this condition in the living female are concerned, rarely demands the attention of a medical jurist. If we except the very few instances in which a magistrate requires an opinion from a medical man respecting the pregnancy of a pauper female brought before him, there are only two cases in the English law in which pregnancy requires to be verified; and these so seldom present themselves, that the questions connected with the pregnant state rather belong to the science than the practice of medical jurisprudence.

Signs of pregnancy.

Suppression of the menses. — It is well known that in the greater number of healthy females, so soon as conception has taken place, this secretion is arrested. But there are certain abnormal conditions, which must not be overlooked. There are some cases recorded which show that women, in whom the menses have never appeared, may become pregnant. This, however, is allowed by all accoucheurs to be rare; and when it occurs, which we may readily learn from the account of the female, it will be necessary to search for other signs in order to determine the question of
pregnancy. Irregularity as to the period at which the function takes place is very common among females. This irregularity may depend either upon the age of the person, or upon disease, either of which causes it will not be difficult to recognize. It is well known that there are numerous disorders of the uterus under which, irrespective of pregnancy, the menses may become suppressed. The continuance of the menstrual discharge, when once set up, is not a necessary condition for pregnancy. Dr. Murphy has reported the case of a woman who for sixteen years went on bearing children, eight in number, without having had during that period any appearance of the menses. The late Dr. Reid, who quotes this case, mentions five instances that fell within his own knowledge in which females became pregnant notwithstanding a long previous cessation of the discharge (Lancet, Sept. 10, 1853, p. 236). The absence of the menses as a consequence of pregnancy is generally indicated by the good health which a female enjoys; and, although disease may coincide with pregnancy, yet a careful practitioner will be able to estimate from the symptoms to which cause the suppression is due. On the other hand, a discharge perfectly analogous to the menstrual, sometimes manifests itself, not merely for several periods in a pregnant woman, but during the whole course of pregnancy. (Dr. Murphy’s Obstetric Report, 1844, p. 9; also, Henke, Zeitschrift der S. A., 1844, 265.) Mr. Whitehead has collected seven well-marked cases of menstruation during pregnancy. (On Abortion, 218.) These facts show that we must be cautious in our opinion; and not declare that, because a discharge continues, pregnancy cannot possibly exist, or, because it is suppressed, a female must be pregnant.

Feigned menstruation. — The menses may be really suppressed; but if there be any strong motive for the concealment of her condition, a female may feign menstruation. Dr. Montgomery detected a case of this kind, by the examination of the areolae of the breasts. The woman had stained her linen with blood, in order to make it appear that the menses continued; but she subsequently admitted that this was an imposition. It has been stated that there are differences between menstrual and ordinary blood, but there are no certain chemical means of distinguishing them. (See ante, p. 316.)

Prominence of the abdomen. — A gradual and progressive enlargement of the abdomen is a well-marked character of pregnancy. The skin becomes stretched, and the navel almost obliterated. The enlargement in general begins to be obvious about the third month, although there are some females of peculiar organization, in whom the enlargement may not become perceptible until the fifth or sixth month, or even later; still it may be detected on examination. In fact, this sign can never be absent in pregnancy, although it may not be so apparent in.
some females as it is in others. The objection which exists to
it is, that numerous morbid causes may give rise to prominence
of the abdomen. This is undoubtedly the fact,—as we have
occasion to witness in the various kinds of dropsy, or in sup-
pressed menstruation,—diseases which, in several instances,
have been mistaken for pregnancy by eminent practitioners.
On the other hand, instances are not wanting, in which, owing
to the persistence of menstruation, and the absence of quickening,
the gravid uterus has been actually tapped, by mistake, for an
ovarian tumour: the operation being speedily followed by the
birth of a full-grown child! (see Whitehead on Abortion, p.
186); but the history of a case will in general enable a prac-
titioner to form an opinion. A case of suppressed menstruation
strongly simulating pregnancy, is reported by Dr. Rüttel. (Henke,
Zeitschrift, 1844, 249.) The enlargement may be owing to
disease, 1, when it has been observed by the female for a time
longer than the whole period of gestation, 2, when it has been
accompanied by a generally diseased condition of the system,
and, 3, when there is an absence of the other symptoms of preg-
nancy. The most embarrassing cases are unquestionably those
in which abdominal disease coexists with pregnancy. Here
time alone can solve the question, and a medical jurist should
give the benefit of his doubt to the side of chastity, mercy, and
humanity. (On an important case in which an abdominal
tumour was mistaken for pregnancy, see Lancet, Oct. 16, 1847,
p. 408.) While the abdomen enlarges from pregnancy, the
margins of the abdominal muscles become more clearly defined.
The navel is less depressed, and gradually acquires the level of the
surrounding skin. As pregnancy advances, it becomes more
prominent, and in the last month it assumes the character of a
tumour, instead of a depression. (Whitehead, loc. cit. 209.)

A change in the breasts.—These organs in a pregnant female
are full and prominent, and the areola around the nipples under-
go changes which Dr. Montgomery and others regard as highly
characteristic of the pregnant state. A mere fulness or pain in
the breasts, and even in some rare instances the secretion of milk,
may arise from other causes than pregnancy. Severe uterine or
ovarian irritation may cause the breasts to become painful and
swollen. The fulness of the breasts from pregnancy is not com-
monly observable until about the second or third month; and
with regard to the secretion of milk, in non-pregnant females,
the few rare cases of its occurrence on record show that it takes
place under circumstances which cannot well be mistaken for the
pregnant condition. (See Henke, Zeitschrift der S. A. 1844,
269.) The areola is generally observed, during pregnancy, to
become considerably darker in colour, and larger in diameter.
The skin of which the areola is formed becomes soft, moist, and
slightly tumid. The little glandular follicles about it are promi-
PREGNANCY. QUICKENING.

...and often bedewed with a secretion: among these changes that of colour has been the most attended to. They are commonly well marked in from the second to the fourth month of pregnancy: the intensity of colour being the last condition of the areola to appear. The prominence of the glandular follicles does not always exist in pregnancy, and the areola may become large and dark-coloured from other causes: consequently, these signs are only to be looked upon as corroborative. In females of dark complexion, the areolas are dark, irrespective of pregnancy; and in some cases of advanced pregnancy these changes in the areolas are entirely absent. (Edin. Month. Jour., March 1848, 693.) Dr. Montgomery has described, as a sign of pregnancy, the existence of a brown line extending from the pubes to the umbilicus, especially in females of dark complexion, and a dark-coloured but not raised areola of about a quarter of an inch in breadth, around the navel.

Quickening.—The signs above given are applicable to the early as well as to the late stages of utero-gestation; but that which we have here to consider is one which is rarely manifested until about the fourth or fifth month. Quickening is the name applied to peculiar sensations experienced by a female about this stage of pregnancy. The symptoms are popularly ascribed to the first perception of the movements of the fetus, which occur when the uterus begins to rise out of the pelvis; and to these movements, as well as probably to a change of position in the uterus, the sensation is perhaps really due. The movements of the fetus are perceptible to the mother before they are made evident by an external examination. The term is derived from the old Saxon word “quick,” signifying living, as, at the time when medicine was in its infancy, it was considered that the fetus only received vitality when the mother experienced the sensation of its motions! On the occurrence of quickening, there is generally great disturbance of the system; indicated by syncope, nausea, and other distressing symptoms. After a short time the female recovers; and if sickness has hitherto attended the pregnant state, it has been frequently observed to disappear when the period of quickening has passed.

No evidence but that of the female can satisfactorily establish the fact of quickening, and this it is necessary to bear in mind; since, in some cases in which pregnancy is an object of medico-legal importance, proof of quickening may be demanded by the law. Dr. Reid remarks (Lancet, Sept. 10, 1853, p. 237) with respect to this sign, that very few women can tell the exact day on which they first feel it; and a large proportion cannot place it within a range of fourteen days, which is of little assistance in the calculation of the probable date of delivery. Women who profess to be most exact in noting the period of quickening, differ from each other as to
the time. There is much self-deception as to this symptom. The discovery of the movements of a child by an examiner is really a proof that the usual period of quickening is past, but their non-discovery, at the time of examination, is no proof whatever that the woman has not quickened: since the movements are by no means constant, and may be accidentally suspended even at several successive examinations. Besides, cases every now and then occur, in which well-formed, healthy females do not experience the sensation of quickening during the whole course of pregnancy; and what is of more importance, the movements of the child may be at no time perceptible to the examiner. The uncertainty of quickening, as a sign of pregnancy, is too well known to require more than advertizing to. Females have been known to mistake other sensations for it, and in the end it has been proved that they were not pregnant. A woman may also declare that she has felt quickening when she has not: and unless the movements of the child be perceived by the examiner at the time, how is he to disprove her statement? Quickening, then (so far as it concerns the statement of the female), cannot be relied on as a proof of pregnancy; but if the movements of the child can be felt by the examiner through the abdomen, this is clear evidence, not only of the woman being pregnant, but of her having passed the period of quickening.

We may next consider the period of pregnancy at which this symptom ordinarily occurs. Our law seems to infer, that it is a constant, uniform, and well-marked distinction of the pregnant state; and in some instances it insists upon proof accordingly. Taking the general experience of accoucheurs, quickening happens from the tenth to the twenty-fifth week of pregnancy; but the greater number of instances occur between the twelfth and sixteenth week; — or between the fourteenth and eighteenth week after the last menstruation. The late Dr. Reid considered it to denote about the sixteenth, seventeenth, or eighteenth week of pregnancy. The date corresponds to the termination of the fourth calendar month. One of his patients did not feel this symptom until the seventh calendar month (Lancet, September 10, 1853). It is a popular opinion that quickening takes place exactly at the end of four calendar months and a half; but it mostly occurs two or three weeks earlier than this period. Many females estimate that they are four months advanced in pregnancy when they quicken; but this mode of calculation is open to numerous fallacies. Dr. Rodrigue knew a lady who invariably quickened at two months, and went full seven months after, with all her children,—five in number. (Amer. Jour. Med. Sci., Oct. 1845, p. 339.)

From these observations, it will be seen that an examiner may sometimes detect the movements of the child about the third or fourth month,—at others not until the fifth or sixth; — and in other
instances not at all, throughout pregnancy. Even in those cases in which the movements of the child have indisputably existed, they are not always to be perceived; hence several examinations should be resorted to, before any opinion can be fairly expressed from their absence. In making these examinations, the diagnosis is often facilitated by previously immersing the hand in cold water, and then suddenly applying it to the abdomen. When the movements of the child are distinctly perceived through the parietes of the abdomen, they constitute a certain sign of pregnancy; but their non-discovery at a particular time is no proof that the female is not pregnant. The jury of matrons probably trust to this sign: hence their verdicts commonly turn out to be erroneous. There is another source of fallacy which may present itself when an artful woman is desirous of making it appear that she is pregnant,—namely, that a woman may simulate the movements of a child by a peculiar action of the abdominal muscles. Medical practitioners of repute have been deceived for a time by this artifice: but this occurred before the discovery of chloroform or the stethoscope.

Sounds of the fetal heart—Another sign is that which is derived from auscultation. By the application of the ear or a stethoscope to the abdomen, at or about the fifth month of pregnancy, rarely earlier, the pulsations of the fetal heart may be recognised and counted. These pulsations are not synchronous with those in the arteries of the mother; they are much more rapid, and thus it is impossible to mistake them. Their frequency, according to Dr. Hope, is in an inverse ratio to the stage of gestation, being 160 at the fifth, and 120 at the ninth month. This sign, when present (like the movements of the child), not only establishes the fact of pregnancy beyond all dispute, but shows that the child is living. The sound of the fetal heart is, however, not always perceptible: when the child is dead, of course it will not be met with: but its absence is no proof of the death of the child, because the hearing of the pulsations by an examiner will depend very much upon the position of the body, the quantity of liquor amnii, and other circumstances. Thus it may be distinctly heard at one time, and not at another. It may be absent for a week or fortnight; and then will reappear:—so that, although its presence affords the strongest affirmative evidence, its absence furnishes very uncertain negative evidence; and several examinations should be made in the latter case, before an opinion is formed. The earliest time at which the pulsations may be heard has been stated to be about the fifth month: but they will be best heard between the sixth and eighth. The reason why the sound is not always perceived, is owing not only to changes in the position of the child, but to the vibrations having to traverse the liquor amnii and the soft parietes of the abdomen. The point of the abdomen where the sound can be best heard is in the
centre of a line drawn from the umbilicus to the anterior inferior spinous process of the ilium on either side,—perhaps most commonly on the right. When clearly detected, it is an unequivocal sign of the pregnant state. Besides the sound of the foetal heart, auscultation has led to the discovery of what is called the placental murmur. This sound is more likely to create fallacy than that of the foetal heart.

**Kiester in the urine.**—A substance called Kiesterin has been found in the urine of pregnant females. It appears as a fatty iridescent pellicle on the surface of the urine about twenty-four hours after it has been voided. There are various opinions concerning the nature of this substance, some regarding it as a mixture of casein and oil with earthy phosphates (Dr. Bird, G. E. Rep., April 1840, p. 26), and others as a modification of albumen (L’Héritier, Chimie Pathologique, 483). From the researches of Dr. Möller, its presence in the urine is subject to so much uncertainty, that it is wholly unfit to serve in medical jurisprudence as a diagnostic character of pregnancy (Casper’s Woehnschrift, i. 1845, S. 21). Dr. Mierschick has arrived at the same conclusions (Med. Gaz. xxxix. 264). Mr. Kane obtained kiesterin in equally great quantity from the urine of a virgin aged fourteen, and that of a woman who had nursed for two months. (Whitehead on Abortion, 231). Dr. Golding, however, entertains a high opinion of its value as a sign of pregnancy in its earlier stages when the other signs are obscure. According to this gentleman, it is present in the urine at all periods of pregnancy; it is identical with milk in a crude form, and is to be regarded as a secretion of the mammary glands (Obstetric Record, 3, p. 45). Dr. Rees has detected in it milk-globules, and considers it to be caseous matter altered by passing through the kidney (Anal. of Blood and Urine, 217).

In reference to the above signs, it may be observed, that if the motions of the child or sounds of the heart be perceptible, no other evidence of pregnancy need be sought for. The mere suppression of the menses, prominence of the abdomen, and fulness of the breasts, cannot alone establish the fact; but, unless the morbid causes of these abnormal states of the system be clearly and satisfactorily obvious to the examiner, it is a fair presumption that the female is pregnant. In any case in which a doubt exists, we should require sufficient time for a clear opinion.

**Changes in the mouth and neck of the uterus**—The signs hitherto mentioned are chiefly relied on in medical practice; but it must be remembered that no case can possibly occur in civil or criminal jurisprudence, in which it will not be in the power of a medical witness to make an examination of the female. He may then form a safe judgment from the changes which take place in the neck of the uterus, and from the sensation imparted to the finger by the presence of a rounded body (like the foetus) floating
in a liquid, when an impulse is given to the uterus from below. Up to the fifth or sixth month of pregnancy, the neck of the uterus may be commonly felt projecting into the vagina; it is of its usual length, hard and firm,—after that period the uterus rises into the pelvis, and the neck is spread out, shorter and softer, the aperture increasing in size and becoming rounder. Towards the end of gestation, the neck of the uterus appears to be lost, becoming like a thin membrane, and sometimes no aperture can be felt.

A well-marked test of pregnancy is the motion perceptible to the finger on giving a sudden impulse to the neck of the uterus. Capuron calls this the touchstone in the distinction of the pregnant state;—without it, he considers a medical jurist may be easily deceived. To this passive motion of the child, the name of ballottement is given. It cannot be easily determined before the fifth or sixth month; but after the latter period, especially as pregnancy becomes advanced, it is always available. In the French schools, the method of applying the toucher and ballottement to pregnant females is systematically taught, and by a little practice it may be easily acquired.

As most of these signs refer to an advanced stage, a witness may be asked what are the unequivocal indications of pregnancy before the fifth and sixth month? The answer to this question is of little moment to the medical jurist, since he is rarely required to give an opinion under these circumstances. In all legal cases, when pregnancy is alleged or suspected, it is the practice for a judge or magistrate, on a representation being made by the medical witness, to postpone the decision one, two, or three months, according to the time required for obtaining certain evidence. This evidence will consist in plainly distinguishing a rounded body floating freely in the uterus,—the movements of a fetus, and,—the sounds of the fetal heart. The most experienced men agree, that before the sixth month, the changes in the cervix and os uteri are of themselves too uncertain to enable an examiner to form a safe opinion; and à fortiori it is impossible to trust to external signs. Mr. Whitehead dissents from this view, and considers that a specular examination of the mouth of the uterus is not only more satisfactory than any other mode of exploration, but that it will enable a person to determine with certainty the existence of pregnancy during its earlier stages—from a few days after conception to the middle or end of the fourth month, when auscultation first becomes available. In the fourth week the labia of the mouth of the uterus at the centre of their margins are permanently separated to the extent of one or two lines; and the os tinece (the aperture) itself, which was before a mere chink with parallel boundaries, forms an elliptical, or sometimes rounded aperture, which is occupied by a deposit of transparent, gelatinous mucus. At six or eight weeks it is decidedly oval
or irregularly circular, with a puckered or indented boundary having a relaxed and lobulated character. The whole circumference of the neck is enlarged, and the commissures or angles of the os intumae are obliterated. The os continues of this irregular form throughout the whole period of gestation; but from the time of quickening to the end of the seventh month the progressive changes are not so marked as to form a guide for determining the period of pregnancy. (On Abortion, 204.) This condition of the mouth of the uterus must not be confounded with its menstrual state in the early stages, nor with a diseased state in the latter stage of gestation.

Feigned pregnancy.—Pregnancy is sometimes feigned or simulated for the purpose of extorting charity, of obtaining a settlement in a parish, or of compelling marriage; but it is scarcely necessary to observe that an imposter may be easily detected by a well-informed practitioner, since the woman always feigns an advanced state of pregnancy. Although she may state that she has some of the symptoms depending upon pregnancy (and, unless she has already borne children, she will not be able to sustain a cross-examination even respecting these), yet it is not possible for her to simulate without detection a distension of the abdomen or the state of the breasts. If she submit to an examination, the imposition must be detected: if she do not, the inference will be that she is an imposter. Females have been known to possess the power of giving apparent prominence to the abdomen, and even of simulating the movements of the child by the aid of the abdominal muscles (ante, p. 537). By placing them under the influence of chloroform, the abdomen at once collapses, and the imposture is detected. These cases of spurious pregnancy are sometimes met with in hysterical females. (See case by Dr. Simpson, Edinburgh Monthly Journal, 1854, vol. ix. p. 473. See also Lancet, April 14, 1855, p. 381; April 28, 1855, p. 429; and May 26, 1855, p. 533.) Pregnancy may be feigned by a female in order to avoid being sent by a magistrate's order to a distant parish, or to escape the punishment of hard labour, to which she may have been sentenced. If in the latter case the slightest doubt should exist whether the female be really pregnant or not, an affirmative opinion should be given, at least for a time, since very great and even irreparable mischief might result by taking an opposite course.

In civil cases of feigned pregnancy, an examination should always be insisted on, or the reputation of a practitioner may suffer by his giving a hasty opinion on the subject. In this respect the case of Devonald v. Hope, Q. B., December 1838, is of some interest. A medical man having given an opinion that a female patient was pregnant, subsequently brought an action against her for medical attendance. It turned out, however, that she was not pregnant, and that there were no satisfactory
medical grounds upon which his opinion was issued. The plaintiff complained of having been deceived by the female as to her condition; but it is obviously in the power of every medical man to prevent such a deception being practised on him. An external examination only will not suffice either to afford or negative the allegation of pregnancy, except when it is known to be far advanced. For a singular case in which, on a charge of assault, evidence of this kind was tendered, see Med. Gaz. xxxv, p. 1083, 1169. (On the infamy of the signs of pregnancy, and the simulation of this state, see a paper by M. Tardeau, Ann. d'Hg. 1845, t. p. 429; also 1846, t. 62.)

De ventre inspiciendo.—One of the cases in the English law, in which pregnancy requires to be verified is of a civil nature. It is in relation to the Chancery writ " de ventre inspicendo." A woman may assert that she is pregnant at the time of her husband's death, and the heir-at-law may sue out a writ to require some proof of her alleged pregnancy, as the right to the estate of which the husband died possessed may be materially affected by the result. Until within a recent period, the decision of the question of pregnancy was left to twelve matrons and twelve respectable men, according to the strict terms of the ancient writ; but in some late cases it has been considered advisable to depart from this absurd custom, and to place the decision in the hands of medical practitioners.

In May, 1835, a gentleman named Fox died, leaving a widow, to whom he had not been married more than six weeks. By his will, made some months before his death, he left the great bulk of his property to the use of Ann Bakewell, spinster, for the term of her natural life, so long as she remained sole and unmarried; and after her decease or marriage, to one John Marston. Soon after the making of the will, this Ann Bakewell became the wife, and subsequently the widow of Mr. Fox. Notwithstanding that she had married the testator himself, the plaintiff Marston claimed the property from the widow, on the ground of her having infringed the terms of the will by her marriage with the testator! She pleaded pregnancy, and in August, 1835, the writ " de ventre inspiciendo" was sued out of Chancery by Marston. Some discussion took place in Court on the question whether the writ should be issued in its original indecent or not: i.e. whether the female should undergo examination by the sheriff, assisted by twelve matrons and twelve respectable men! The widow petitioned the Court not to issue the writ; and put in an affidavit from her ordinary medical attendant, to the effect that she was pregnant and too weak to undergo the proposed examination. Ultimately it was decided that two matrons, with a medical man on each side, should visit Mrs. Fox once a fortnight until her delivery. There was no doubt of her pregnancy, and she was delivered at the due time, to the great disappointment of the
that in the present day any attempt at the feudal customs of a rude and barbarous nation of questions which belong to the state of medical science.

Plea of pregnancy in bar of execution, which pregnancy requires to be verified by declaration to criminal jurisprudence. If a woman who has been convicted, she may plead pregnancy, and the judge will then direct a jury of twelve men of the "cumstantibus," to be empanelled, and the jury will decide of the law, "whether the prisoner be pregnant or not." If they find her quick with child, sentence will take effect. It is the principle by which a pregnant woman, just before her delivery, there are two serious objections to the common law, whereby it is made applicable to the civilized country, society has a right to insist on the fact of a woman having been pregnant, and the pregnant state has been known to occur as late as the sixth month: some have even been quickened as late as the seventh month without observing the signs of pregnancy, and in case of a confession, the only possible way in which it may be proved,
a jury of matrons; and they, after a form of examination had been gone through, brought in a verdict of *not quick* with child. The woman would have been executed, had not several medical practitioners of Norwich represented to the judge, that the method taken to determine pregnancy and quickening was so unsatisfactory, that no reliance should be placed upon it. The prisoner was then examined by some medical men, and was found to have passed the usual period of quickening! The judge respited the prisoner, and the correctness of the medical opinion was confirmed by the female being delivered, within four months afterwards, of a healthy full-grown child. (See Med. Gaz. xii. 22, 585; *Rex v. Wright*, Norwich Lent Assizes, 1832.) In a case tried in March, 1838, a woman was convicted of murder, and pleaded pregnancy. A *medical* opinion was here required. The pregnancy, if it existed, had so little advanced, that the practitioner was unable to give a satisfactory report; and the judge respited the prisoner for a month, in order that the witness might have full opportunity to ascertain the fact. Still the jury of matrons is occasionally resorted to. Thus in the case of *Reg. v. Westwood* (Stafford Winter Assizes, 1843,) the matrons were summoned to examine a female capitally convicted, and they negatived the plea! It is not a little remarkable that, although in so many cases the matrons have given a wrong verdict, and that in no instance can they give a right one except as a matter of pure conjecture, the practice still continues. Thus this antiquated practice was again revived at the Central Criminal Court in 1847. (*Reg. v. Hunt*, September, 1847.) This woman was convicted of murder; she pleaded pregnancy, and the matrons were empennelled and directed to use "their best skill" to determine whether the prisoner "was big with a quick child or not." It was left to their option to have the assistance of a surgeon. In half an hour they returned a verdict "that she had not a living child within her." The law was directed to take its course; and the woman would have been executed, but for the interference of the Secretary of State. He directed that the prisoner should be examined by competent medical men, who ascertained that she was really pregnant, and had passed that stage at which quickening is most commonly perceived. She was therefore respited, and the error in the verdict of the matrons was clearly proved by the birth of a child on the 28th December!

The value of the opinion of a jury of matrons upon such matters, may be estimated from the following facts. The late Dr. Reid records the case of an expert midwife who, when examined in the celebrated Gardner Peerage cause, deposed "that she had herself once gone ten months with child,—that she was always right in her calculations—that she always fainted away at quickening, &c., so that she could never be deceived." Some
time after the trial she applied to Dr. Reid, convinced on such
grounds that she was seven months pregnant. But on exami-
nation, Dr. Reid found that there was no pregnancy at all!

There seems to be no uniform rule of practice in such cases.
In Reg. v. Featherston (Chester Assizes, 1854), prisoner was
convicted of the murder of her child, and a plea of pregnancy
was put in by her counsel. A jury of matrons, taken from women
present in Court, was empanelled and sworn to try whether she
was quick with child, &c. After an examination of the prisoner,
the jury by their forewoman said:—“The prisoner is not quick
with child: she is not in the family way.” In Reg. v. Weeks,
Exeter Lent Assizes, 1856, this plea was urged in stay of execu-
tion on a capital conviction for murder. A jury of matrons
was sworn in the usual way to inquire into the fact, and “two
doctors” were sworn to examine the prisoner and give evidence
before the jury of matrons. After a short time, they found that
the prisoner was pregnant, and sentence was respited until after
her delivery.

It is unnecessary in the present day to discuss the question,
whether, until the period of quickening, the child be or be not
“pars viscerum matris.” The vulgar opinion is, that the fetus
only receives life when the woman quickens: but the law should
not base its decisions in reference to capital punishment upon
vulgar opinions. As ovum, embryo, and fetus, the contents of
the uterus are as much endowed with special and independent
vitality in the earlier as in the later periods of gestation. It is,
then, absurd to fix upon an accidental and uncertain symptom,
occasionally felt by a pregnant female, as the point at which
clemency may be shown. The bare proof of pregnancy, as in the
law of France (Art. xxvii. of the Penal Code), should be sufficient
to authorize a suspension of the sentence. The doctrine of
quickening has been abandoned in relation to the law of
criminal abortion; and there is still greater reason for its im-
mediate abolition in reference to pregnant females capitaly
convicted.

This change would, however, be attended with but little
benefit if the decision of the question of pregnancy were still
to remain in the hands of “matrons.” The record of their
mistakes sufficiently establishes the correctness of this view: for
if they are unable to recognise the pregnant state at the fifth
month, and as experts are liable to be deceived about their own
condition, they cannot fail to be mistaken in their opinions at ear-
lier periods. It is, indeed, an extraordinary circumstance, that
when married women advanced in pregnancy are themselves con-
tinually deceived, and are obliged to consult medical men re-
specting their condition, they should be specially selected by the
law as the persons best qualified to pronounce an opinion upon
the pregnancy of a female, in a case involving the infliction of
CONCEALMENT OF PREGNANCY.

capital punishment. It would be considered inhumane to execute knowingly a pregnant woman, but the imputation of inhumanity is not the less deserved by a law which virtually leaves the issue in the hands of ignorant and incompetent persons. The Americans are certainly in advance of us in their legislation on this subject. Thus, by the revised statutes of New York, when pregnancy is pleaded in bar of execution, it is enacted that the sheriff shall summon a jury of six physicians, and shall give notice to the district attorney, who shall have power to subpoena witnesses.

These are, I believe, the only two cases in which pregnancy has any direct relation to medical jurisprudence; and it is remarkable, that with respect to them, the law of England has expressly provided that they should be left to the decision of non-medical persons! The following conclusions may therefore be drawn:—1. That the cases in which the signs of pregnancy become a subject of legal inquiry in England are rare:—2. That there is no case in English law, in which a medical man will not have an opportunity of performing an examination per vaginam:—3. That a medical opinion is never required by English law-authorities, until the pregnancy is so far advanced as to render its detection certain. Hence discussions concerning areola, the condition of the breasts, the presence of kieslein in the urine, &c., are in a practical point of view unnecessary to a medical jurist. By these remarks I do not intend to undervalue the importance of an accurate knowledge of the signs of pregnancy to a medical practitioner. Cases which may never come before a Court of Law will be referred to him, and the serious moral injury which he may inflict on an innocent female by an inaccurate diagnosis should make him scrupulously cautious in expressing an opinion. On this subject the reader may profitably consult a paper by Dr. Nelson (Lancet, Nov. 22, 1851, p. 485). On other occasions his own reputation may suffer by a mistake on this subject. A married lady in Scotland, who had not had a child for a long period, thought that she had become pregnant, and consulted the chief physician in the place, a man of skill and experience (now deceased). He saw this lady several times, and had every opportunity of examining her condition. He gave a very decided opinion that she was not pregnant. The lady, however, made her preparations, and one night, not long after the medical opinion had been formally given, the physician was sent for to aid in the delivery!

Concealment of pregnancy.—By the law of Scotland, if a woman conceals her pregnancy during the whole period thereof, and if the child of which she was pregnant be found dead, or is amissing, she is guilty of an offence, and is liable to prosecution. Evidence is sometimes given as to outward appearances indicative of pregnancy: but the main proof of a woman having
been pregnant, and that which is relied on for conviction, is clear and distinct evidence of the actual delivery of a child. This is generally furnished by medical witnesses. The Scotch law, by making the concealment of pregnancy, under the circumstances above-mentioned, an offence, proceeds on the principle that every pregnant female is bound to make preparations for the safe delivery of a child; and it is therefore assumed that if a child be born clandestinely without preparation, and is found dead or is missing, its death is owing to the want of such preparation.

Pregnancy in a state of unconsciousness.—It was formerly a question whether a woman could become pregnant without her knowledge. This may undoubtedly happen, when intercourse has taken place during profound sleep (lethargy), or when a female has been thrown into this state by narcotic drugs or vapours. But it is very difficult to admit that any woman should remain pregnant up to the time of her delivery, without being conscious of her condition, if the intercourse took place during the waking state. A woman endowed with ordinary intellect could not avoid suspecting her condition after the fourth or fifth month: and this alone would be sufficient to induce her to seek advice whereby the fact would become known to her. When a woman is impregnated in a lethargic state, it is very unlikely that she should go beyond the sixth month without being fully aware of her pregnancy, as a female with innocent motives would undoubtedly make some communication to her friends. Capuron mentions a case of this kind, in which the fact of pregnancy was first ascertained at the end of the fourth month, by the female having complained to one of her sisters of a strange sensation which she experienced in the lower part of her abdomen. (Méd. Lég. des Accouchemens, 86.) In a case related by Mr. Skey, a young female who had intercourse knowingly, was supposed not to have been aware of her pregnancy until the seventh month; but there is strong reason to believe that the woman was guilty of deception. (Med. Gaz. xxxix. p. 212.) There are generally, in these cases, strong motives for falsehood; hence such stories require close investigation before they are allowed to influence the opinion of a practitioner. A case occurred in September 1857, in which a woman, aged 22, described as modest and decorous in her behaviour, then advanced to the sixth month of pregnancy, asserted that she had not consciously had connection with any one, although she specified a date at which she remembered she had lost her consciousness—at which date intercourse might have been had! On being questioned, she denied that she had had at any time any soreness or pain in her private parts. Although there may be unconscious intercourse and pregnancy, it is not probable that in the case of a virgin there should be such intercourse without the
production of pain, soreness, or laceration; and those symptoms, if not perceived at the time, should be felt subsequently and create suspicion, if not actual knowledge, of what had happened. This rendered the account which she gave wholly improbable. The fact that she was able to fix a date for her unconsciousness, with an accuracy in accordance with her condition, was also a suspicious circumstance. It is quite possible that women who are living in connubial intercourse may become pregnant without being conscious of it. Dr. Rüttei mentions the case of a female, aged 41, who had been married upwards of sixteen years, and who, while returning from a neighbouring village, was suddenly delivered of her first child, when she had only a few days before been complaining that she was not likely to have any children. The child was born living and mature. (Henke, Zeitschrift der S. A. 1844, 264.) Mr. Long met with a case in which a married woman, aged 24, subject to irregular menstruation, consulted him for an attack of spasms. On his arrival, he found that she had suddenly given birth to a seven months' child. Neither her husband nor herself had the slightest idea that she was pregnant. She had noticed that she had become somewhat stout, and that her breasts were more full than natural. She attributed her condition to improved health, and the cessation of the menstrual discharges was set down to some accidental cause. (Med. Times and Gazette, June 13, 1857, p. 592.)

I am indebted to a distinguished judge for the following fact in reference to unconscious pregnancy:—A married lady, who had not had a child for a period of nineteen years, found herself, as she thought, getting unusually stout. She was moving about with her family to different places. At last her size alarmed her, and she thought she was suffering from dropsy: she consulted a physician, who informed her that she was in an advanced stage of pregnancy. She treated this opinion with great contempt. In travelling with her daughter, they arrived at a miserable inn: on the night of their arrival, this lady was seized with the pains of labour, and was delivered of a child. She had made no preparation for the birth, and, up to the moment when she was seized with labour-pains, she had not, with all her former experience, the slightest idea that she was pregnant. Instances of this kind are important in reference to alleged unconscious delivery in females charged with infanticide. At the same time, many of the cases in which there is a motive for pleading unconscious intercourse or pregnancy, require very close examination. They will frequently be found to be quite unworthy of belief.

Pregnancy in the dead.—There is no special case in law wherein the fact of pregnancy requires to be verified after the death of a female: but an examination may be necessary in order to determine the identity of the body, or to rescue the reputation of
a woman from a charge of her having been unchaste. The discovery of an embryo or fetus in the uterus would of course at once solve the question, when the necessity for an examination occurred, and the practitioner will remember that, even supposing many years to have elapsed since interment, and the body to have been reduced to a skeleton, still if the fetus had reached the period at which ossification takes place, traces of its bones will be found amidst the bones of the woman. In examining the body of a female long after death, for the purpose of determining whether she was or was not pregnant at the time of death, it may be proper to bear in mind that the unimpregnated uterus undergoes decomposition much more slowly than other soft organs. In the case of a female who had been missing for a period of nine months,—whose body was found in the soil of a privy, so decomposed that the bones separated from the soft parts, the uterus was of a reddish colour, hard when felt, and its substance was firm when cut. The fact was of importance. It was alleged that the deceased was pregnant by a young man, and that in order to conceal the fact he had murdered her. From the state of the uterus, Casper was able to affirm that this organ was in its virgin condition, and that the deceased was not pregnant at the time of her death. On this representation the accused was liberated (Geif. Leich. Oeffn. i. 98). In examining bodies many months after interment, and in one case upwards of a year, I have been surprised to find, that while other soft organs were decomposed, the uterus had scarcely undergone any change. Its substance was still firm and hard.

It may happen that the appearances in the uterus are sufficient to create a strong suspicion that the woman had been pregnant, but the ovum, embryo, or fetus may have been expelled. In this case several medico-legal questions may arise in reference to delivery.
DELIVERY.

CHAPTER XLVIII.

Legal relations.—Delivery is a subject which much more frequently requires medico-legal intervention than pregnancy. It will be sufficient to state, that the concealment of birth,—the crimes of abortion and infanticide, with questions relative to supposititious children, are closely dependent on the proof of parturition. This subject will admit of being considered under two heads:—1. As it relates to delivery in the living;—2. As it relates to delivery in the dead. In undertaking the investigation, we ought, if possible, to ascertain, either from the female herself or from those around her, whether there was reason to suspect that she had been pregnant. If we can acquire any knowledge on this point it will materially facilitate our inquiry; but this is not always possible. It has generally happened, that previous pregnancy has been so concealed, that few who saw the woman suspected her condition: then again, as the admission...
of her delivery by a living female may be the strongest proof of her criminality, she will perhaps absolutely deny it; and a medical practitioner has no right to extort this admission from her. From this it will be seen, that a medical witness must often be prepared to prove the fact of delivery, against the subject of the criminal charge.

**Delivery in the living. Concealed delivery.** — The signs of delivery in a living female will vary materially, according to the time at which this event has taken place. In common language, if the contents of the uterus be expelled before the sixth month, the woman is said to miscarry, or to have an abortion; if after the sixth month, she is said to have a premature labour. The law does not admit any such distinction: the expulsion of the ovum, fetus, or child, by criminal violence, at any period of utero-gestation, is regarded as a miscarriage or abortion. It will therefore be proper, in treating this subject, to commence with the earliest period at which the contents of the uterine may be expelled, and to make no artificial distinction between the signs of abortion and delivery. It has been well observed, that the signs of delivery are indistinct in proportion to the immaturity of the ovum. Thus, when it takes place at the second or third month, there are scarcely any proofs which can be derived from the examination of a female. All the ordinary signs of delivery at the full period will be absent,—the development of the embryo not having been sufficient to cause any prominence in the abdomen, or to give rise to those changes in the system which take place previously to the birth of a mature child, e.g. enlargement of the breasts, and dilatation of the mouth of the uterus. Abortion at this period (the second or third month) is generally accompanied by loss of blood, which may manifest itself by its effects on the body. This, however, can only give rise to suspicion. At a later period of gestation there may be a discharge resembling the lochia, and the mouth of the uterus may be found enlarged and soft; but from the small size of the fetus the outlet will present no positive evidence of delivery. The quantity of blood lost may be greater, and may have a more decided effect on the system. Of course, if the ovum or fetus be found, then the presumption of abortion is strongly supported; but those females who designly conceal their condition, will commonly take effectual means to prevent the examiner from obtaining evidence of this kind.

These remarks relative to the state of the female, apply to an examination made recently after the abortion. If any delay take place (and this is a very common occurrence), even the ambiguous signs which have been mentioned speedily disappear; so that after a period, which is short in proportion to the earliness of the expulsion, no traces whatever will be discovered. Dr. Montgomery met with a case in which abortion took place, with considerable haemorrhage, at the close of the second month.
Twenty-four hours afterwards, the mouth and neck of the uterus were almost completely restored to their natural state. The vagina and external parts were hardly, if at all dilated, and very little relaxed; the breasts exhibited very imperfectly, the appearances which accompany pregnancy, the ordinary sympathetic symptoms of which had been almost entirely absent. (Cyc. Pr. Med. 504; Devergie, i. 683.) In such a case as this,—and for such cases a medical jurist must be prepared,—scarcely a presumption could have been entertained of the fact of delivery.

After twenty-four or thirty-six hours, in the greater number of cases of early abortion, we may expect to find from a personal examination of the female, no proofs whatever of this event.

In order to determine the signs of a "miscarriage," as it is termed by our law, at an advanced period of gestation, it will be necessary to describe those which are considered to be characteristic of delivery at the full period. There will be, in these cases only a difference in degree; the signs being more numerous and more clearly marked in proportion to the lateness of the period at which the contents of the uterus are expelled. The signs of delivery may be enumerated in the following order:

Signs of recent delivery in the living.—The female is weak, the countenance pale; the eyes surrounded by livid areolas, and there is an appearance of general indisposition. Any severe illness may, however, give rise to similar symptoms. Their sudden occurrence, from a state of previous good health, especially when pregnancy is known or suspected, will create a strong suspicion.

The breasts are full, especially about the third or fourth day; the nipples are enlarged, and the areolas around them present all the characters of advanced pregnancy.

1. The skin of the abdomen is relaxed, sometimes thrown into folds; the cuticle interrupted by light-coloured broken streaks, passing especially from the groins and pubes towards the umbilicus; and the navel is more or less stretched and altered. The round form of the enlarged and semi-contracted uterus may be felt at the lower part of the abdomen, generally lying towards one or the other side. The apparent size of this organ will depend upon the degree to which it has contracted, and therefore greatly upon the time at which the examination is made.

Dr. Montgomery has pointed out the existence of a dark line, extending from the pubes to the navel, with a dark areola around the latter, in cases of recent delivery; but he has found this line to exist independently of pregnancy and delivery,—in one case in a girl aged ten, and in another instance, in a lady, labouring under ovarian tumour.

2. The organs of generation will be found externally swollen, contused, or even lacerated, with clots of blood about them. The outlet is much dilated; the mouth of the uterus is considerably open, and its margin completely relaxed.
3. The presence of the lochia. This is a discharge, at first of a sero-sanguineous liquid, but which afterwards appears as a brown or green-coloured serum. It commences soon after delivery, and continues from a week to a fortnight, or even longer. The lochial discharge has so peculiar an odour, that some have regarded this alone as furnishing very strong evidence of recent delivery.

The signs which have been here enumerated are found only when no delay has taken place in making the examination, and the woman has been recently delivered. In some strong and vigorous females, the body resumes its natural state within a few days, and the traces of parturition may have either wholly disappeared, or have become so ambiguous as to furnish no satisfactory evidence. In others, again, evidence of delivery will be obtainable for a fortnight or three weeks afterwards. In most cases, however, it is difficult, if not impossible, to say, after the lapse of eight or ten days, that delivery has certainly taken place, the signs having commonly by that time disappeared. In all cases, the earlier the period at which the examination is made, the more satisfactory will be the evidence obtained. Dr. Montgomery once examined a female, five days after delivery at the full time, and he was particularly struck with the degree to which the parts had become restored to their ordinary condition, especially the mouth and neck of the uterus, which hardly differed from their natural unimpregnated form. (Cyc. Pr. Med., loc. cit.)

Signs of delivery at a remote period.—A question may arise, whether it is in the power of a medical practitioner to determine the period at which delivery took place, i.e. how long a time has elapsed. This becomes necessary when, in cases of concealed birth, abortion, or infanticide (some time after suspected parturition), a child is found, and it is required to determine, whether the time which has elapsed since the birth of the child, either dead or living, corresponds with the supposed delivery of a suspected female. An opinion may be given, within eight or ten days after delivery, from the state of the breasts, of the discharges (lochia), and of the mouth of the uterus; but it becomes difficult after the sixth day: and when the tenth or twelfth day has passed, it is still more difficult. After two or three months, it may be regarded as impossible to assign the period of delivery with any degree of precision. (See Devergie, Méd. Lég. i. 446.)

Again, in a case of pretended delivery, contested legitimacy, or disputed chastity (Frazer v. Bagley, see post, Defloration), a medical jurist may be required to say, whether a female has, at any antecedent period of her life, been delivered. This question, it must be remarked, can be raised only in respect to delivery at the full period, since there is no doubt that abortion in the early stages of pregnancy may take place, and leave no traces.
of such an event discoverable in after-life. Indeed, a few days or weeks are sometimes sufficient to obliterate all evidence of the fact. With respect to delivery at the full term, certain signs have been mentioned, which by some are considered indelible. These are,—shining streaks on the skin of the abdomen, a brown mark reaching from the navel to the pubes, and the state of the mouth of the uterus, which is said never to close so effectually as in the virgin. In regard to the appearance of the skin of the abdomen, it may be remarked, that any morbid causes giving rise to a distension of the cavity,—as ovarian enlargement, or dropsy,—will produce the same effect:—so, also, to a certain extent, extreme emaciation from a state of obesity. Then, again, these marks on the skin are not always persistent throughout life. Besides, a woman may be, according to the statements of good observers, not only once, but repeatedly delivered, without having these marks produced.

With regard to the state of the mouth of the uterus, it is liable to vary in different females, and to be affected by disease,—so that a certain judgment cannot always be formed from its condition. In a female who has not borne children, the mouth of the uterus is in the form of a slit, the angles being bent down, and giving to it the appearance of the os tincæ (tench's mouth). Mr. Whitehead has observed that, in a woman who has borne children, the mouth becomes elongated, and loses the slight bend at each of its extremities; the labia are thickened, and more nearly of equal size; the commissures are less clearly defined, and the whole of the neck is enlarged, and not so compact in texture. (On Abortion, p. 195.) It must be remembered, however, that the condition of the mouth of the uterus, even in the virgin, varies at each menstrual period. Should there be occlusion of the vagina, or the hymen be found imperforate, this will at once negative a previous delivery; but the latter condition will not negative a previous pregnancy, since a woman may have been impregnated and have had an abortion in the early stage of pregnancy, without the necessary destruction of the hymen. This sort of negative evidence will, however, sometimes be of great value. There is a total want of good affirmative evidence of delivery at a remote period in the living, so that even a conjectural opinion can be expressed only with caution. It is rare, however, that any decision on this subject is required in medical jurisprudence. It might be demanded, in a case of infanticide, when a woman was accused of having destroyed her alleged offspring some months or years before; or in a case of contested legitimacy, when a female is accused of having substituted a child of which she pretends she has been delivered at some remote period of time.

Feigned delivery. —Delivery has often been feigned by females, for the purpose of extorting charity; compelling marriage, or
disinheriting parties who have claims to an estate, and in other cases without any assignable motive. Of course, an imposi-
tion of this kind could not be sustained before a medical practitioner: and detection is rendered easy, because it is recent and not remote delivery which is assumed. The latter would, if pretended, be generally cleared up by an examination, as well as by circum-
stantial evidence. (See case, Med. Gaz. xix. 231; also another by Capuron, Méd. Lég. des Accouchemens, 110.)

Can a female be delivered unconsciously? — Another important question, relative to the delivery in a living female, is whether a woman can be delivered without being conscious of it. The signs of delivery may be discovered by a practitioner; the off-
spring may also be found. The female may admit the fact of her delivery, but allege that she was totally unconscious of it. The only medico-legal case, in which this plea is occasionally raised, is in infanticide; and as the possibility of the occurrence may be questioned, the practitioner must be provided with a knowledge of those facts which medico-legal writers have accu-
lumulated respecting it. There is no doubt that a female may be delivered unconsciously, if she be labouring under coma, apoplexy, asphyxia, or syncope; or if labouring under the effects of narcotic poisons, the vapours of chloroform and ether, or intoxicating liquors. It is said, also, that delivery has taken place spontaneously while a female was in the act of dying. This, however, has no bearing on the present question. It is in those cases where a female, after her recovery, pleads unconsciousness of delivery, that medical practitioners are chiefly consulted. Besides the cases enumerated, hysteria, when accompanied by loss of sense and motion, has been mentioned as a state in which parturition is liable to occur unconsciously. We need not be surprised at delivery taking place under these circumstances, when we consider that the contractile power of the uterus is altogether independent of volition: but it is difficult to believe, unless the morbid states already mentioned are accompanied by the most profound lethargy and entire loss of sensation, that the con-
tractions of this organ, in its efforts to expel the child, should not suffice at once to rouse the individual into consciousness. We ought particularly to expect this in primiparous females: i.e. in those who have never borne children. At the same time it must be remembered, that parturition with some females, especially when the pelvis is wide and the child small, may take place with such rapidity and ease, as scarcely to be accompanied by pain.

It has been observed, that when a woman has frequently borne children, delivery sometimes takes place without effort, and without any consciousness on her part. On other occasions, the female may lie in a kind of torpor or stupor, and have no recollection of her delivery. Mr. King has described the case of a
woman, aged thirty-six, the mother of nine children. She received his assistance in her tenth labour: when summoned, she was lying calmly and placidly in bed, and was perfectly insensible. He found that the child had been expelled with the placenta. The woman did not recover her sensibility for ten or twelve hours, and then stated that she had no recollection of the birth of the child, or of any circumstances connected with that event. She suffered no pain or uneasiness. Another case is mentioned by this gentleman, in which sensation appeared to be entirely paralysed during labour. (Med. Times, May 15, 1847, 234.) It is beyond doubt, that profound lethargy occasionally makes its appearance about the time of delivery. Dr. Schulze met with a case in which a female remained in a state of sleep for three days, and was delivered while in this unconscious condition: on awaking, she had no recollection of having suffered any pain during delivery. (Ann. d’Hug. 1845, i. 216; Med. Gaz. xxxvi. 40.) Dr. Montgomery relates the case of a lady, the mother of several children, who, on one occasion was unconsciously delivered during sleep. (Cyc. Pr. Med. See also case in B. and F. Med. Rev., No. ix. p. 256.)

The results obtained by the use of the vapours of chloroform and ether, show that the expulsive efforts of the uterus are often as energetic in the unconscious, as in the conscious state. It may appear extraordinary, however, that a primiparous female, unless rendered unconscious by narcotic substances, should be delivered without suffering pain: nevertheless, a case of this kind is recorded by Dr. Wharrie. The woman’s age was twenty-one; she had been in labour about six hours; she complained of no pain, and the child was borne without effort or consciousness. The child was healthy but small, weighing rather more than four pounds. (Cormack’s Journal, Jan. 1846, 12.) Notwithstanding this case, it is in the highest degree improbable that any primiparous female should be delivered during ordinary sleep, without being roused and brought to a sense of her condition.

There is another condition in which a woman may state that her delivery took place unconsciously; and this, from its being one of the most common species of defence set up by a female charged with child-murder, must here claim our attention. Thus she will allege that, while suffering from pain, she felt a strong desire to relieve her bowels; that she went to the water-closet for that purpose, and was there delivered without knowing anything of the occurrence, until it was too late to save the child. This kind of desire is a very common symptom of the parturient state; and, as it has been elsewhere remarked, it is often difficult in private practice to restrain a woman from yielding to the feeling, when it certainly would be attended with hazard to the child. (For a case of this kind see Med,
Times and Gazette, April 4, 1857, p. 347.) We must therefore admit that an accident of this kind is quite within the range of probability; although here, as in every other instance in which unconscious delivery is pleaded, a medical witness ought to inform himself, or to be informed, of all the particulars which are stated to have attended delivery, before he gives an answer specially applicable to the case. As a general rule, it cannot be denied that delivery may take place, under these circumstances, and a woman not be conscious of it: but, before we make the admission in regard to any particular instance, we ought to have a full statement of the facts from the female herself. It is thus that we shall avoid the risk of seeing a premature medical opinion set aside by the subsequent production of circumstantial evidence. Besides, it has been very properly observed, that after an accident of this kind, a woman cannot be ignorant of her having been delivered. Females who have raised this plea in cases of child-murder, have often been known to maintain that they were unconscious of their pregnancy; and thus have attempted to excuse themselves for not having prepared the articles necessary for childbirth. It is possible that a female may not be aware of her pregnancy in the earlier stage; but it is scarcely credible that she should remain ignorant of it in the later period of gestation, or up to the time of her delivery. It is at least to be presumed that she must have some reason to suspect her condition; and if only a suspicion existed in the mind of a woman who did not contemplate the destruction of her future offspring, there would assuredly be many circumstances forthcoming which would establish her innocence. If this remark applies to married women, it applies with still greater force to those who are unmarried, since the fact of illicit connection and the fear of its consequences must render them peculiarly alive to all those changes which, by common repute, take place in the female system during pregnancy.

Signs of delivery in the dead. — It will now be proper to examine the signs of delivery which are derivable from an examination of the body after death. Occasionally, we may obtain some account of the female during life, by which our labour will be much facilitated; but, on the other hand, every fact may be studiously concealed from us, and then we may be required to prove not only the delivery, but the previous pregnancy. These investigations relative to pregnancy and delivery in the dead body, are almost exclusively confined to cases of criminal abortion, where the contents of the uterus have been expelled at the sacrifice of the life of the woman. Death commonly ensues in these cases within two or three days after delivery; and then satisfactory proofs are obtainable on an examination of the body: but, if the female has survived three or four weeks, it will be as difficult to determine delivery in the dead as in the
CONDITION OF THE UTERUS.

living subject. This remark applies to delivery at the full period: for if the uterus have expelled its contents in the first months of pregnancy, the traces of this expulsion will have generally disappeared in the course of a few days.

According to Burns, the following may be taken as the chief appearances when the body is examined soon after delivery at the full period. The uterus is like a large flattened pouch from nine to twelve inches long, its mouth being wide open. The cavity contains coagula of blood or a sanguineous fluid; and its surface is covered with the remains of a decidua. In the part to which the placenta has been attached, the substance of the organ appears exposed, presenting several large semilunar or valvular openings. This portion of the uterus is of a very dark colour, so as to have given rise to a suspicion that the organ was gangrenous. The vessels are extremely large and numerous. The Fallopian tubes, round ligaments, and ovaria, are so vascular (full of blood) that they have a purple colour. The spot whence the ovum has escaped is more congested than the rest of the ovarian surface. Obstetric writers differ greatly in their statements respecting the size of the uterus at different periods after parturition; and these differences may be explained, partly by the fact that the uterus contracts more rapidly in some females than in others, and partly, perhaps, by the circumstance of the birth having been, in some instances, premature. Dr. Montgomery states that, after delivery at the full period, and under perfect contraction of the uterus, if the body be examined within a day or two, it will be found seven inches long and four broad. Its paries, on making a section, will be from an inch to an inch and a half in thickness, and will present the orifices of a great number of large vessels. At the end of a week the organ is between five and six inches, and at the end of a fortnight about five inches in length:—the density of the paries has during this period increased, but their thickness or substance has considerably diminished. The inner surface is still bloody, and covered partially with a pulpy substance resembling the decidua. The orbicular direction of the fibres around the internal orifices of the tubes is at this time very distinct. In about a month the uterus will have become fully contracted; but the mouth rarely, if ever, closes so completely as in the virgin state. In a case examined by Dr. Barnes, in which a primiparous female, aged 26, died from puerperal fever on the sixth day after delivery, the following appearances were met with in the uterus. The internal surface was blackened and congested, especially in those parts to which the placenta had been attached. There was the appearance of suppurative action in this part. The substance of the uterus was healthy: there was no pus in the sinuses. The os uteri showed considerable ecchymosis. The vagina was healthy; the iliac veins contained nothing but loosely coagulated blood. There was in the left

The vagina was healthy; the iliac veins contained nothing but loosely coagulated blood. There was in the left.
ovary a small well-marked corpus luteum, having a central cavity.
(Med. Gaz. xli. 294.)

From this statement of the appearances, it will be seen that there must be considerable difficulty in determining the period prior to death at which delivery took place. The difficulty is increased when the female has been prematurely delivered, and death has not taken place until some time after delivery. A medical opinion may be then in some degree strengthened by searching for those signs which have been described as characteristic of delivery in the living. These, if present, will almost furnish strong corroborative evidence, not only of the fact of delivery, but of the period at which it had probably occurred.

Evidence afforded by the presence of corpora lutea.—The condition of the ovaries has been considered to furnish very strong evidence in the dead body, not so much of delivery as of previous pregnancy. These organs, as it has been already stated, when examined soon after delivery, are found of a deep purple colour, owing to their extreme vascularity. If the female has really been pregnant, we may expect to find, on one or the other of these bodies, the appearance which is denominated a corpus luteum. The accounts given by obstetric writers of the characters of corpora lutea, and the evidence which they are capable of furnishing in legal medicine, are very conflicting. Dr. Montgomery states that, in the true corpus luteum (i.e. of pregnancy), the ovary presents a protuberance with a distinct cicatrix on some part whence the ovum has escaped. The protuberant part will be found on section to have an oval form and to be of a dull yellow colour. It is very vascular, and in texture resembles the section of a kidney. In the centre of this section there will be either a cavity or a radiated white cicatrix, according to the period at which the examination is made. The cavity remains for about three or four months after conception, and is surrounded by a strong white cyst.—as gestation advances, the opposite sides approximate and a radiated white cicatrix results. The size and vascularity of the corpus luteum are considerably diminished by the time gestation is completed; and in about five or six months afterwards, i.e. fourteen months after its first formation, it disappears altogether from the ovary, so that the corpus luteum of one conception is never to be found with that of another, unless a premature expulsion of the contents of the uterus has taken place. (Cyc. Pr. Med. Pregnancy, 496; see also Edinb. Monthly Journal, Jan. 1845, p. 58.) The presence of a corpus luteum, as it is here described, does not prove that a woman has borne a child. In the opinion of some obstetric authorities, it establishes that conception has taken place: but the embryo may have been converted into a mole or a blighted fetus, and expelled at an early period. It was formerly supposed that one true corpus luteum only was met with in pregnancy with one child; but among other facts which show
TRUE AND FALSE CORPORA LUTEA.

that such an inference is erroneous, is a singular case reported by Dr. Renaud to the Manchester Pathological Society. He examined the body of a female who died in the seventh month of her pregnancy, and from whose uterus he extracted a fetus. There were no traces of a blighted ovum. The ovary, however, presented two distinct and well-marked corpora lutea. (Med. Gaz. xxxix. 599.) Had the ovary alone been examined, it might have been supposed that this female had had twins.

The characters of what has been hitherto denominated the false corpus luteum have been thus described:—1. There is no prominence or enlargement of the ovary generally, at the part where it is situated. 2. The external cicatrix is wanting. 3. There are often several in both ovaries. 4. The texture is not glandular, nor can it be injected. 5. When laid open by section, it has neither a central cavity, nor the peculiar radiated cicatrix which results from its closure. Dr. Paterson has published some remarks on this subject, with medico-legal cases and plates. (Ed. Med. Sur. Jour. liii. p. 49.) According to this gentleman, the false are to be distinguished from the true corpora lutea by the following signs. They have in general an irregular form, and want either a central cavity lined with a distinct membrane, or a puckered cicatrix. They have no concentric radii, and are frequently numerous in both ovaries. He relates the following case, in order to show that the presence or absence of a true corpus luteum may be sometimes important in a question of disputed identity in the dead. Four medical students were charged with having disinterred the body of a lady; but the body was so disfigured that the deceased could not be identified by her relatives. In one of the ovaries a true corpus luteum was reported to have been found; a discovery which, if true, proved that it could not be the body of that lady, since she was a virgin, and advanced in life. On the trial the medical evidence was very conflicting; one half of the witnesses maintained that the body which was found in the ovary was a true corpus luteum, while the others contended that it was not! Dr. Ramsbotham agrees with Drs. Montgomery and Paterson in considering that the true corpus luteum, i.e. that derived from conception, is known either by its having a central cavity, sometimes unoccupied, at others filled with the blood which was effused at the time that the coats gave way, or if it should be of more ancient date, by its presenting stelliform radiated white lines (a puckered cicatrix), resulting from the closing of this cavity. (Obstetric Medicine, p. 49.) The reader will find the appearances described well delineated in Dr. Ramsbotham's work.

In opposition to the views of Drs. Montgomery, Paterson, and Ramsbotham, Dr. Knox, an experienced anatomist, asserts that there is no distinctive character whereby what has been called the true, can be known from the false corpus luteum, the only
difference being that the latter is smaller. What have been called corpora lutea may be formed in virgin animals, independently of intercourse; and the time of their disappearance in the ovary varies from three months to an almost indefinite period. (Med. Gaz., Dec. 22, 1843.) That there is considerable difficulty in distinguishing true from false corpora lutea, is proved by reference to a case reported in the Medical Gazette (Vol. xxxiv. p. 633) in which two experienced observers differed. Dr. Lee thought that the preparation which was the subject of examination was not a corpus luteum, while Mr. Wharton Jones thought that it was,—founding his decision on a microscopical examination. This difference of opinion shows that a distinction is by no means so simple a matter as some writers assert. Mr. W. Jones agrees with Dr. Knox in considering that a corpus luteum may occur in the ovaries, independently of intercourse; and that the existence of one in this organ would therefore afford no proof whatever of intercourse having taken place. The discovery of the ovum in the uterus, in process of development, could alone, in the present state of our knowledge, warrant an affirmative opinion on this point in a Court of law; and this I believe to be the safest view of this much-contested question. On the other hand, the absence of a corpus luteum from the ovary would not in all cases warrant the opinion that conception had not taken place.

These views regarding the evidence derivable from the presence of corpora lutea have received considerable support from the researches of Professor Bischoff. (Med. Gaz. xxxv. 443, et seq.) The experimental investigations of this gentleman appear to show that the extrusion of an ovum, or the production of a corpus luteum, is by no means necessarily connected with conception—that the ova undergo a periodical maturation, about the time of menstruation, and escape whether there be conception or not;—therefore that fecundation is only likely to occur when intercourse is had about this period. This is also the opinion of Raciborski: indeed, some physiologists now regard menstruation as the alternative of conception (see Dub. Quart. Jour., May 1846, p. 436), and consider that there is no period so favourable to conception, as that which immediately follows the cessation of the menses. In this respect the Koran appears to conflict with the laws of physiology, since it is laid down by Mahomet that females are impure for eight days before, and eight days after menstruation. (Rostan, Cours d’Hyg. ii. 438.) The same custom, according to Meigs, exists among the Jews as to the period at which a woman is clean after the cessation, (Obstetrics, 128.) It is not a little singular that this comprises the period at which, according to modern theories, conception most readily takes place. Women may conceive during the flow of the menses: it is also well ascertained that a woman who has never menstruated may con-
ceive, and that conception may take place one or two days before the period of menstruation. Raciborski has met with several instances in illustration of these views. (Advances in Physiology, Baly and Kirkes, p. 59.) In the theory above given, we have an explanation why corpora lutea, or bodies closely resembling them, are so often found in virgin animals, and it would also account for those differences of opinion among experienced men, which almost invariably occur when it becomes a debated question whether a corpus luteum be true or false. The theory would further explain cases like the following, reported by Mr. Elkington:—A woman aged forty-two, who had not borne a child for seven years, died from diseased lungs. On the right ovary were two corpora lutea; and the Fallopian tube on that side was larger and more congested than on the other. The deceased expected to menstruate on the day she died, or at least one day later. (Prov. Med. Jour., Feb. 1845, 104.) Dr. Ritchie, of Glasgow, has arrived at results which tend to confirm the views of Professor Bischoff and Mr. W. Jones. He calls the bodies corpora menstruata vel periodica. They may, in his opinion, be formed independently of pregnancy, and may possibly assume all the characters of what are called corpora lutea, by some reflex excitement in the uterine organs. According to this gentleman there are no fewer than eight varieties, which are liable to have their characters intermixed. (Med. Gaz. xxxvi 985, 1058.) A recent case, in which a well-marked corpus luteum was found coinciding with menstruation in a female who had been executed, is reported by Dr. Michel. (Med. Gaz. xlv. 307.)

A full account of the general and microscopical characters of true and false corpora lutea, by Dr. Renard, will be found in the Edinburgh Monthly Journal, August 1845, p. 589. (See also Recent Advances in Physiology, by Drs. Baly and Kirkes, 1848, p. 46.) These gentlemen conclude from their researches, that cases can seldom occur in which the mere presence of a corpus luteum can be taken as a proof of previous impregnation; and they consider the following rules to be deductible from the facts which they have collected. 1. A corpus luteum in its early stage (that is, a large vesicle filled with coagulated blood, having a ruptured orifice, and a thin layer of yellow matter within its walls) affords no proof of impregnation having taken place.—2. From the presence of a corpus luteum, the opening of which is closed, and the cavity reduced or obliterated, (only a stellate cicatrix remaining,)—no conclusion, as to pregnancy having existed can be drawn, if the corpus luteum be of small size, and does not contain so much yellow substance as would form a mass the size of a small pea.—3. A similar corpus luteum of larger size than a common pea would furnish strong presumptive evidence, not only of impregnation having taken place, but of pregnancy having existed during several weeks at least; and the
evidence would approximate more and more to complete proportion as the size of the corpus luteum was greater. (Op. cit. p. 57.)

From this statement, it will be perceived that the different size, as in pregnancy corpora lutea are found of very variable size; while in menstruation they may, under great excitement, and a large size, it is obvious that no safe inference can be drawn from their presence, irrespective of other signs of impregnation. The terms true and false, therefore, are inappropriate; and the most serious mistakes may arise by a reception of evidence on this point. The law requires absolute certainty, not merely probability or presumption; and, in the present stage of physiology, the proof falls short of that which is necessary to guide the verdict of the jury. At a trial for attempted abortion, Reg. v. Goodall (New York County Court, 1846), on examining the body of the female in whom the attempt was alleged to have been made, it was found that she was not pregnant; but on inspecting the ovary, a corpus luteum was there discovered. This was described as false, apparently because there was no proof of impregnation. Had an embryo been found in the uterus, or had there been proof of its expulsion, it would probably have been described as true. Dr. Meigs, an experienced writer, says that corpora lutea may vary in size, but in all cases they are real. Physiologically speaking, they do not admit of a division into true and false. (Females, and their Diseases, 1848, p. 45. See Ed. Mon. Jour., Oct. 1851, 309.)

From these considerations, therefore, it appears to me that the only conclusion to which we can come is that medical evidence respecting the nature of a corpus luteum in an unknown case, received in a Court of law at all, should be received with the greatest caution, and only from a witness of great experience. The old doctrine on this subject, that the presence of such a body on the ovary affords certain and undeniable evidence of impregnation, may be regarded as completely subverted.

Characters of the ovum or embryo to the sixth month. — Hitherto the examination has been confined to the female; but it is not necessary to describe the characters of the ovum or embryo in the early stages of pregnancy, since, when this can be procured, good medical evidence may be derived from an examination of it. If the ovum be expelled within a month after conception, it is scarcely possible to detect it, owing to its small size, and its being enveloped in coagula of blood. Burns examined the uterus, within the first month, where no expulsion had taken place, but even under these favourable circumstances he failed in discovering the ovum. At first the ovum contains no visible embryo; but it appears merely to consist of vesicular membranes and coverings. According to this writer, when first distinctly seen through its membranes, it is of an oblong form and about a line
(the twelfth of an inch) in length. At the sixth week, it is slightly curved, resembling, as it floats, a split pea. In the seventh week it is equal in size to a small bee; and by the end of the second month it is bent, and as long as a kidney-bean. After this, development goes on rapidly: the features are in part well marked, and the extremities are gradually formed. At the third month, the fetus weighs from one to two ounces:—when stretched out it measures about three inches, and the genital organs, although the sex is not distinguishable, are large in proportion to the rest of the body. The membranes are larger than a goose’s egg. At the fourth month the fetus is from five to six inches long, and weighs from two to three ounces; at the fifth month it measures from six to seven inches, and weighs from five to seven ounces; and at the sixth month, its length is from eight to ten inches, and its weight about a pound. (For the characters of the child beyond this period, see ante, p. 425.) The great difficulty will consist in determining the nature of the supposed ovum or embryo between the second and third month. In making the examination, it should be placed in water, and all coagula gently washed away or removed by some blunt instrument. Alcohol may be used as a substitute for water, after the blood has been removed. If the embryo cannot be found, the decidua and chorion may be recognised:—the former, by its forming the outer investment with its smooth internal and rough external or uterine surface; the latter, by the villous appearance of that portion of it which would have become the placenta. Between the third and fourth month, the fetus may be commonly identified without much difficulty.

Moles.—The substance expelled from the womb may have been what is termed a mole—a morbid production of a fleshy or of a bloody structure, appearing like a blighted ovum or placenta. It has been said that a mole is never formed in the virgin uterus, but that its presence always indicates previous sexual intercourse: this point, however, is far from settled. The term mole is also applied by some to coagula of blood, polypi, or hydatidae. In one case reported, a mole and an ovum were expelled together,—a fact which shows that they may coexist. The symptoms accompanying a mole strongly resemble those of pregnancy; and the appearances produced by its expulsion are not to be distinguished from those attending the abortion of a fetus at an earlier period of gestation. The only means of distinction would be derived from an examination of the expelled matters. The local injury produced by the expulsion of these bodies on the organs of generation, is by no means so great as that caused by delivery at the full period.

Hydatids.—The signs of pregnancy and delivery may be present in a female, and yet these may be owing to the existence of hydatids in the womb. It was formerly a question, whether con-
ception or previous impregnation was or was not necessary to their formation. Dr. Koch, of Heiligenbeil, has reported a case in which they were probably produced independently of sexual intercourse. A healthy strong woman, 32 years of age, had been married nine years, and had borne four children without difficulty. At this time she was living apart from her husband, so that according to the declaration of both there could have been no intercourse. The menstrual function ceased after the weaning of the last child, and the patient observed that her abdomen became enlarged, as if she were again pregnant. After three months’ suffering, during which she was continually upbraided by her husband in consequence of her condition, pains came on, and a hydatid mole (a cyst of hydatids) about the size of two fists was extruded. The hydatids were collected in a grape-like cluster, and the cysts varied in size from a hemp-seed to that of a walnut. (Wildberg, Jahrbuch der gesammten S. A. 1837, I Heft, 145.) Dr. Ramsbotham considers that the difference of opinion regarding the production of these growths in virgins, may be explained by the fact that two diseases, totally dissimilar in their origin, character, and progress, have been confounded. (Med. Times and Gaz., Feb. 26, 1853, p. 210.)

In a case communicated by Mr. Hunter to the Lancet, hydatids coexisted with pregnancy, and the mass came away on the birth of the child. (April, 1846, p. 430.) When the mass is expelled, it is found to consist of a group of vesicles or cysts of various sizes; but sometimes, when this disease follows intercourse, the cysts are found mixed either with the remains of a blighted ovum or a coagulum of blood. Unless the expelled matters be produced, it would be very difficult to say from an examination during life or after death, whether the uterus had contained an embryo or hydatids. These morbid growths may even be inclosed in an investing membrane similar to the decidua, and there may be the remains of a corpus luteum in the ovary; but it is not likely, when carefully examined in water, that they can be mistaken for an ovum or embryo. (An interesting case of the conversion of an ovum into hydatids will be found in the Med. Gaz. vol. xlvii. p. 454.)

In examining the bodies of those who have died while labouring under uterine hydatids, it has been found that occasionally the whole of a blighted ovum is converted into them; but sometimes only a part is thus converted. The cysts vary in number; there may be only one large cyst, and it is said this condition is more frequently met with when hydatids are combined with pregnancy or with a mole, than when alone. The hydatid cysts appear to be connected with the inner surface of the uterus, by the unchanged portion of the ovum or placenta; and thus, upon their removal, we might expect to find the uterine surface more or less similar to that of the gravid state, according to the degree
of development which may have taken place in the ovum. Burns observes, that the relative magnitude of the vessels in the two states has not been ascertained; few opportunities being afforded for examining the state of the organ in this disease. According to Madame Boivin, the hydatids are sometimes surrounded by an investing membrane similar to the decidua. In a case which occurred to Mr. Brown, the symptoms caused by uterine hydatids were mistaken by the female (a married woman who had had children) for those of true pregnancy. The catamenia had ceased for about four months, the breasts were enlarged, there was a darting pain through them, with soreness of the nipples, and morning sickness. In about a month, flooding took place and the hydatids came away. (Obstetric Record, i. 21.) These facts may have an important bearing on medico-legal practice, and in this respect, the following case, reported by Dr. Chowne to the Westminster Medical Society, Nov. 1843, will be found of interest: — A woman was seized with pains resembling those of labour, and a mass of uterine hydatids was expelled, which were supposed to have been in the uterus about five months. When the woman was examined, thirty-six hours afterwards, there were all the signs of recent delivery about her. The parts of generation presented the usual appearances met with on the expulsion of a fetus; the breasts were enlarged, the areolae elevated, of a brown colour, the follicles prominent, and the organs evidently contained milk. The occurrence of this case led Dr. Chowne to think, that had the body of an infant been found with marks of violence concealed in the house where this woman lived, it would probably have been pronounced to be her child. A medical man might have strengthened the suspicion of criminality by declaring that there were all the signs of delivery about her. It may be observed, however, that in such a case, the woman would probably have stated that no child, but some tumour, had come away from her; and a medical man would not be justified in swearing that appearances of delivery absolutely indicated, under all circumstances, that the woman must have been delivered of a child. On the contrary, it is a well-known medical fact, that similar appearances may arise from the expulsion of a mole or hydatids. Circumstantial evidence would be against her, only on the assumption that some person had wilfully concealed or made away with the substantial proof of her innocence, i. e. the group of hydatids which had been expelled. Mr. Pearson has communicated to the Medical Times (Dec. 30. 1848), a case in which, after the expulsion of a mass of hydatids, there were all the appearances which are usually observed after delivery.

Some of the questions which have been here considered were raised on the trial of Angus for the murder of Miss Burns, at the Lancaster Assizes, 1808. It was alleged that the deceased was pregnant,—that the prisoner had administered corrosive salo-
mate to her for the purpose of inducing abortion, and that this had caused her death. A question was raised at the trial relative to the appearances presented by the uterus as indicative of recent delivery. On examining this organ, it was found to be considerably enlarged, and on its inner surface was a mark, about four inches in diameter, plainly discernible, to which the placenta had been apparently attached. The mouth of the uterus was much dilated. Indeed, the appearances were described to be such as might have been expected to be found two hours after the birth of a full-grown child. The evidence respecting previous pregnancy was conflicting; and the prisoner was acquitted, because the death of the deceased could not be distinctly traced to any criminal act on his part. The ovaries were not examined until after the trial, when a body which was considered to be a true corpus luteum was found on one of them; and some eminent authorities agreed that it indicated an advanced state of pregnancy. (See Paris and Fonblanque, Med. Jur. ii. 179.) One medical witness appeared for the prisoner; and he contended that the state of the uterus did not justify the medical inference that there had been recent delivery. He assumed that the appearances might have been due to the expulsion of a group of hydatids. On the whole, the medical defence, so to term it, appears to have been more ingenious than sound; and to have rested upon assumptions which, if generally admitted, would effectually do away with all medical evidence in cases of criminal abortion. The contents of the uterus were not produced,—a fact which left the case in mystery.

CONCEALMENT OF BIRTH.

CHAPTER XLIX.

Concealment of birth.—Medical evidence respecting delivery is required in two cases: 1, when the birth of a child is wilfully concealed; and 2, when the contents of the uterus have been
prematurely expelled by criminal means. The concealment of pregnancy is no offence in the English law; but the concealment of delivery or of the birth of a child is a misdemeanour by the 9th Geo. IV. c. xxxi. sec. 14, the words of which are to the following effect:—

"Be it enacted, that if any woman shall be delivered of a child, and shall, by secret burying, or otherwise disposing of the dead body of the said child, endeavour to conceal the birth thereof, every such offender shall be guilty of a misdemeanour; and, being convicted thereof, shall be liable to be imprisoned with or without hard labour in the common gaol or house of correction for any term not exceeding two years; and it shall not be necessary to prove whether the child died before, at, or after its birth."

This is an offence of which those females who are charged with infanticide are most commonly convicted in England; while the Scotch law punishes females for the concealment of pregnancy, if the child be dead or missing. (Alison's Criminal Law, 153.) The medical evidence on trials for this offence is exclusively derived from an examination of the mother; and thus, much will depend upon the time at which this is made. With respect to the child, its body need not even be produced, provided there be satisfactory evidence of its death, and its body has been secretly buried or otherwise disposed of. In the case of the Queen v. Varney (Oxford Lent Assizes, 1837), it was proved that the woman had been pregnant, and subsequently delivered of a child. Its body had been burnt, and only a few remains of the bones of a human foetus were found in the ashes of a grate. The prisoner was convicted of the offence. In a case like this, in which an attempt has been made to destroy the body of a child by burning, it will, of course, be necessary to have good evidence that the bones are those of a human foetus or child. They may retain their shape whether burnt in a close fire or in the open air: in the latter case alone they will be white. A small fragment only of either end of any well-marked bone will suffice for identification. If burnt to a complete ash or powder it will then be difficult to identify them. Orfila was consulted in a case of this kind, where a woman had burnt her child in an oven, and its ashes had become mixed with those of wood. He suggested, that on calcining the residue with potash, the ashes of a human foetus might be known by their yielding cyanide of potassium, owing to the nitrogen which would remain in and about them. The ashes of wood do not yield the cyanide under similar circumstances. (Ann. d'Hyg. 1845, ii. 129.) The conclusions drawn under such circumstances might, it appears to me, lead to a serious error:—the presence of a flannel dress, of an old hat, shoe, or any nitrogenous substance, would, on incineration, give rise to precisely similar results. When the form of a bone cannot be recognised, all that medical evidence can, as it appears to me, accomplish, is
this:—The detection of a large quantity of phosphate of lime in the ash would indicate that bones were present, and thus distinguish the ash of bone from the ashes of other substances. Still the bones might have belonged to an animal, and not to a human foetus. There are no means of distinguishing the ash of human, from that of animal bone, or the ash of foetal from the ash of adult bones.

In Reg. v. Berryman (Guildford Summer Assizes, 1854), the prisoner was tried and acquitted on the charge of concealment of birth. She admitted that she had burnt the body of the child, and some calcined bones were produced, but these, it is reported, did not strictly correspond. The child was alleged to have been a seven months' child, but part of the skull produced corresponded to that of a nine months' child, or of one even older.

According to the statute, the child must be dead—the concealment of the birth of a living child not being any offence, unless it should happen to die before its birth was made known. In the case of the Queen v. Woodman (Kingston Lent Ass. 1845), the woman was acquitted because the child was living when concealed. Mr. Chitty says, that, in order to constitute the offence, the child must have advanced to the end of the seventh month (Med. Jur. 412); but it is to be presumed that the concealment of the birth of a dead child at the sixth or under the seventh month, would be as much an infringement of the statute as if it were more advanced. The concealment of the aborted but undeveloped ovum—a monster, i.e. of a child without human shape, a mole or other morbid growth, would not probably be considered a contravention of the statute. I am not aware that there has been any judicial decision on this point. Mr. Lane communicated to the Medical Times (Aug. 1845) a case in which a charge of concealed birth was dismissed by the magistrates of Surrey, because the concealment referred to a child born at the eighth month in its membranes. The woman stated that she did not consider it to be a child! If this decision be correct, the main object of the statute (i.e. to prevent secret delivery, so often leading to murder) may be effectually evaded. The case, being entirely new, should have been sent for trial, and the decision left to the proper interpreters of the law. A magisterial decision can furnish no precedent on a question of this kind. The woman must have been delivered of a child, foetus, or embryo, or of course there would have been no pretence for the charge. A singular case of alleged concealment of birth occurred at the Suffolk Lent Assizes, 1853. A married woman was charged with having concealed the birth of her infant child. It appeared that her husband and the neighbours supposed she was pregnant. After the child was reported to have been born, it was alleged that it had died, and preparations were accordingly made for the burial. The coffin was examined, and was found to contain not the body of a child but the figure
of a doll. The learned judge directed the Grand Jury that before they could find a bill, charging the prisoner with the guilt of concealment, they must be satisfied (but of this there was no evidence on the depositions) that the woman had really been delivered of a child. The prisoner had been a married woman for a number of years, and her conduct could only be accounted for on the supposition that she had endeavoured to impose upon her husband and her neighbours. The case fell to the ground.

It will be perceived that it is not material here, as it is in a case of alleged infanticide, to prove when the child died,—whether before, during, or after its birth; and thus those subtleties and technicalities which have been elsewhere pointed out in cases of infanticide are avoided. In regard to proof of concealment, and what constitutes it, these are essentially legal points:—but a medical practitioner may sometimes benefit an accused party, if he can prove that the female had made application to him on the subject of her pregnancy and delivery. The law is especially lenient under such circumstances. Questions connected with concealment of birth do not fall under the jurisdiction of a coroner:—the medical evidence is therefore required by a magistrate. Medical witnesses were formerly exposed to much trouble and inconvenience in giving their evidence on these occasions (See Med. Gaz. xix. p. 287); but the defect has been remedied by a recent statute. (1 Vic. c. xlviv.)

In a case under the Scotch statute in reference to the concealment of pregnancy, for a report of which I am indebted to an eminent legal authority, a curious question arose, viz. "Whether the charge was excluded if the woman, an unmarried female, proved that she had intimatd that she was with child to the father, but denied the pregnancy to every one else. That the object of the statute was defeated in such a case, and yet that the main fact on which the statutory offence is founded was proved, could not be doubted. Concealment, and not calling and making use of assistance in the birth, constitute the offence. The Court of Judiciary was nearly equally divided. The majority went on the bare terms of the statute: the minority held that concealment was here a general term to denote the denial to all near and around the woman, and from whom assistance might be obtained, and was coupled with not calling for assistance in the birth. As a letter written to Australia, if the father had gone there, could not be taken to exclude the statutory offence, and as the woman concealed her pregnancy and had obtained no assistance in the birth, an expression which shows what the character of the concealment referred to is, the communication of the fact of pregnancy to the father of an illegitimate child (often more anxious to get rid of the child than the mother) really could not lead to its preservation, and left the concealment which the statute referred to equally complete. But the point was not
actually decided, as it was thought that the terms of the special verdict did not raise the question, but by an accidental form of expression, excluded it."

---

CRIMINAL ABORTION.

---

CHAPTER L.

General remarks.—By abortion is commonly understood, in medicine, the expulsion of the contents of the uterus before the sixth month of gestation. If the expulsion take place between the sixth and ninth month, the woman is said to have a premature labour. The law makes no distinction of this kind, but the term abortion is applied to the expulsion of the fetus at any period of pregnancy before the term of gestation is completed; and in this sense it is synonymous with the popular term miscarriage. Criminal abortion is rarely attempted before the third month;—it is perhaps most common between the fourth and fifth month; because then a female begins for the first time to acquire a certainty of her pregnancy. The causes of abortion may be either natural or violent. The latter only fall under the cognizance of the law;—but a medical witness should be well acquainted with the causes which are called natural, in contradistinction to others which depend on the application of violence. These natural causes are so frequent, that, according to Mr. Whitehead's observation,—of 2000 pregnancies, one in seven terminated in
abortion. These causes are commonly ascribable to peculiarities in the female system,—to the presence of uterine or other diseases, or to some moral shock sustained by the woman during pregnancy. Any diseases which strongly affect the uterus or general system of the female may give rise to abortion. An attack of small-pox has been known to produce it; and it has been suggested by Mr. Acton, that the presence of constitutional syphilis in the father is not only a cause of infection in the offspring, but of repeated abortion in the female. (Med. Gaz. xxxvi. p. 164; Ramsbotham’s Obstetric Medicine, p. 655.) These facts deserve attention, when it is proved that a woman has really aborted, and an attempt is unjustly made to fix an alleged act of criminality on another. For further information on the numerous natural and accidental causes which may give rise to abortion, the reader may consult the work of Mr. Whitehead (On Abortion and Sterility, p. 252. Also, for the effects of undue lactation and disease of the placenta, see Med. Times and Gaz., Dec. 4, 1852, p. 580, and March 19, 1853, p. 302.) In considering the operation of these causes, it is proper to bear in mind that during pregnancy the uterus is considered to be subject to a natural periodical excitement, corresponding to what would have been the menstrual periods dating from the last cessation. Hence comparatively trivial causes operating at these periods may lead to an expulsion of the fetus.

The violent causes of abortion may be of an accidental or criminal nature. In general, the distinction will not be difficult:—the kind of violence, and the adequacy of the alleged cause to produce abortion, will be apparent from the evidence. The causes of abortion in criminal cases may be referred either, 1, to the use of mechanical means, or 2, of irritating medicinal substances acting upon the uterus or bowels. These causes operate with greater certainty just in proportion as the pregnancy is advanced.

Mechanical means.—Among the mechanical causes may be mentioned—undue exercise, the violent agitation of the body, as by riding or driving over a rough pavement, in which case no marks of violence would be apparent. Any physical shock, sustained by the body, may operate indirectly on the uterus. Blows or violent pressure on the abdomen are sometimes resorted to; but in these cases the marks of violence will be commonly perceptible. Instruments have been devised for the purpose of piercing the membranes, destroying the child, and thereby leading to its expulsion. Devergie speaks of such instruments being well known in England, and of English midwives deriving a living from the practice of this crime (i. 285.) Although this must be regarded as an exaggerated statement, it cannot be denied that within the last few years many cases have transpired which show that the crime is frequently perpetrated by persons who basely derive a
a female is pregnant or no fact that a speculum is not required of pregnancy at all. This case of members of the medical profession.

Medicinal substances. — These are resorted to for inducing criminal abortion, but they rarely answer the intention. If a result is obtained, it is generally at the mother. Mineral poisons have been introduced; as arsenic, corrosive sublimate, muriate of iron (Reg. v. Wright, 1855), and other irritants. Croton oil, aloes (Henke, Zeitschrift, 1844, ii. 20 p. 145), elaterium, and other drastic remedies used for a similar purpose. Purgative straining, — powerful emetics or diuretics used in these advanced stages of pregnancy, medicines fail in their effect at the stage just mentioned, exert an indirect action by producing a shock to the general tissues of the body. Certain class of bodies called emmenagogues and stimuli, have been found to exert specific action on the uterus itself. Alr(e), or Secale cornutum, may be par vegetable, animal, and mineral substances. Different vegetables, such as savin, cantharides, — paradise—
Specific abortives. Ergot of Rye, or Secale cornutum.—This substance has been found, in many instances, to bring on violent action of the uterus at an advanced stage of gestation, or when efforts at parturition had already commenced. There is, however, considerable difference of opinion respecting its emmenagogue properties. According to Dr. Lee, it has no effect, at least in the early stages of gestation, although given in very large doses. (Med. Gaz. xxxv. 10; see also Ed. Med. and Surg. Jour. liii. 27.) Dr. Kluge, of Berlin, found that its properties varied according to whether it was gathered before or after harvest;—in the former case it had an energetic action, while in the latter it was powerless. The properties of the secale are but little known to the vulgar, in this country; and this may account for the fact of our rarely hearing of cases in which it has been criminally administered to pregnant females. Dr. Beatty states that when used in obstetric practice it is liable, by absorption into the system of the mother, which may take place within two hours, to endanger the life of the child. (Dub. Med. Jour., May 1844, 209.) This question was actually referred by the French Government to the Academy of Medicine in 1845, as there was reason to think that under its employment children were frequently born dead. (Ann. d’Hyg. 1846, i. 204. See also Med. Gaz. xlvii. p. 580.) In confirmation of Dr. Beatty’s statement, Drs. M’Clintock and Hardy report, that, out of thirty cases in which it was administered, twenty children were born dead. (Practical Observations, 95.) Dr. Ramsbotham considers that the drug may operate fatally on the child according to the circumstances under which it is administered: but that, unless it excites the expulsive action of the uterus, it has no effect on the child’s system (Op. cit. 319). According to M. Millet, in commenced or imminent abortion, ergot procures a safe and prompt termination. He has never met with a case in which it has injured the child. (Med. Chir. Rev., July 1855, p. 41.) On trials for criminal abortion perpetrated or attempted, a medical witness must therefore be prepared for a close examination on the specific emmenagogue properties of this drug. A case, which occurred a few years since (Reg. v. Calder, Exeter Lent Assizes, 1844), has been reported, with comments on this subject, by Dr. Shapter (Prov. Med. Journal, April 10, 1844). It was alleged on this occasion, that savin, cantharides, and ergot had been respectively given by the prisoner, a medical man, for the purpose of procuring miscarriage. The prosecutrix was a woman of notoriously bad character, and the prisoner was acquitted. There were three medical witnesses, who agreed that savin and cantharides were only likely to occasion abortion indirectly, i.e. by powerfully affecting the system—the view commonly entertained by professional men. Some difference of opinion existed with regard to Ergot. Dr. Shapter stated, in his evidence, that
the surgeon had merely used a speculum to ascertain whether the girl was pregnant, in order to know how to prescribe for her; and it was absurd to suppose that he had ever intended to procure abortion, for this had not followed, and it might have been easily produced by him at any period of pregnancy if prisoner had wished it. The prisoners were acquitted. Admitting the statements of the prosecutrix and prisoner to be correct, it may be remarked that medical practitioners, in the lawful exercise of their profession, do not commonly use a speculum in open fields or coppices to determine whether a female is pregnant or not; and it is a very well-known fact that a speculum is not required for determining the question of pregnancy at all. This case conveys a serious caution to members of the medical profession.

Medicinal substances.—These are perhaps more frequently resorted to for inducing criminal abortion than other means; but they rarely answer the intended purpose, and when this result is obtained, it is generally at the expense of the life of the mother. Mineral poisons have been ignorantly employed for this nefarious object; as arsenic, corrosive sublimate, sulphate of copper, muriate of iron (Reg. v. Wright, Abington Autumn Ass., 1855), and other irritants. Croton oil, gamboge, colocynth, aloes (Henke, Zeitschrift, 1844, ii. 203), hiera picra (see ante, p. 145), elaterium, and other drastic purgatives, have also been used for a similar purpose. Purgatives which produce much straining,—powerful emetics or diuretics, will readily excite abortion in these advanced stages of pregnancy; but these violent medicines fail in their effect at the earlier stages. The substances just mentioned exert an indirect action on the uterus by producing a shock to the general system:—but there is a certain class of bodies called emmenagogues, which have a specific action on the uterus itself. Among these, the Ergot of rye, or Secale cornutum, may be particularly noticed. Other vegetable, animal, and mineral substances, which may be enumerated as having acquired popular repute for procuring abortion, are savin, cantharides, rue, iron filings, squills, grains of paradise (Reg. v. Rushforth, York, Autumn Ass., 1857), pennyroyal, black hellebore, and tansy. In April 1856, a medical man was convicted before the Central Criminal Court of Sydney, of administering extract of belladonna in a suppository, with a view to procure abortion. None of these substances have any influence on the uterus, except in affecting it indirectly by their irritant action on the system. (For an account of the poisonous properties of Savin, see ante, p. 146.) In the coroners' return for 1837–8, there were four cases of the administration of savin and other drugs with the view of procuring abortion. In three of these cases, the mother died undelivered; in the fourth, the child perished.
he did not think the ergot would act unless the natural action of the uterus had already commenced,—a statement supported by a number of authorities. Subsequently to the trial, he collected the observations of many obstetric writers, and so far modified his opinion as to admit that the ergot might occasionally exert a specific action on the uterus, in cases of advanced pregnancy, even when uterine action had not already commenced. His summary on this subject is one of the best which has been published. Dr. Ramsbotham has reported three cases, from which it would appear that the ergot may in some instances exert a direct action on the impregnated and quiescent uterus. In these instances, the females were in or about the eighth month of pregnancy. (Med. Gaz. xiv. 434.) This observation has been fully confirmed by further experience on the use of the drug (Med. Times and Gaz., Jan. 7, 1854, p. 8. See also his Obstetric Med. and Surg. 198.) Dr. J. H. Davis believes that it is a specific excitant of uterine action, and points out the cases in which, in his opinion, it may be safely employed. (Lancet, Oct. 11, 1845, 393.) In a case in which, owing to distortion of the pelvis, it was necessary to bring on labour six weeks before the full period, Mr. Raynes found that ergot in the form of infusion in repeated doses excited the action of the uterus, and delivery was accomplished within fifty-eight hours of the taking of the first dose. The uterus was in a quiescent state before the medicine was given to the patient. (Med. Times and Gazette, March 14, 1857, p. 260.) Mr. Whitehead, who has had considerable experience on this subject, has found that its action is very uncertain. In a case under his care, that of a woman with deformed pelvis, it was considered advisable to procure abortion in the fifth month of pregnancy; the ergot alone was employed, and at first with the desired effect. It was given in three successive pregnancies; and in each instance labour-pains came on after eight or ten doses had been administered, and expulsion was effected by the end of the third day. It was perseveringly tried in a fourth pregnancy in the same female, and failed completely. (On Abortion, 254.) It also failed in a case in the hands of Dr. Oldham. (Med. Gaz. vol. xliv. p. 49.) Nevertheless, the balance of evidence is decidedly in favour of its specific action, as a direct uterine excitant; and, according to Dr. Griffiths, this is so well known to the inhabitants of the United States, that it is in very frequent use as a popular abortive. Perhaps the differences which have been observed in its action may have depended on the quality of the drug as well as on the period at which it was administered. Admitting that the uterus is subject to periodical excitement, corresponding to the menstrual periods, it is probable that the action of the ergot may be more powerfully abortive at these than at other times. The reader will find a large collection of cases, illustrating the properties of this drug, in Wibmer (Arznei-
mittel und Gift, ii. 80: Sphacelia segetum. See also Pereira, Mat. Med. vol. ii. part 1, p. 102.)

The form and characters of the ergot in mass are too well known to professional men to require description. It is black on the outside and reddish-white within, having a soft rough fracture. When the powder is rubbed with a solution of potash it evolves a fishy odour, and the solution acquires a dingy red colour. In the form of tincture, the only test is the odour, which, however, may be concealed by other odours.

Savin. Oil of savin.—This vegetable substance possesses great popular repute as an abortive. In a case which I was required to investigate in 1845, it was a question whether savin, which had been taken in the state of powdered leaves, and had caused the death of a woman, exerted any specific action on the uterus to induce labour. The reply was given, that, in large doses, it acted only indirectly as an abortive by its irritant properties. (See Med. Gaz. xxxvi. p. 646.) It is proper to remember, that the infusion is more powerful than the decoction; since the poison, being a volatile oil, is dissipated by long boiling. Savin is, however, commonly taken or administered in the form of powder. In a case tried at the Cornwall Lent Assizes, 1852 (Reg. v. Pascoe), the accused, a medical man, was convicted and sentenced to transportation for administering oil of savin to a female with intent to procure miscarriage. The proof of intent rested partly on medical and partly on moral circumstances. It appeared that the prisoner had given fourteen drops of the oil, divided into three doses, daily—a quantity which, according to the medical evidence at the trial, was greater than should have been prescribed for any lawful purpose. The medicinal dose, as an emmenagogue, on the authority of Christison, is from two to five minima, and, according to Pereira, from two to six drops. The quantity given by the prisoner, although a full dose, was not, therefore, greater than these authorities recommend; and his criminality appears to have rested not so much on the dose given, as on the question whether he knew, or as a medical man had reason to suspect, that the female for whom he prescribed it was pregnant. No medical authority would recommend oil of savin in full doses for pregnant females; and with regard to the existence or non-existence of pregnancy in a special case, medical men are reasonably presumed to have better means of satisfying themselves than non-professional persons. The prisoner's innocence, therefore, rested on the presumption that he implicitly believed what a young woman told him regarding her condition,—that he had no reason to suspect her pregnancy, and therefore did not hesitate to select and prescribe a medicine which certainly has an evil reputation, and is rarely used by practitioners. According to the evidence of the prosecutrix, she informed the prisoner that she had disease of the heart and liver, and that...
more was the matter with her. It is absurd to suppose that oil of savin would be prescribed by a medical man for such a disease as this. The prisoner, on the hypothesis of innocence, must have intended the medicine to act on the uterus, and must have inferred the existence of an obstruction of menstruation from natural causes irrespective of pregnancy. The jury do not appear to have given him credit for such ignorance of his profession, and this probably led to his conviction. There can, it appears to me, be no doubt that the oil was administered with guilty intention. Every qualified practitioner would undoubtedly satisfy himself that a young female, whose menses were obstructed, was not pregnant, before he prescribed full doses of this oil three times a day, or he would fairly lay himself open to a suspicion of criminality. If pregnancy—a frequent cause of obstructed menstruation—were only suspected, this would be sufficient to deter a practitioner of common prudence from prescribing, in any dose, a drug which may exert a serious action on the uterine system. (A report of the case of Mr. Pascoe will be found in the Med. Times and Gazette, April 17, 1852, p. 404.)

The oil of savin is obtained by the distillation of the tops in the proportion of about three per cent. It has a yellowish colour, and the peculiar terebinthinate odour of the plant, by which alone it may be recognised. It may be separated from the contents of the stomach by agitating them in a bottle with its volume of ether, in which the oil is very soluble. The ether may be afterwards removed by distillation. The oil of savin forms a turbid mixture with alcohol (826). When treated with its volume of sulphuric acid, it acquires a dark red-brown colour, and when this mixture is added to distilled water, a dense white precipitate is separated. The odour is the best test.

Oil of tansy.—Dr. Hartshorne, the American editor of this work, states that in the United States the oil of tansy (Tanacetum vulgare) has acquired the character of a popular abortive, and has caused death in several instances. In England this oil and the herb have been chiefly employed for the purpose of expelling worms. Dr. Pereira quotes a case in which half an ounce of the oil proved fatal. The symptoms were spasms, with convulsive movements and impeded respiration. No inflammation of the stomach or bowels was discovered upon dissection. (Mat. Med. vol. ii. pt. ii. p. 26.) The cases referred to by Dr. Hartshorne, are, 1. A tea-spoonful of the volatile oil was taken by a girl in mistake for the essence. She complained of giddiness, and became insensible in ten minutes. Convulsions came on, with frothing at the mouth, difficult respiration, and irregular pulse, and she died in one hour after taking the oil (Amer. Jour. Med. Sci., July 1852, p. 279.) 2. The second case occurred to Dr. Dalton, and is reported by him in the same journal for January 1852, p. 136. A healthy-looking girl, at 21, took eleven drachms
of oil of tansy about six hours after a hearty dinner. She was found insensible and in convulsions, soon after she must have taken the drug. She died in three hours and a half. A strong odour of tansy was observed in the breath before death, and on inspection in the peritoneal cavity, stomach, and even the interior of the heart. The uterus contained a well-formed Fetus about four months old, which did not, either in itself or its membranes, present any evidence of having been disturbed. 3. In a third case (reported in Amer. Jour. Med. Sci. for May, 1835), a woman but a few weeks pregnant took half an ounce of the oil, and did not entirely lose her consciousness until three quarters of an hour had elapsed, although she was convulsed at intervals before that time. She died without abortion being produced, within two hours after taking the poison. These facts show, that while oil of tansy possesses no specific action on the uterus as an abortive, and does not even affect this organ or its contents by sympathy, it is capable of acting as a powerful poison on the brain and nervous system, and of destroying life rapidly.

The oil would be easily recognised either before or after distillation of the contents of the stomach, by its peculiar and penetrating odour. Ether may be employed for its separation.

It is remarkable, that the action of the most powerful mineral irritant poisons have sometimes failed to affect the gravid uterus. In July 1845, a case was referred to me for examination by Mr. T. Carter, of Newbury, in which a female, aged twenty-two years, who had passed the fifth month of pregnancy, took a large dose of arsenic, and died in less than seven hours, having suffered from severe vomiting and purging during that time: yet abortion did not take place! In reference to the medicinal use of mercury, it may be proper to state, that Dr. Salomon has reported two cases, in which premature delivery appeared to follow the mercurialization of the system. (Casper’s Wochenschrift, June 1845; Med. Gaz. xxxvi. p. 658.)

Local applications.—In a case which occurred in France, it was proved that abortion had been caused by the injection of some corrosive and irritating substance into the vagina. The female genitals, as well as the abdominal viscera, were found in a high state of inflammation. (Med. Gaz. xxxvii. 171.) This is a very unusual mode of perpetrating the crime; but it is one which can hardly escape detection. An analysis of the tissues might be required, to determine the nature of the substance used. It would appear from a trial which took place at the York Summer Assizes, 1853, that this mode of attempting to produce criminal abortion has been the subject of a prosecution in this country. It was established by the evidence that some liquid was injected into the vagina by a syringe: but there was no proof of the nature of this liquid, and as it was not proved that.
it was of a noxious nature, the learned judge who tried the case directed an acquittal. (Lancet, July 23, 1853, p. 89.)

**Signs of abortion.**—These have been already fully considered in a previous chapter. (See Delivery, ante, pp. 551 and 553.) The examination may extend to the female either living or dead. In the former case, there will be some difficulty if the abortion have occurred at an early period of gestation, and several days have elapsed before the examination is made. In the latter case the investigation is not always free from difficulty. One fact here requires to be especially noticed. It is now believed by many physiologists, that menstruation is a state, in some measure, vicarious to conception; and the appearances presented by the generative organs during the menstrual period are somewhat similar to those which are observed after conception in its early stage. Mr. Whitehead remarks, that in persons who have died while the menses were flowing, the uterine walls have been found thickened and spongy; and the mucous lining more or less turgid and suffused. The cervix and labia of the uterus were tumid, the orifice open, and the vaginal membrane and clitoris involved in the increased action. One of the ovaries was found larger and more congested than ordinary, presenting evidences of the recent escape of an ovum. (On Abortion, 196.) Unless these facts be attended to, the examiner may form a very erroneous opinion respecting the chastity of a deceased female.

**Feigned abortion.**—For various motives, into the consideration of which it is unnecessary to enter, a woman may charge another with having attempted or perpetrated the crime of abortion. Such a charge is not common, because, if untrue, its falsity is easily demonstrated. A young woman, admitted into Gay's Hospital in April 1846, charged a policeman, who, according to her statement, had had forcible intercourse with her, with having given her some substance to produce abortion, and with having subsequently effected this mechanically. She was not examined until nearly two months after the alleged perpetration of the crime, when Dr. Lever found that there was no reason to believe she had ever been pregnant. This was a case of feigned abortion. When charges of this serious kind are brought forward, they are always open to the greatest suspicion, unless made immediately after the alleged attempt, as it is then only that an examination can determine whether they be true or false. If so long delayed as in this instance, without any satisfactory reason, the presumption is that they are false.

**Legal relations.**—The English law relative to criminal abortion is laid down in the statute 1 Vict. c. lxxxx. s. 6. By it, capital punishment, which formerly depended on the proof whether the female had quickened or not, is abolished. The words of the statute are as follows:

> "Whosoever, with the intent to procure the miscarriage of any
woman, shall unlawfully administer to her, or cause to be taken by her, any poison or other noxious thing, or shall unlawfully use any instrument or other means whatsoever, with the like intent, shall be guilty of felony, and being convicted thereof, shall be liable, at the discretion of the Court, to be transported beyond the seas for the term of his or her natural life, or for any term, not less than fifteen years, or to be imprisoned for any term not exceeding three years."

It has not been decided whether, under this statute, a woman could be tried for abortion attempted on herself. The consent, or even the solicitation of the female to the perpetration of the crime does not excuse an offender. The crime would never be attempted without the consent of the woman; and, therefore, to admit this consent as a sufficient justification, would be equal to an entire abrogation of the law. The means must have been used with the intent to procure the miscarriage of the woman,—a point which will be sufficiently established by a plain medical statement of the means employed. Supposing that a drug has been used, the witness will have to state whether it be "a poison, or other noxious thing;" for this must be proved, in order that the prisoner should be convicted of the crime. I must refer the reader to what has been said elsewhere (ante, p. 4), in order that he may be able to judge how far the substance administered would fall under the description above given. Whether the substance administered would or would not have the effect intended, i.e. of inducing abortion, is perfectly immaterial. Some uncertainty may exist as to the strict meaning of the word noxious:—all will allow that the word implies something injurious to the system: but a difference of opinion may arise among witnesses with respect to its application to the substance under discussion,—as, for example, with respect to rue or savin. A substance must be regarded as injurious to the system, or noxious, either according to the form, quantity, or frequency with which it is administered. Savin and rue are irritant; and become noxious when given in large doses, or in small doses frequently repeated. (Ann. d’Hyg. 1838, ii. 180.) Aloes and castor-oil are innocent when taken in small doses; but they acquire noxious or injurious properties when administered frequently, or in large quantity, to a pregnant female. To confine the term noxious, therefore, to what is strictly speaking a poison, would be giving a latitude to attempts at criminal abortion, which would render the law inoperative. (See the case of Reg. v. Stroud, Abingdon Sum. Ass. 1846.) The small quantity of the substance taken at once does not affect the question, provided the dose be frequently repeated. A case in which I was consulted by Mr. Reynolds (a former pupil) was tried at the Exeter Winter Assizes, 1844. Two powders, weighing each one drachm, were prescribed by the prisoner,—one consisted of colocynth, the other of gamboge, and with them was half an ounce.
of a liquid (balsam of copaiba). They were to be mixed together, and a fourth part to be taken four mornings following. Mr. Reynolds said, in answer to the question whether such a mixture was noxious or injurious, that each dose would be an active negative, and might thereby tend to produce abortion. One dose would not be productive of mischief in a healthy countrywoman, but its frequent repetition might lead to serious consequences. In a trial which took place at the Norwich Lent Assizes, 1846 (Reg v. Whisher), it was proved that the prisoner had caused to be taken, by the prosecutrix, a quantity of white hellebore, in powder, for the purpose of procuring abortion. One medical witness said he considered hellebore to be noxious to the system, but he knew of no case in which it had produced death; and under these circumstances he did not consider himself justified in calling it a poison. Another medical witness declared that in his opinion it belonged to the class of poisons. The judge, in summing up, told the jury that that was to be regarded as a poisonous drug which, in common parlance, was generally understood and taken to be such; and he thought the evidence sufficiently strong to bring hellebore within the meaning of the statute. The jury found the prisoner guilty, alleging that in their belief white hellebore was a poison. (Med. Gaz. xxvii. 830.) The only circumstance calling for remark in this case is, that any doubt should have been entertained by a medical practitioner respecting the poisonous properties of white hellebore. It is a powerful vegetable irritant, and has caused death in several instances; yet on this occasion it appears to have been admitted to be noxious, but not poisonous!

In reference to the proof of this crime, it is not required, under the circumstances, that any specific injury should have been done to the woman, or that abortion should have followed, in order to complete the offence. There is every reason to believe that this crime is very frequent; but its perpetration is secret. Applications are continually made to druggists by the lower class of people, for drugs for this purpose: the applicants appear to have no idea of the criminality of the act. (See, in reference to the frequency of this crime, a paper in the Medical Gazette, xlvii. p. 487; also Med. Times and Gaz., Nov. 21, 1857, pp. 524, 537.)

On inducing premature labour. Medical responsibility.—It may be proper to offer here a few remarks upon the practice of inducing premature labour, which is adopted by some members of the profession, in cases in which there happens to be great deformity of the female pelvis. This practice has been condemned as immoral and illegal; but it is impossible to admit that there can be any immorality in performing an operation to give a chance of saving the life of a woman, when, by neglecting to perform it, it is almost certain that both herself and the child will perish (See, on the morality, safety, and utility of the practice, Rans-
botham's Obstet. Med. p. 315.) The question respecting its illegality cannot be entertained; for the means are administered or applied with the bonâ fide hope of benefitting the female, and not with any criminal design. It is true that the law makes no exception in favour of medical men who adopt this practice, nor does it in the statute of wounding make any exceptions in favour of surgical operations; but that which is performed without evil intention, would not be held to be unlawful. The necessity for the practice ought to be apparent;—thus, for instance, it should be shown that delivery was not likely to take place naturally, without seriously endangering the life of a woman. It is questionable whether, under any circumstances, it would be justifiable to bring on premature expulsion, merely for the purpose of attempting to save the life of a child, since the operation is necessarily accompanied with risk to the life of the mother. The grounds upon which many eminent authorities have objected to this practice, are:—1. That there are few cases in which parturition, if left to itself, might not take place at the full period.—2. The toleration of the practice might lead to great criminal abuse.—3. It is attended with danger to the mother and child. It is undoubtedly true, that parturition will sometimes take place safely at the full time, even when the deformity of the pelvis is apparently so great, as to lead many accoucheurs to suppose natural delivery to be utterly impossible. Dr. Liburn has reported the case of a female who laboured under great deformity of the pelvis, but who was twice delivered in safety, and the child survived. (Med. Gaz. xix. 933.) It is, therefore, not improbable that many cases of the kind are prematurely treated, which, if left to themselves, would probably do well without interference. Hence a cautious selection should be made; because the operation is necessarily attended with some risk,—it does not insure safety to the woman and child. All that we can say is, that, according to general professional experience, it places her in a better position than she would be in, if the case were left to itself. It appears to me that if a practitioner resolves upon performing an operation of this kind, he should hold a consultation with others; and, before it is performed, he should feel well assured that delivery cannot take place without greater risk to the life of the mother, than the operation itself would create. These rules may not be observed in practice; but the non-observance of them is necessarily attended with some responsibility to a practitioner. In the event of the death of the mother or child, he exposes himself to a prosecution for a criminal offence, from the imputation of which even an acquittal will not always clear him in the eyes of the public. If the child were born alive, and died merely as a result of its immaturity, this might give rise to a charge of murder or manslaughter. Within a recent period several practitioners have been tried upon charges of
criminal abortion,—whether justly or unjustly it is not necessary to consider; but one fact was clear, they neglected to adopt those simple measures of prudence, the observance of which would have been at once an answer to a criminal charge. Because one practitioner may have frequently and successfully induced premature labour without observing these rules, and without any imputation on his character, this cannot shield another who may be less fortunate. A charge is only likely to arise when a man has been unfortunate; and the responsibility of one operator cannot be measured by the success of others.

A case occurred at Portsmouth in 1848, in which a female died from haemorrhage, which took place during an attempt to induce premature labour. A small aperture was discovered after death in the left common iliac artery, and more than a pound of blood had been effused. This was ascribed to a thinning of the coats of the artery, and not to a puncture of the vessel during the operation. (See Lancet, July 22, 1848, p. 107.) For some judicious remarks on the induction of premature labour, by Dr. Radford, see Med. Gaz. xlvii. p. 583.

Is proof of pregnancy necessary? — A female may imagine that she is pregnant, when she is labouring under ovarian dropsy, or other uterine or abdominal disease. Under this mistaken view, an attempt may be made by another, also deceived as to her condition, to procure abortion; and the proof of the corpus delicti will here rest upon the medical evidence. The pregnancy of the female is not alluded to in the recent statute:—the words being,—

"procure the miscarriage of any woman." These might at first sight appear to include the state of pregnancy; but the term "miscarriage" has a much more extensive meaning than this in a popular sense. The question in reference to the necessity of the proof of pregnancy has been hitherto variously decided by our judges. A case was tried on the Midland Circuit, July 1838, in which a medical practitioner was charged with this crime. Chief Justice Tindal held, that without positive proof of the woman's pregnancy, which, however, was distinctly alleged in the indictment, a conviction could not take place. In this instance, the woman herself denied her pregnancy, and there was no evidence in support of it. The judge directed an acquittal. On the Spring Circuit of the same year, a man was tried at Lincoln, on a charge of administering a certain noxious drug to a female, with the intent to procure a miscarriage. The jury stated their opinion, that the girl was not pregnant when she took the drug. In this case the prisoner was discharged. More recently, in the case of Reg. v. Haynes (Cent. Crim. Court, 1843), the prisoner was found guilty of administering a drug with intent to procure abortion, when the woman was clearly proved, by the dissection of her body, not to have been pregnant.

The question whether the state of pregnancy be or be not an
essential condition in reference to charges of criminal abortion has, however, been decided in the negative, on a conference of the judges, in the case of the Queen v. Goodall (Notts Lent Ass. 1846). The deceased, believing herself to be pregnant, applied to the prisoner to procure abortion by puncturing the membranes. Some instrument was used for this purpose; and deceased, who had laboured under chronic cough, died, as it was alleged, from the maltreatment of the prisoner. The body was inspected, and it was clearly proved that deceased was not pregnant. The defence was—a want of proof that the prisoner believed deceased to have been pregnant, and therefore that the mechanical operation alleged to have been performed might have been resorted to for the purpose of relieving her from other symptoms under which she was suffering. The most important point urged in the defence, however, was, that the crime of abortion was not complete without pregnancy; and therefore the prisoner could not be convicted under the statute. A verdict of guilty was returned, but Coltman J. on this occasion reserved the question for the consideration of the judges. At the following Assizes, Coleridge J. delivered judgment. The judges held that the conviction was right. (Med. Gaz. xxxvii. 831.)

It is, therefore, established by this decision, that a person believing a female to be pregnant, and perpetrating on her an act which would amount to an attempt at abortion if the female were really pregnant, may be equally convicted under the statute. Hence the words "procure the miscarriage of any woman" do not necessarily include proof of pregnancy, nor can the term "miscarriage" be considered to apply only to a woman in the pregnant condition. It is remarkable that the same question arose under the old statute, 43 Gco. III. c. 58, in which the words "being with child" were used; yet even there Lawrence J. held that pregnancy was not necessary to be proved, and that the crime of abortion would be complete although the woman was not pregnant. (Reg. v. Phillips, Paris, Med. Jur. iii. p. 88.)

An attempt made on non-pregnant females should certainly be treated as a crime, and punished accordingly; but, medically speaking, abortion presupposes pregnancy; and if a woman be not pregnant, the carrying out of the intent by the accused is a physical impossibility; yet, as the law is now expounded, a person may be convicted of attempting to procure miscarriage in a female who cannot miscarry. It would appear that according to the law of France proof of pregnancy is not essential. Dr. Bayard relates a case in which a woman was convicted, in 1846, of an attempt to induce abortion in a female who was subsequently proved not to be pregnant, but to be labouring under ovarian disease. The prisoner was sentenced to eight years' imprisonment. (Ann. d'Hyg. 1847, i. 466.)
Abortion of monsters.—Would the law apply if the child were dead in the uterus, or if it were a monster without human shape? The symptoms indicative of the death of the child in utero have been elsewhere stated (ante, p. 430). The death of the child subsequently to the attempted abortion might perhaps be deduced as corroborative evidence of the crime; but, even if it were dead at the time of the attempt, a conviction would follow. (Reg. v. Goodall, supra.) It cannot be doubted that the expulsion of a dead child would come under the popular signification of a miscarriage; and if the words were strictly interpreted, the prisoner might be convicted whether the child were living or dead, for it has been already said, that it is not necessary that any abortion should have taken place. With respect to monsters, the question actually arose in a case tried at Drôme, in France, in 1841. (Gaz. Med., Juillet 1841; also Brit. and For. Rev. xvi. 563.) A girl was accused of procuring abortion. The aborted fetus of about the sixth month was acephalous, and there was no vertebral canal for the spinal marrow. Other organs were also deficient or imperfectly formed. The medical witnesses declared that it had never breathed, and that its life had ceased with gestation. On the upper part of the body was a wound, which had been produced by a pointed instrument, probably just before it was expelled. This they thought had caused death. The counsel for the prisoner contended that this could not be regarded as a case of criminal abortion, owing to the monstrosity of the offspring; and the jury acquitted her. As proof of pregnancy is no longer required, monstrosity in the fetus should make no difference in the nature of the crime.

Extra-uterine conceptions.—Would the law apply to cases of extra-uterine pregnancy? There can be no doubt that the crime of abortion would apply to cases of this description; and a person would be equally amenable for the attempt, whether the fetus were in the uterus or in the Fallopian tube. The symptoms of extra-uterine pregnancy, especially of the tubal kind, are very similar to those of ordinary pregnancy; they are not to be distinguished from them in the early stages (see Med. Gaz. xxxvi. 103).

Abortion of moles and hydatids.—The use of the word miscarriage in the statute, without any explanation of the meaning assigned to it, might, but for the decision in Reg. v. Goodall, have created some difficulty on trials for abortion. In a popular sense (and here a popular appears to have been purposely selected in preference to a medical term), miscarriage signifies the violent expulsion, not merely of a child, but of moles, hydatids, and other diseased growths, or even of congloba of blood. In these last-mentioned cases, the woman is not actually pregnant, although she and the prisoner may imagine that she is. The decision in Reg. v. Goodall shows that it is unnecessary to speculate
on this subject. Whether the uterus contain these morbid growths, or whether it be in the virgin state, the party who has used the means with intent may still be convicted of an attempt to procure abortion.

**Chemical evidence. Blood in abortion. Liquor amnii.**—In the event of an abortion having taken place, stains produced by blood or by the waters (liquor amnii) may be found on the linen of a female, and a practitioner may be required to say whether these stains are of a nature to throw any light upon the perpetration of the crime. A female who has aborted, may allege that the stains are those of the menstrual discharge. Speaking generally, there is no practical distinction between menstrual and other blood (see ante, p. 315). The menstrual blood contains less fibrin; it is commonly acid, from admixture with the mucous discharges, and it is found to present under the microscope epithelial scales, or cells from the mucous membrane. These scales or cells belong to the conical or pyramidal variety, and have at their free extremities or bases, ciliary processes. Not much reliance can be placed upon their discovery, since the mucous membrane of the organs of respiration is lined with similar cells. Hence, expectorated blood might be mistaken for menstrual. Cells of a similar shape line the whole of the mucous membrane from the stomach to the anus. The blood of piles might thus be confounded with menstrual blood. The blood discharged in abortion will present the usual characters of blood, elsewhere described (ante, p. 305); but it may be diluted by the waters simultaneously discharged. This question received the special attention of the French Academy a few years since, in reference to the crime of abortion, and the report made was to the effect that in the present state of science there was no certain method by which the blood of menstruation could be practically distinguished from the blood discharged from a female in a case of abortion or infanticide (Ann. d’Hyg. 1846, i. 181). In a more recent case, M.M. Devergie and Chevallier were required to state whether certain stains on the dress of a female supposed to have aborted, were or were not caused by the waters (liquor amnii). A chemical analysis merely revealed the presence of an albuminous liquid. The most elaborate experiments satisfied the reporters that neither by the odour, nor by any other process, could the liquor amnii, dried on linen, be identified. (See Ann. d’Hyg. 1852, ii. 414.)
BIRTH. INHERITANCE.

CHAPTER LI.

Live birth in civil cases.—The law of England has not defined the meaning of the term Birth, in reference to civil jurisprudence; but if we are to be guided by the numerous decisions which have been made on trials for infanticide, it must be regarded as signifying "the entire delivery of a child," with or without its separation from the body of the mother (ante, p. 468, 523. See also Chitty, Med. Jur. 412). So long as an infant remains in the uterus it is said in law to be "in ventre sa mère;" but it is legally supposed to be born for many purposes. (Blackstone's Comm. i. 130.) A child in the womb may have a legacy or an estate made over to it,—it may have a guardian assigned to it; but none of these conditions can take effect unless the child be born alive. So the foetus may be made an executor; but it is very properly provided that an infant cannot act as such until it has attained the age of seventeen years! The Roman and English systems of law apply the same term, venter, to the unborn child: when born dead it is called abortus, abortion; when alive, partus, infans, infant.

Date of birth.—Medical evidence has occasionally been demanded in Courts of law respecting the actual date of birth of individuals, in cases in which a period of a few days, hours, or even minutes, was required to prove the attainment of a majority,—and therefore a legal responsibility for the performance of civil contracts into which the parties had entered, either
knowingly or ignorantly, when minors. Some such cases have
been decided by the evidence of the accoucheur himself,—others,
when the accoucheur was dead, by the production of his case-
books; and it is worthy of notice that the strictness and punctu-
ality of some medical practitioners in making written memo-
randa of cases attended by them, have in more than one instance
led to a satisfactory settlement of such suits, and the avoid-
ance of further litigation. The proof of the date of birth is
also of considerable importance in certain cases of contested
legitimacy.

The most important medico-legal questions connected with this
subject, are those which arise in contested suits relative to suc-
cession, or the inheritance of property. A child which is born
alive, or has come entirely into the world in a living state, may
by the English law inherit and transmit property to its heirs,
even although its death has immediately, and perhaps from mor-
bid causes, necessarily followed its birth. Should the child be
born dead, whether it died in the womb or during the act of birth,
it does not acquire any civil rights: for it is not regarded as a
life in being, unless it manifests signs of life after it is entirely
born. Some have considered that partial birth, provided the child
be living, should suffice to confer the same rights on the offspring
as the proof of entire birth. The following case has been adduced by
Dr. Locoek in support of this view, although the question here
was rather in reference to the actual date of birth, than to the
acquisition of civil rights therefrom:—the principle is, however,
the same. On a Saturday evening a lady was in labour with her
first child. The head and one arm were born two or three
minutes before a neighbouring clock struck twelve. There was a
cessation of pain for several minutes, during which time the child
cried and breathed freely. The rest of the body was not expelled
until full five minutes after the same clock had struck twelve.
Was this child born on the Saturday or on the Sunday? Cer-
tainly the birth was not completed until the Sunday:—the child
was still partly within the mother; the circulation was still kept
up through the umbilical vessels: "but," continues Dr. Locoek,
"I gave my opinion that the child was born on the Saturday. I
considered that the child had then commenced an independent
existence. The fetal life had then to all intents and purposes
ceased; and respiration—a function incompatible with the con-
dition of a fetus—had commenced. The navel-string will, it is
ture, go on pulsating for many minutes after an infant has been
brought completely into the world crying and kicking, unless it
be compressed artificially; and yet no one will say that the child
in such a case is not born until we choose to take the trouble to
tie the navel-string. The child would not have been damaged if
it had remained for hours, or even days, with merely its head
and arms extruded; it could have been fed in this situation." (Med.
Gaz. xii. 636.) However reasonable, medically speaking, this view may appear, a medical jurist must shape his evidence according to what the law demands. It has been elsewhere stated (Infanticide, ante, p. 468), that our judges have distinctly laid down the law, that no child can be considered to be legally born until the whole of its body has come entirely into the world. This is in relation to criminal jurisprudence, in which case, if in any, the rule should be relaxed; because its relaxation would tend to punish the wilful destruction of living infants partially born. This child could not, therefore, have been born on the Saturday, because the law does not regard partial birth as entire birth; and respiration and birth are not synonymous terms. Supposing this child to have died before its body was entirely extruded, it could not be said, even medically, that it was born alive; and certainly it could not be considered, according to the present state of the law, to have acquired the rights of a child born living. The reasonableness of the opinion that partial birth should suffice for all the legal purposes of entire birth, is an entirely distinct question and one over which a medical witness has no sort of control. Whatever apparent injustice may be done by adhering to this rule in respect to the civil rights of persons, there is no doubt that the evil is really of great magnitude in relation to criminal jurisprudence; for it would appear from the present state of the criminal law, that partially born children, although alive and healthy, may be wilfully destroyed with impunity (ante, p. 323).

On the other hand, some difficulty might arise in civil cases, if the bare extrusion of a part of the body sufficed for all the legal purposes of entire birth. It might become a casuistical question, as to how much of the body should be in the world, in order to constitute legal birth; for there is no reason why, in a medical view, the extrusion of the head and shoulders should constitute birth any more than the extrusion of a hand or a foot. If it be said that the act of respiration should be combined with partial extrusion, this would be unjust; because a child is alive, — its heart is evidently pulsating, and its blood circulating, as freely before the act of respiration as afterwards. Besides, it is admitted that children may be born alive and live for some time without respiring; and this want of respiration is no objection to these children being considered living in law. A case will be related hereafter (p. 592, post) in which a child was legally pronounced to have been born alive, although it had certainly not respired; and that a child may manifest life for a certain time without leaving in its body any evidence of respiration is clear from a case reported at p. 451, ante. If, then, proof of respiration be not demanded in cases of entire, it could scarcely be required in cases of partial birth. In the event of partial being treated as synonymous with entire birth, there would be no end to litiga-
SIGN OFS OF LIVE BIRTH

tion; and medical opinions would vary in every case. It is
doubtful whether, under such circumstances, the law could be
administered with any degree of certainty or impartiality. Ad-
mitting, then, that a child must be entirely born, in order that it
should acquire civil rights, it will next be necessary to examine the
medical proofs required to show that it has been born alive.
The question here is different from that of live birth in reference
to child-murder. We must presume that a practitioner is present
at a delivery in which a child is born in a doubtful state, or
where its death speedily follows its birth. The civil rights of
the child and its heirs will depend upon the careful observation,
made by the practitioner, of the circumstances attending the
delivery. It is proper that he should note when the birth is
completed by the body of the child being entirely out of the
body of the mother. Children born at or about midnight are
thus liable to have the date of birth wrongly registered; and
the legal difference of twenty-four hours, which a few seconds or
minutes may make, may hereafter affect their own rights if they
survive, or those of others if they die. The birthday of the late
illustrious Duke of Wellington was entered in the Parish
Register as the 30th of April 1769, while there is abundant
evidence for fixing it on the 1st of May. In fact, he was born
just after twelve o'clock in the night between the 30th of April
and the 1st of May. Nothing can be more simple than for an
accoucheur to fix the true date, not by the hour at which labour
commences, but by the time at which it is completed.

Signs of live birth independently of respiration or crying.—The
visible respiration of a child after its birth, or as it may be mani-
fested by its crying, is an undisputed sign of its having been
born alive; but, as it has just been stated, a child may acquire its
civil rights, although it may be neither seen to breathe nor heard
to cry. The pulsation of a child's heart, or even the spasmodic
twitching of any of the muscles of the body, has been regarded
as a satisfactory proof of live birth. The latter sign has been
judicially so pronounced, — a fortiori, therefore, the motion of a
limb will be considered sufficient legal evidence in an English
Court of law, of life after birth. It is to be observed, that the
length of time during which these signs of life continue after a
child is born, is wholly immaterial: — all that is required to be
established is, that they were positively manifested. A child
which survives entire birth for a single instant, acquires the
same civil rights as if it had continued to live for a month or
longer. These facts will be better understood from the following
case (Fish v. Palmer), which was tried in the Court of Exche-
quer in the year 1806: — The wife of the plaintiff Fish, who
was possessed of landed estate in her own right, died about ten
years previously to the trial, after having given birth to a child
which was supposed at the time to have been born dead. In
consequence of the plaintiff's not having had a living child (as it was assumed) by his marriage, the estate of the wife was claimed and taken by the defendant Palmer, her heir at law, the husband being obliged to surrender it under these circumstances. From information derived many years subsequently from some women who were present at the delivery of the wife, the plaintiff was led to think that the child had not been born dead, and that the estate had been improperly surrendered. The action was therefore brought to contest the possession ten years after the death of the wife; and it lay with the plaintiff to prove his allegation—that the child had been born living. Dr. Lyon, the accoucheur who attended the plaintiff's wife, had died some time before the trial; but it was proved that he had declared the child to have been living an hour before it was born, that he had directed a warm bath to be prepared, and when the child was born, gave it to the nurse to place in the bath. The child neither cried nor moved after its birth, nor did it manifest any signs of active existence: but the two women who placed the child in the bath swore that, when it was immersed, there appeared twice, a twitching and tremulous motion of the lips. They informed the accoucheur of this, and he directed them to blow into its throat; but it did not exhibit any further evidence of life. The principal question on the trial was:—Whether this tremulous motion of the lips was sufficient evidence of the child having been born alive? The medical witnesses differed. Dr. Babington and Dr. Haighton gave their opinion that, had the vital principle been extinct, there could have been no muscular motion in any part of the body;—therefore the child had, in their opinion, been born alive or manifested some evidence of life after its entire birth. Dr. Denman gave a contrary opinion; he contended that the child had not been born alive, and attempted to draw a distinction between uterine and extra-uterine life. He attributed the motions of the lips after birth to the remains of uterine life. The jury, however, under the direction of the Court, did not adopt this view of the case:—they pronounced the child to have been born living; and, by their verdict, the plaintiff recovered an estate of which he had been for ten years deprived.

From the result of this case, it would appear that the law does not recognise the distinction attempted to be drawn by Dr. Denman, between what he called uterine and extra-uterine life. A distinction of this kind appears to be purely artificial;—respiration is commonly set down as a mark of extra-uterine life: but a child may breathe and die before it is born, or it may be entirely born and manifest indubitable signs of life, without respiring. Respiration, therefore, is properly regarded by the English law as only one sign of life,—the proof of the possession of active and vigorous life is not absolutely required. It cannot be admitted physiologically that any tremulous motion in the muscles could
Evidence of Live Birth in Civil Cases.

Ever take place spontaneously in a really dead body; and the spasmodic motion of the lips differs only in degree from the active motion of a leg or an arm. If a certain quantity of life, so to term it, were required to be proved, instead of the bare fact of its presence or absence, the most subtle distinctions would be continually drawn:—thus, it might be contended that unless a certain degree of respiration had taken place, it should be assumed, contrary to well-known facts, that the child had been born dead. Non-professional persons might be easily deceived as to the fact of respiration in these feeble subjects, and an examination of the body after death would not always remove the doubt, for respiration so varies in degree, that a child may breathe and survive its birth many hours, scarcely receiving any air into its lungs (ante, p. 450); but a person is not so likely to be deceived about the motion of an arm or a leg. The power by which a limb is moved is the same as that by which the intercostal muscles are moved in the act of respiration. It has been objected to this view of the case, that the motion described may have been the mere remains of muscular irritability, and not a sign of actual life. I am unable to perceive the force of this objection. Irritability, as manifested by spontaneous motion, is not a property of dead matter; and the remains of irritability must, physiologically speaking, be regarded as the remains of life or of a vital power in the muscles. Could any witness have sworn that a child proved to have been living just before birth, and whose lips twice manifested a tremulous motion after its birth, was born dead? It appears to me that he would not have been justified in so doing. He would be compelled to admit that such spontaneous contractions are not observed in bodies really dead, and that they are the certain indications of some vital power still remaining. The English law recognises no intermediate state between life and death: and it does not require a certain amount of active life to be manifested, but merely satisfactory proof that there is some sign or some indication of vital power, in the child's body, after it has been brought entirely into the world. Besides, it is forgotten by those who would in these cases restrict the proof of life, that such a restriction would be attended with great injustice; for, morally speaking, the right of a husband to enjoy for life the estate of a wife, should not be made to depend upon the mere accident of a child being born, or of its having survived its birth for a few moments. On these occasions the mere warmth of the body of a child at its birth would not be evidence of life:—the slightest trace of vital action, in its common and true physiological acceptation, such as crying, respiration, motion, or pulsation, observed after entire birth, would, however, probably be deemed by our law a sufficient proof of the child having been born alive. (For a case by M. Marc, somewhat similar, but in
which the medical opinions were opposed to these views, see Ann. d’Hyr. 1832, i. 98.)

In some former editions of this work, it has been stated, upon
the authority of a Scotch medical jurist, that the law of Scotland
required only proof of respiration in order to establish the fact
that a child had been born alive; I am indebted to an eminent
member of the bench in that country for a correction of this
statement. In Scotland, the husband’s right of courtesy, or life-
rent in his wife’s estate, depends on there having been a child
of the marriage born alive, and for the proof of live birth it is
required to be shown, not merely that it had breathed, but that the
child cried after it was born. The last case of this kind came
before the Courts in 1833, and by a majority, their Lordships
adhered to some old dicta in the law, and decided that the only
receivable proof of life in such a case was that the child had
cried. They found, that proof that the child was capable of
motion, and that it had breathed for three quarters of an hour,
was not sufficient to establish life unless the child had cried.
There is reason to believe that, in any future case, this will not
be taken as a precedent. The attainment of greater knowledge
on the nature and the proofs of life from the results of medical
experience and observation, and the fact that these questions
have become more generally known and better understood, will
probably lead to a totally different decision. That there should
not be a power of proving life (when the death of a child takes
place speedily after birth), except by direct proof that the child
had cried, is in truth a view of the matter wholly indefensible.
From what will be presently said (Vagitus uterinus, iniirri) it will
be seen, that the crying of a child is not necessarily a sign of
live birth; while the fact that it breathes and moves after birth,
although from accidental circumstances it may not cry, is an
exceptionable evidence of its having been born alive.

Vagitus uterinus.—Let us suppose that the evidence of a child
having been born alive is stated to be, that it was heard to cry:
— it may be a question for a medical witness in cross-examina-
tion whether this is to be taken as an absolute proof of live birth.
The answer must be in the negative, because a child may cry
before its body is entirely born:—or it may be what is called
vagitus uterinus,—a uterine cry after the rupture of the mem-
branes. (See ante, Infanticide, p. 465.) It is quite certain that
a child may breathe without crying, but it cannot cry without
breathing; yet neither the crying nor the breathing is a neces-
sary proof that the child was born alive. As in all cases of this
description there must be eye-witnesses, whether professional or
not, the evidence will not rest solely upon a mere medical pos-
sibility of the occurrence of such a cry before birth; and proof
will be required of the crying of the child after it was born.
There are two cases in which the determination of the momentary existence of children after birth becomes of importance in a legal point of view. These are cases involving the questions of Possessio Fratris, and Tenancy by Courtesy.

Possessio fratris.—In the event of a man twice married dying intestate, and leaving a daughter by each marriage, his estate would be equally shared by the daughters of the two marriages: but if we suppose that there is a son of the second marriage, born in a doubtful state, the legal effect of this child momentarily surviving birth, manifested by some slight sign of life, would be to disinherit the daughter of the first marriage entirely, and transfer the whole of the estate to the daughter of the second marriage, she being sister to the male heir, while the daughter of the first marriage is only of half blood. The determination of this point, which does not often occur, must rest essentially upon medical evidence, when there is a want of clear proof of life after birth. (See Amos, Med. Gaz. i. 738.)

Tenancy by courtesy.—This signifies, according to Blackstone (Com. ii. 426), a tenant by the Courts of England. The nature of this tenancy has been already explained. (See the case of Fish v. Palmer, ante, p. 592.) If a married woman, possessed of fee simple estate, die, the estate passes from the husband to her heir at law, unless there has been a child born living of the marriage, in which case the husband acquires a life-interest in the property. The only defence of this singular custom is, that it is of great antiquity. An unsuccessful attempt was made a few years since to substitute for it the reasonable provision, that the marriage should entitle the husband to a right, which he can now only acquire by the fulfilment of certain accidental conditions. Incurable sterility, a protracted labour, deformity in the pelvis of the wife, or the necessary performance of craniotomy on a healthy well-formed child, may, under this custom, lead to an aversion of the inheritance. The tenancy, in contested cases, is generally established or disproved by medical evidence: and the following are the conditions which the law requires in order that the right should exist.

1. The child must be born alive. A case has been already related, wherein the tremulous motion of a lip was held to be a sufficient proof of live birth. Some physiologists have objected to this as an inadequate proof of life (ante, p. 592), and if the question were one of physiology, and not of law, there might be some reason for the objection. In truth, however, the law does not require proof of active life in a child, but merely some evidence, however slight, that it has been born living; and the amount of proof to satisfy the purposes of justice must of course rest with those who are expounders of the law. Rare as these
cases are, one has been the subject of two recent trials (Llewellyn v. Gardiner and others, Stafford Lent Ass. 1854, and Gardiner v. Llewellyn, Stafford Summer Assizes, 1856.) This was an action of ejectment brought to try the plaintiff’s right to a life-interest in the property of his deceased wife. The plaintiff claimed as tenant by the courtesy of England, and his right depended upon whether his deceased wife had had a child born alive. According to the plaintiff’s evidence, his wife had taken a long walk, she being at the time in about the seventh month of pregnancy (November, 1851), and, having been taken ill during the night, she was suddenly delivered of a child, which lived for about a quarter of an hour. He stated that he heard the child cry. The plaintiff immediately fetched his sister, and returned with her to his wife in a few minutes, and she deposed that she heard the child cry twice. This evidence was relied upon as conclusive that the child had been born alive, although it appears on the same evidence to have died before anything could be done towards dressing it. The case for the defendants at the first trial was, that the wife was a girl of delicate health, and liable to epileptic fits: she had been married by the plaintiff, without the consent of her mother, when little more than sixteen; and evidence was given to show the improbability of the child having been born alive, there being reason to believe, from the conduct of the plaintiff and other circumstances, that it never could have had more than a fotal existence. There had been no medical examination, the body was buried the same day, and, as in the case of still-born children, neither the birth nor the burial was registered. Wightman, J. left it to the jury to say whether the positive evidence given by the plaintiff and his sister had been rebutted by the evidence given for the defendant and the other circumstances of the case. The jury found a verdict in favor of the husband’s claim. At the second trial ordered by the Court of Chancery (Stafford Summer Assizes, 1856), the plaintiff Llewellyn was made defendant; and medical and other evidence was adduced to show that the child could not have reached an age at which it could either breathe or cry. The age was variously assigned at the fourth or fifth month of gestation. The body of the child was not seen by any medical man, and the non-professional witnesses who saw it differed entirely regarding its size and appearance, so that, in fact, the case rested mainly on the credibility of the statements of Llewellyn and his sister. It appears that Mrs. Llewellyn died in 1853, having had two other miscarriages. The first trial took place in the spring of 1854, and the second in the summer of 1856, so that the disinterment of the remains, if they could have been found, would have probably thrown no light on the contested question of uterine age. In the absence of this, Mr. Berry, Professor of Midwifery, produced from the Birmingham Museum four statuses in spirits, of
from four to seven months' gestation, with a view of helping the Court to a removal of the difficulty. One witness for the plaintiff's (Gardiner), a chemist and druggist, who had seen Mrs. Llewellyn's child, fixed upon the five months' fetus as bearing the greatest resemblance to it; but the witnesses for the defendant (Llewellyn), were not recalled or asked to give any opinion on the resemblance of the fetuses. There were no medical facts to guide the jury. The late Baron Alderson, in summing up, said the question simply was whether Eliza Bennett, afterwards Eliza Llewellyn, was delivered of a living child during the time she was a wife. By what was called the "Courtesy of England," a man who married a woman, possessed of freehold property, would, if she had had a child born alive during the time they were married, be entitled to the property for his life; but if she had not had a child born alive he would not be entitled to it; that was one of the absurdities of English law! In directing the jury as to the considerations that should guide them in coming to a conclusion, his lordship said they ought to have reasonable and distinct proof of a child having been born alive when its existence was limited to a few minutes, and if a doubt was left in their mind they ought not to find in favour of the birth of the child, because the issue lay to prove that the child was born alive. If they had a doubt on the subject, and could not tell whether it was born alive or not, they must find a verdict for the plaintiffs (Gardiner); they could not find for the defendant Llewellyn unless they were satisfied that the child was in a state of life in the world during the time the husband was married to the wife. The verdict of the jury was to the effect that they did not believe the child was born alive. It was, therefore, a reversal of the former verdict.

It has been usually considered that the crying of a child, properly attested by disinterested witnesses, is sufficient evidence of live birth. This is, in fact, the test given by Lord Coke. In the section on Infanticide, some cases have been related in which new-born children survived birth several hours, but manifested no sign of active life either by crying or in any other mode, and after death there was no air in the lungs (see ante, pp. 448, 451, 465). As in cases of infanticide, if the evidence of live birth rests entirely on an examination after death, the absence of air from the lungs will not necessarily show that a child has come into the world dead, nor will the presence of air in these organs prove that it has been born alive, because it may have breathed and died before birth. The child must be heard to cry or seen to move after birth. The fact that the lungs are not distended with air, and that they immediately sink in water, either when entire or when divided into small pieces, is no proof that a child has not cried during birth and afterwards. Dr. Vernon attended a healthy woman, who was delivered of a child at about the sixth month of her

q q 3
pregnancy. The child was born before his arrival, and he heard it crying strongly from under the bed-clothes as he entered the room. After removal from the mother, the child cried at intervals, and it was observed that its chest rose and fell as in ordinary breathing. It lived five hours, and it then appeared to sink from feebleness and exhaustion. It was a female child and very small; the body weighed two pounds thirteen ounces, and its length was twelve and three quarter inches; the eyelids were adherent; the lungs were of a purplish red colour, and slightly overlapped the bag of the heart. They sank in water both entire and when divided into small pieces; they were not capillit, and broke down under firm compression:—there was no appearance of air-vessels in a section of the lungs when examined by the microscope. The ductus arteriosus and foramen ovale were in their fetal state. (Lancet, Feb. 3, 1855, p. 121.) This case has been already referred to under INFANTICIDE (p. 448, ante). Although an immature child at the sixth month, it was strong enough to cry, and yet probably, had its history been unknown, a medical witness would have been prepared to swear from an observation of the lungs that it must have been born dead, and certainly could not have had the power of uttering a cry. A child born at the fifth month has been known to cry (see post, LEGITIMACY); but the state of its lungs is not recorded. In the case of Gardiner v. Llewellyn (ante, p. 596), a medical witness who appeared for the plaintiff stated as his belief that a child born at the fifth month could not respire, and if it could not breathe, it could not cry! This may have been consistent with his experience, but it is not consistent with facts observed by others. One of the greatest difficulties that lawyers have to contend with in getting at medical truth is, in this strong disposition on the part of witnesses, to “fix” all natural events by reference to their own experience.

2. The child must be born while the mother is living. From this it appears that if a living child were removed from the outlet after the death of the mother, or extracted by the Caesarean operation from the uterus, the husband would not become entitled to enjoy his wife’s estate; although the child may survive its removal or extraction, and succeed to the estate on attaining its majority. How such a case would be decided in the present day it is difficult to determine; but one instance is quoted by most medico-legal writers from Lord Coke, in which, about three centuries since, the case was decided against the husband, in consequence of the child having been removed from the uterus by the Caesarean section after the death of the wife. (For a very singular case involving this question in France, see Ann. d’Hyg. 1838, i. 98.) In the case of Llewellyn (supra) the late Baron Alderson ruled that the husband could not take the estate unless the child were born during the marriage.
**Casarean Extraction.** — The Cæsarean operation has rarely been performed in England, except when a female was actually dying or dead. Dr. Goodman, of Manchester, has collected and published, from the table of Dr. Merriman and other sources, an account of thirty-eight of these operations performed in this country since 1737. It appears that out of this number only three mothers have recovered, the children, with one exception in the three cases, having died. In eighteen cases the children were extracted living. (Obstetric Record, No. 4, 1848, p. 3.) Dr. Goodman himself performed this operation successfully on a female in November 1845. This child was extracted alive, and the woman perfectly recovered from the operation. (Med. Gaz., xxxvi. 1392.) The practice on the Continent has been to undertake it while the woman was living, and the result has shown that it may thus be performed successfully both with regard to mother and child. (See Med. Gaz. xix. 822, 878; Cormack’s Monthly Journal, July 1845, pp. 541-543.) For a case in which this operation was successfully performed three times on the same person, see Brit. and For. Med. Rev. July 1836, 270. Important legal consequences may hereafter ensue from a more general adoption of this practice in England in respect to deformed females. Thus, supposing in any case a child were removed alive while the mother was living, both of them dying shortly afterwards,—Would the husband become a tenant by the courtesy? The law says the child must be born; and some lawyers would find ground for arguing whether extraction by the Cæsarean operation should be regarded as “legal birth.” “Illud autem validè controversum est inter jurisconsultos, an is qui editus est exsector matris ventre reputetur partus naturalis et legitimus et successionis capax.” (Caranzo.) According to Fonblanque, the question is now settled in the affirmative—a child extracted is a child born. (Med. Jur. i. 226.) Our ancient law-authorities do not appear to have contemplated that the operation would ever be undertaken on a living female. The words of Lord Coke, which are considered to express the state of the law, are:—“If a woman seized of lands in fee taketh husband, and by him is bigge with child, and in her travell dyeth, and the child is ripped out of her body alive, yet shall he not be tenant by the curtesy, because the child was not born during the marriage, nor in the life of the wife, but in the meantime her land descended.” According to Mr. Hobler, the Cæsarean operation does not divert the course of descent, or divest the husband of the life-estate, provided that the child be born alive, and the mother was living when the child was born. (Obstetric Record, iii. 66.) Birth, and extraction by the Cæsarean operation, are, therefore, treated as similar conditions.

As a proof that this operation is not always necessary, even when circumstances may appear to call for it, the following case,
mentioned by Sir B. Brodie as having occurred in a French hospital, is of some interest. It is that of a woman whose pelvis was considered to be too narrow for the egress of the child. As she was at the full term of gestation, the Cesarean section was proposed, but before the operators were ready to commence, the child was expelled by the natural efforts of the uterine, or, as a medical authority expressed it, the child preferred coming into the world by the old road! (Lancet, Dec. 1853.) This, however, is not the only case of the kind on record. There is great reason to believe that continental practitioners are too officious in suggesting the performance of this operation, and that it is often undertaken to the serious risk of the life of a female, when the case, if left to nature, would have done well. A case is reported to have occurred in Scotland in 1847, in which the Cesarean operation was considered by several practitioners of experience to be the only means by which delivery could be accomplished. Fortunately for the female, the labour was somewhat rapid, and she was delivered of a dead child, weighing about three pounds, before the arrival of those who had considered that the operation would be required. (Ed. Monthly Journ. July 1847, p. 30.) The fact is, on these occasions nature often adapts means to ends in a most unexpected manner. A case of the performance of this operation on a living female has been reported by Mr. Skey. Here sufficient time was allowed for the advancement of the labour, and it was evident to all that delivery could not take place by the outlet; that embryotomy could not be performed; and that unless the operation was resorted to, the female would infallibly sink from exhaustion. The child was extracted, but the mother died in about thirty-six hours. (Med. Gaz. xxxix. 212.)

Medical jurists have differed respecting the period of gestation at which the operation should be performed. This would of course depend on the earliest period at which a child might be born capable of living. In reference to tenancy by courtesy, a child might be extracted alive as early as the fifth month; but it would not be likely to survive unless it was at or about the seventh month. Some have alleged, that unless performed immediately after the death of the mother, the child would not be extracted living. The condition of the fetus in utero is, however, peculiar, and quite distinct from that of a child living by the act of respiration. It is possible, therefore, that there may be a limited survivorship, and that the operation may be performed so late as an hour after the death of the mother with the possibility of extracting a living child. There are incredible accounts of children having been extracted living, many hours after the death of the mother. Dr. Kergeradec states that this happened in the case of the Princess Pauline of Schwarzenburg, who, while pregnant, was burnt to death at the ball given on the occasion of the marriage of the Empress Maria Louisa
in 1810. The body was not examined until the following day, and the foetus is stated to have been then found living! (Ann. d’Hyg. 1846, i. 404.)

Birth after the death of the female.—That a child may be born after the death of the female, and survive its birth, is proved by the following case. A woman died during labour. The accoucheur, who was summoned, found the head of the child presenting, but too high up in the pelvis to allow of the application of the forceps. He immediately introduced his hand into the uterus: and a quarter of an hour after the death of the mother, and twenty hours after the rupture of the membranes, he extracted a male infant in a state of apparent death. The child, which was well-formed, was speedily resuscitated by the application of the ordinary means. (Berlin Medicin. Zeit. July 1836.) Had this case occurred in England, it would probably have been decided, according to the old precedent, that the husband could not become a tenant by courtesy, because by the death of the mother the marriage was dissolved and the land descended before the child was born! [Another case of the birth of a living child after the death of the female, will be found recorded in the Med. Gaz. vol. xlvi. p. 713.]

3. The child must be born capable of inheriting; therefore if it be a monster, the husband does not acquire the right of tenancy. There are some other legal conditions which must also be fulfilled, but I have here confined my remarks to that which may become matter for medical evidence.

Admitting that there are legal proceedings by which the obnoxious parts of this ancient custom may be set aside during the life of the wife, it is hardly just that the knowledge of the necessity for these precautions should be left to be acquired by accident. It would be better to abolish tenancy by courtesy altogether, than to allow the succession of a husband to his wife’s estate to rest upon a casualty of this kind.

Minority and majority.—The word minor is synonymous with that of infant, and is applied in law to any one under the age of twenty-one years. The age of a person may render him incompetent to the performance of civil duties. Minors are frequently called upon to act as witnesses in civil and criminal cases. In rapes committed upon young females, it is especially important to notice whether the prosecutrix be or be not competent to give evidence. The law has fixed no age for testimonial competency; and I have never heard of the question being referred to a medical practitioner. The child is always orally examined by the Court; and it is soon rendered apparent whether the witness possesses a proper knowledge of the nature and obligations of an oath. If not, his or her testimony is not received, or, in a case of rape, the trial is postponed, and the child is placed under instruction, to appear again at the following sessions or assizes. The compe-
tency of a child as a witness, therefore, does not depend on age, but upon its understanding.

According to the principles of our law, a male at 12 may take the oath of allegiance; at 14 he is considered to be at years of discretion, and becomes then responsible for his actions; at 21 he attains majority, and is at his own disposal, and may alienate his lands, goods, and chattels by deed or will. It is only when this age has been attained that an individual can be sworn to serve on a jury. The period at which a male is considered to have attained full age varies in different countries: thus, in the kingdom of Naples it is fixed at eighteen years; in Holland at twenty-five; but generally throughout the states of Europe the law prescribes twenty-one years, the same as the common law of England.

A person is completely of age the first instant of the day before the twenty-first anniversary of his birth-day, although forty-seven hours and fifty-nine minutes short of the complete number of days counting by hours; and this mode of calculating age and time is applicable to all the other ages before and after twenty-one. This is on the principle that part of a day is equal to the whole of a day in a legal point of view. The following case in reference to this question was decided by appeal in the House of Lords in February 1775. An estate was bequeathed to a Thomas Sansom so soon as he should arrive at the age of 21. He was born between the hours of 5 and 6 on the morning of the 16th August, 1725, and died about 11 in the forenoon on the 15th August, 1746. The question was, whether he had, at the time of his death, arrived at full age. In the Court of Chancery it had been so decided; but it was urged that more than sixteen hours were wanting to complete the full term. This plea was overruled by their Lordships, and the decree confirmed, because the deceased was living on the day which would have completed the period. A few minutes or hours may thus determine the attainment of majority, and with this, the responsibility of minors for civil contracts.

Plural births.—This has been regarded as a subject appertaining to medical jurisprudence; but I am not aware that there is any case on record in which the evidence of a medical man has been called for respecting it. It is a simple question of primogeniture, which has been generally settled by the aid of depositions or declarations of old relations or servants present at the birth. Women may have two, three, four, or five children at a birth. Twins are comparatively frequent, but triplets and quadruplets are very rare. A case of triplets is reported in the Lancet for October 1853, p. 316. According to Dr. Rittel, out of 574,293 births in the kingdom of Prussia in 1840, there were 6381 cases of twins, 72 of triplets, and one of quadruplets. This writer knew an instance in which a woman had six children at a birth.
(Henke, Zeitsch. 1844, 266; and Med. Gaz. xxxvi. 607.) Mr. Guthrie states, that in the museum of the Royal College of Surgeons "there is a large bottle containing five young ladies and gentlemen, all brought forth at one birth, and destroyed by an accident;" and that he was for many years acquainted with a gentleman whose mother produced twenty-eight living children in the first twelve years of her married life. (Lancet, Feb. 15, 1851, p. 176.) Mr. Russell met with a case, in 1849, in which there were five children at a birth. They were all males, and all born dead. The largest was six inches, and the smallest was five inches long. They were prematurely born. There was one placenta of the ordinary size, with five umbilical cords attached to it round its centre. (Lancet, Feb. 3, 1849.) Mr. Young states that he attended a woman who was delivered of four male children at one birth, three being from seven to eight months. They survived to the following day. One of the four was a fetus of from fifty to sixty days, apparently showing conception at different periods. There was a placenta with four navel strings quite distinct. (Lancet, March 1, 1856, p. 234.) The only circumstance with respect to these plural births which it has been recommended that an accoucheur should attend to, is the order of their occurrence. The first-born child, according to ancient principle of the common law of this country, succeeds to the inheritance. In cases of twin or triplet males, a practitioner would find himself much embarrassed to express an opinion as to which was first born after the lapse of a certain period, unless there were some personal peculiarity or deformity which would at once enable him to stamp the identity.

There is one case in which the law has interfered to prevent the inheritance of offspring, and this is in relation to monstrous births.

MONSTERS.

The connection of teratology with medical jurisprudence has been most ably investigated by M. St.-Hilaire. Although questions connected with these beings do not often occur, yet it is proper that a medical witness should be acquainted with certain facts respecting them. The law of England has given no precise definition of what is intended by a monster. According to Lord Coke, it is a being "which hath not the shape of mankind; such a being cannot be heir to or inherit land, although brought forth within marriage." A mere deformity in any part of the body, such as supernumerary fingers or toes, twisted or deformed limbs, will not constitute a monster in law, so far as the succession to property is considered, provided the being still have "human shape." Even a supernumerary leg would not probably be allowed to avert an inheritance! The trisiceps monster, in which the third leg was a fusion of two legs, was exhibited in London in 1846. (See Med. Gaz. xxxvii. 619.) From Lord Coke's description, it
is obvious that the law will be guided in its decision by the description of the monstrous birth given by a medical witness. It would not rest for a witness to say whether the being was or was not a monster—the Court would draw its inference from the description given by him. Various classifications of monsters have been made, but these are of no assistance whatever to a medical jurist, because each case must be decided by the peculiarities attending it; and his duty will not be to state the class and order of the monster, but simply in what respect it differs from a healthy organized being. In consequence of the want of a sufficient number of precedents on this subject, it is difficult to say what degree of monstrosity would be required in law in order to cut off the civil rights of a being. There are accephalous, diccephalous, and disomatous monsters; others again, like the Siamese twins, have two bodies united by a mere band of integument. Would an accephalous monster be considered as devoid of human shape? Would a disomatous monster be allowed to inherit as one?—to marry as one?—or how would legal punishment be inflicted in the event of one of the bodies infringing the laws? Such are the singular questions which have been propounded by medical jurists in relation to these beings; and there is obviously ample room for the exercise of much legal ingenuity in respect to these questions. According to St.-Hilaire, the rule which has been followed in all countries respecting these monstrosities, is to consider every monster with two equally developed heads, whether it be disomatous or not, as two beings; and every monster with a single head, under the same circumstance, as a single being. He ascribes the origin of this rule to the performance of the rite of baptism in all Christian countries upon each head, when the monster is diccephalous. This view certainly appears rational, when we consider that with two heads there are two moral individualities; while with a single head, there is only one will and one moral individuality. But it is doubtful how far this doctrine would be accepted by jurists and legislators. The question whether, in a diccephalo-disomatous monster, the two beings should be bound by the act of one, either in civil or criminal jurisprudence, is a matter which, if these monstrosities were more frequent, would give rise to serious difficulties. Such a question is not purely speculative, because it might easily have been raised in respect to the Siamese twins during their stay in this country; and according to St.-Hilaire, a case of this kind was actually decided in Paris in the seventeenth century, in relation to a double-headed monster. The author relates that this double monster killed a man by stabbing him with a knife. The being was condemned to death, but was not executed on account of the innocence of one of its component halves! (Ann. d’Hyg. 1837, i. 331.) According to the same authority, compound monstrosity is not
transmissible by generation. The reader will find an account of
the most remarkable monsters born during the present century
in a paper by Dr. Rütel (Henke, Zeitschrift der S.A. 1844, 329).
Among them is mentioned a tricephalous monster born living in
Paris in 1830. Each head was baptized under a separate name.
Monsters, especially the dicephalous, are either born dead or die
very soon after birth; yet within a recent period two have been
known to live; the one, Christina Ritta, for nine months,—the
other, the Siamese twins, who are still living.

_Christina Ritta_ was born in Sardinia in 1829. This monster
was double from the head to the pelvis; the two vertebral
columns being distinct as far as the os coccygis. The left bust was
christened by the name of Christina, the right by that of Ritta.
The monster was brought to Paris, where it died about nine
months after its birth. An excellent model of it may be seen in
the museum of Guy's Hospital, together with some good speci-
mens of the dicephalous and disomatous varieties. In the
further description of it, it may be observed, that below the
pelvis the monster is single. There are two heads resting on two
necks; and the union or fusion of the two busts is effected later-
ally towards the middle portion of the chest, so that the two
 corresponding breasts are almost blended. The abdomen, as well
as the pelvis, evidently formed by the junction of two primitive
pelvhes, is single. In the chest there were found two distinct sets
of lungs and two hearts; but these were inclosed in a single
membrane (pericardium). During life the pulsations of these
organs were so uniform that there was considered to be only
a single heart. There was only one diaphragm,—a fact which
accounted for the simultaneous death of both bodies; one only
having been previously indisposed.

_The Siamese Twins_, born in 1811, may be regarded as forming
the most remarkable duplex monster of modern times. Many
professional men must have had an opportunity of seeing them
when exhibited in London in 1830. There was such a resemblance
in their features that it was impossible to distinguish them
except by remembering their position as to the right or left hand;
They had distinct volitions, and could converse at the same time
on different subjects with different persons; their movements
were simultaneous, so as to appear like those of a single being.
In short, they could be regarded in no other light than as two
distinct beings united at the abdomens by a narrow fleshy band:
this band of union was, however, so intimate as to render it
probable that they had only one peritoneal cavity between them.
When either coughed, the band swelled up in its whole length; this
formed an insurmountable obstacle to their separation. It would,
however, have been impossible, in relation to civil and criminal
jurisprudence, to have made both responsible for the acts of one,
since they occasionally differed in opinion! Dr. Fifield, of Wex-
mouth, Massachusetts, has informed me that in July 1853 the Siamese twins were residing on a large plantation which they possessed in Chester County, North Carolina. They had then attained the mature age of 42. Some medico-legal difficulties of a civil nature had been solved by their entering into a matrimonial state. They were married to two sisters, and therefore had entered into the contract as separate beings: but no charge of bigamy had arisen out of this double union. It is probable, also, although I have no information on this point, that they enjoy the rights of citizenship as two independent beings. It is clear from this independence of will and action, that one might kill a person under circumstances which would constitute murder or manslaughter, the other not being an assenting party and endeavouring to prevent the perpetration of the crime. The application of the criminal law would, as in the Parisian case related by St.-Hilaire, become a subject of great difficulty. No punishment could be inflicted on the guilty without necessarily involving the innocent (undivided) moiety. Such a case of monstrosity is quite sui generis, and must be regarded as setting at defiance all the ordinary rules of law, whether civil, criminal, or canonical.

For an account of a case of a monocephalic disomatosus monster, which was born alive, but died soon after birth, see Ed. Med. Jour. lv. 76; and at page 435 of the same volume is an account of a dicephalous monster born at Manchester in 1840.

Malpositions, transpositions, or defects of the internal organs of any of the cavities, do not form monstrous births within the meaning of the English law. The legal question relates only to external shape, not to internal conformation. It is well known that many internally malformed persons live to a great age; and it is not until after death that malpositions and defects of this kind are discovered. In French jurisprudence the case appears to be different: if the malposition or defect were such as to become a cause of death soon after birth, the child would be pronounced not "viable," and therefore incapable of acquiring civil rights. Some medical jurists have discussed the question of "viability" in new-born children, i.e. their healthy organization with a capacity to continue to live, as if it were part of the jurisprudence of this country; but I am not aware of any facts which bear out this view. The English law does not regard internal monstrosity as forming a bar to civil rights: and the cases of Fish v. Palmer (ante, p. 592) and of Llewellyn v. Gardiner (ante, page 596) show clearly, that the simple question in English jurisprudence, is not whether a child be or be not "viable," but whether it has manifested the least sign of life after it was entirely born. The French law is much more complex, and throws a much greater degree of responsibility on French medical jurists. (See Viability, post.) It is proper to state that no person is justified in destroying a monster at birth (see ante, page 491.)
LEGITIMACY.

CHAPTER LII.

Legal presumption of legitimacy. — Every child born either in lawful matrimony, or within a period after the death of the husband in accordance with the natural duration of gestation, is considered by the English law to be the child of the husband, unless the contrary be made clearly to appear by medical or moral evidence, or by both combined. It is only in reference to medical evidence that the subject of legitimacy can here be considered; but it is extremely rare to find a case of this kind determined by medical evidence alone. There are generally circumstances which show that a child whose legitimacy is disputed, is the offspring of adultery, while the medical facts may be perfectly reconcilable with the supposition that the claimant is the child of the husband. These cases therefore have been repeatedly decided from moral evidence alone,—the medical evidence respecting the period of gestation or physical capacity in the parties leaving the matter in doubt. The law which formerly prevailed in this country was to the effect, that if a child were born during marriage,—the husband being within the four seas of the realm (intra quatuor maria), and no physical impossibility being proved, the child was legitimate. Access was presumed unless he could prove that he was "extra quatuor maria" for above nine months previously to the birth. (Blackstone, i. 456.) But the
present state of the English law on the subject appears to be this. A child born during marriage is deemed illegitimate, when by good medical or other evidence it is proved that it was impossible for the husband to be the father, — whether from his being under the age of puberty, from his labouring under physical incapacity as a result of age or natural infirmity, — or from the length of time which may have elapsed since he could have had intercourse, whether by reason of absence or death. With proof of non-access or immorality on the part of the mother, so important on these occasions, a medical witness is not in the least concerned. In a case of voluntary separation of husband and wife, which the law does not recognise, the children born are the children of the husband, unless non-access can be clearly proved. In January 1849, a woman applied to a magistrate for a summons against a man to show cause why he refused to contribute to support a child of which she declared him to be the father. It appeared that she parted voluntarily from her husband, and had lived three years with the adulterer, and during the last year the child was born. The magistrate declined granting the summons, as she had no claim upon the adulterer. There was opportunity of access on the part of the husband, and he alone was liable in law for the maintenance of the child. In some instances, the law assumes without medical evidence that the offspring is illegitimate, as where the husband and wife have been legally divorced “a vinculo matrimonii.” When children are born where the divorce is “a mensa et thoro,” they are presumed to be illegitimate until the contrary appear. There is a peculiar difference in relation to legitimacy between the laws of England and Scotland. A child born of parents in Scotland before marriage, is rendered legitimate by their subsequent marriage. In England the offspring is illegitimate, whether the parents marry or not after its birth; and under the Poor Law Act, 4 and 5 Will. IV., if a man marry a single woman having a child or children living, of whom he is not the father, he is bound to maintain them, as if they were his own and born after marriage. At the same time the children are not legitimated by the marriage. In the case of Birtwistle v. Vardell, decided on appeal by the House of Lords, in August 1840, it was held that a child thus legitimated by the law of Scotland, could not be allowed to succeed to his father as heir to real estate in England. The Scotch rule appears to be more consistent with natural justice; since, according to the English practice, it is inflicting confiscation on the offspring for a fault in the parents, which they had done all in their power to amend. (See also the case of Dalhousie v. M'Douall, on appeal to the House of Lords, March 1840.) These suits are chiefly instituted in respect to the right of succession to property or claims for peerages; and medical evidence is then frequently required to clear up the case.
From what has been stated, it will be perceived that the English law does not regard the date of conception, which cannot be fixed, but the date of birth, which can be fixed. Medical evidence may relate—1. To the actual length of the period of gestation:—this may be in a given case so short or so long, as to render it impossible that the husband could be the father. 2. There may be physical incapacity in the husband,—he may be too old or too young,—or he may labour under some physical defect rendering it impossible that he should be the father. 3. There may be sterility or incapacity in the female, rendering it impossible that the child should be the offspring of a particular woman:—in other words, the claimant may be a supposititious child. (See **Supposititious Children**, post p. 652.)

Children born after the death of the wife or husband.—It appears that a child born after the death of the mother, provided she be lawfully married, is legitimate, although the marriage is dissolved by the death. This is not a mere hypothetical question. Two cases have already been quoted (ante, p. 601) in which living children were born after the death of the females: these facts are of especial interest in relation to tenancy by courtesy. Whether the birth take place by the aid of art through the outlet, or by eventration, as in the Caesarean section, the husband, if the wife be at the time legally dead, cannot claim the estate; but the child thus born out of marriage is legitimate, and if it live, may, on attaining its majority, take the estate of which the mother was seised. (See ante, Caesarean operation, p. 599.) The fact that the English law disregards the place or date of conception might therefore give rise to a singular question. A child may have been conceived before the marriage of the parents, and be brought into the world by the Caesarean operation after the death of the mother. Hence it would neither be **begotten** nor **born** in wedlock, and yet, according to the principle of the English law, it would be the legitimate offspring of the marriage!

It frequently happens that a child is born after the death of the husband. Conception is assumed to have taken place during wedlock, and although the child is not born in wedlock, the presumption is in favour of legitimacy, unless non-access or physical incapacity be distinctly proved. The legal questions which may arise under such circumstances are elsewhere considered (see post, Posthumous Children, p. 647). Hence conception during wedlock, and birth after the dissolution of the marriage by death,—or conception before wedlock and birth during that state,—or conception and birth during lawful wedlock, equally create a presumption in favour of the legitimacy of offspring.

**Natural period of gestation. Duration from one intercourse.**—The first point to be considered is,—what is the natural period of gestation, and whether this be fixed or variable. According to
the testimony of experienced accoucheurs, the average duration of gestation in the human female is comprised between the thirty-eighth and fortieth weeks after conception. Numerous facts show that the greater number of children are naturally born between these two periods. Out of 186 cases reported by Dr. Murphy, the greater number of deliveries took place on the 285th day. (Obstetric Report, 1844.) Among five hundred cases observed by the late Dr. Reid there were 283 cases in which the period of gestation was within 280 days; and 217 cases in which it went beyond this period. Dr. Duncan found in a group of forty-six cases, that 275 days is the average interval between that which he terms insemination (intercourse) and parturition. The largest number of cases on any particular day was seven on the 274th day. (Ed. Monthly Journal, 1854, vol. ix. p. 230.) The most common cause of this variation in time is, that the usual mode of calculation by reference to the suppression of the menstrual discharge, even in a healthy female, may lead to a possible error of two, three, or even four weeks, since there is no sign whereby, in the majority of women, the actual time of conception can be determined. Some females have been able to determine by peculiar sensations the time at which they have conceived, but as a general rule this must be a matter of pure conjecture when they are living in connubial intercourse.

On the other hand, accidental and isolated cases have clearly proved that a great difference naturally exists among females with respect to the period of gestation; and it is probable that in no two is it necessarily the same. When there has been only one intercourse, the duration of pregnancy may be calculated without reference to any changes in the female constitution: for the date of conception, within certain limits to be presently mentioned, would be fixed. Observations of this kind have shown that females have differed from each other; and in several instances the time has exceeded or fallen short of the period of forty weeks, which has been usually set down as the limit of natural gestation. In three cases of this kind known to Dr. Rigby, labour came on in 260, 264, and 276 days, making a difference of sixteen days. (Med. Times, March 14, 1846, 471.) In three other instances which were privately communicated to me by Dr. S. W. J. Merriman, labour commenced at 281, 283, and 286 days respectively after one intercourse; and in a case which occurred to Dr. Reid, the labour did not commence until after the lapse of 293 days from a single intercourse. (Lancet, July 20, 1850, p. 79.) In two cases communicated to me by Mr. Carrington in November 1857, the females were delivered respectively in 249 days, and in 260 days after a single intercourse. In a third in which pregnancy was the result of a rape, there was an interval of 261 days between intercourse and delivery. Hence it will be perceived that in well-observed cases,
where there could be no motive for misstatement, and in which the characters of the females, some of whom were married and had already borne children, were beyond the reach of suspicion, a difference of not less than thirty-three days has been observed to occur,—i.e. between the earliest case recorded by Dr. Rigby, and the latest reported by Dr. Reid. This is worthy of remark, because in a case to be related hereafter (Luscombe v. Prettyjohn, post p. 637), it was held that 299 days, only six days longer than in Dr. Reid's case, was an impossible period for human gestation! In addition to the above facts, showing the variability of the period after a single intercourse, the following may be cited. Dr. Macilwain, U.S., has reported a case of gestation, which he thinks must have extended to 296 or at least to 293 days. (Amer. Jour. Med. Sci. July 1848.) In the same journal for July 1845, p. 241, there is recorded the case of a woman, a primipara, who was delivered on the 309th day after a single intercourse. Dr. Lockwood has published the following as the result of his experience. The actual duration of the term of gestation in the human subject, i.e. the interval between intercourse and delivery, was ascertained by him in four cases:—No. 1, aged 19, duration 272 days, first confinement; No. 2, aged 30, first confinement, duration 276 days; No. 3, aged 17, duration 270 days; No. 4, aged 44, seventh confinement, duration 284 days, the child weighing fourteen pounds. (Brit. Amer. Jour. Dec. 1847, 214.) M. Devilliers has also published the particulars of nine cases, in which the interval from a single intercourse was accurately determined. Delivery took place at the following periods:—229, 246, 257, 267, 301, 276-281, 278-283, 270, and 266-272 days, making an extreme difference of 49 days in the earliest and the latest periods between intercourse and delivery. (Gaz. Méd. Mars 4, 1848.)

Cause of the variations.—From analogical observations made on animals, it has been supposed that this variation in the period depended on the male: others have assigned it to peculiarities in the female constitution. It appears probable, from recent researches, that the duration of the pregnant state is dependent on the relative excitability of the uterine system at the menstrual periods. Numerous facts tend to show, that notwithstanding the general suppression of the menses, there is great excitement of the uterine system at what would have been, in the unimpregnated state, the regular menstrual periods. Sometimes, as it has been elsewhere stated, this really amounts to a periodical discharge of blood. There is also good reason to believe that abortion takes place more readily at these than at other periods. Hence some accoucheurs are inclined to consider that the duration of pregnancy is really a multiple of the menstrual period; and that in the majority of females it will occur at what would have been the tenth menstrual period, or forty weeks from the
date of intercourse and supposed conception (Gaz. Médicale, 4 Decembre, 1847, p. 968); and according to the degree of excitation of the uterine system, the child may be expelled a period earlier or a period later than that which is assigned as the usual natural term. It is in some respects a confirmation of this view, that the menstrual function is again frequently established one month after parturition. Dr. Reid, however, states that the exceptions to this are so numerous as to destroy its value as a rule. Admitting that conception may occur at any time between two menstrual periods, this theory will explain the variations which have been noticed in the duration of pregnancy after one intercourse. Dr. Rigby thinks that parturition takes place at the fortieth week, because the development of the child then acts by distending the uterus, which, in its irritable state, tends to throw it off. It is not, however, found that the duration of pregnancy is at all dependent on the size and weight of the child, or that children born at the fortieth week resemble each other in these respects. Hence the commencement of parturition cannot be ascribed to the physical conformation of the child. It would be desirable to know whether this periodicity can be invariably traced in the time at which labour commences. Some females menstruate every three weeks: so far as I can ascertain, it has not been shown that in them the correspondence of gestation to the menstrual periods has been made out. Such females should, according to the theory, bear children to the thirteenth period from the date of the last cessation. Dr. Clay believes, from the observations which he has made, that the variation in the period of gestation is dependent on the age of the female as well as of the male. He considers that the term of gestation is extended in proportion to the age of the female, and that while in a female of 17 the period may be taken at 270 days,—in a woman of 44 it would extend to 284 days. Again, when a female has been impregnated by a male much older than herself, the term of utero-gestation is, in his opinion, longer than would be assigned to a female of this age, and vice versa. (Record of Obstetric Medicine, June 1848, 212.)

It has been supposed that cases of lengthened gestation were nothing more than instances of protracted parturition; the pains indicative of delivery commencing at the usual time, but continuing over a much longer period than usual. In an instance mentioned by Dr. Jorg, a woman went her full time, but the parturition lasted a fortnight longer, the symptoms appearing and then disappearing. Admitting that this occasionally happens, still it shows that gestation from a particular pregnancy may be protracted considerably beyond the ordinary period.

There is no reason to believe that the sex of the child has any direct influence on the length of the pregnancy. It has been supposed that gestation was longer with male than female chil-
DATE OF CONCEPTION.

...and evidence of this kind was tendered in the Gardner Peerage case. A medical witness then stated, that the average period was 280 days for a female, and 290 days for a male child. The Solicitor-General very properly inquired—Supposing the child is an hermaphrodite, what then is the time? The witness said—He would take between the two! It is not observed that children labouring under sexual deformity are born earlier or later than those in which the sexual organs are perfectly developed. As an answer to this singular hypothesis it may be observed, that of Dr. Murphy's two most protracted cases (Nos. 183 and 184, post, p. 628), the one was a female, and the other a male child.

**Date of conception.**—Another and very probable cause of the differences is that the date of conception is not the same after a single intercourse in different females. It is customary for physiologists to date conception from intercourse; but the researches of Bischoff and Raciborski have shown that a variable interval may elapse according to the situation of the ovum at the time. Bischoff believes that the ovum escapes from the Graafian follicle at the time when the menstrual discharge is about to cease; and he is of opinion, that to be fecundated, it must be acted on while it is in the Fallopian tube. Hence he considers, in order that impregnation should take place, that there must have been an intercourse within eight or twelve days from the cessation of the menstrual discharge: and in answer to the objection, that there are some women who become pregnant at any period, he considers that there is great uncertainty in the time at which the ovum leaves the ovary,—at which it enters the Fallopian tube, and how long a period it may take to reach the uterus, but that, as a rule, impregnation ensues shortly after menstruation. (Med. Times and Gazette, April 8, 1854, p. 354.) Raciborski thinks that the time is more limited. Out of sixteen women who gave him such information as enabled him to determine the time of fecundation, there was only one in whom this occurred so late as ten days after the cessation of the menstrual flux; and in this one, the menses had been suddenly arrested several days before the usual time of cessation, so that the extrusion of the ovum did not probably take place until about two days prior to the act of intercourse to which it owed its fecundation. (Baly and Kirkes's Recent Advances in Physiology, 1848, 58.) These authors also state that Naegle is accustomed to reckon the duration of pregnancy at nine months and eight days from the last menstrual period, and in normal cases he has found this to be correct. Dr. Oldham met with a case in which impregnation took place twelve days after menstruation; and he states that he has known it to occur at the respective times of ten days, twelve days, and even twenty-one days after the monthly periods; and he knows of no fact to disprove the opinion that the human female is susceptible...
of impregnation at any time between her monthly periods. (Med. Gaz. xliv. p. 48.) In the same volume, at page 930, Mr. Kaye has reviewed the theory of Bischoff at some length, and to his remarks I must refer the reader. According to Dr. Duncan, a single insemination at any period of the interval between two menstrual periods may result in the fecundation of the female. (Ed. Monthly Journal, 1854, vol. ix. p. 233.)

The experience of Dr. Oldham is confirmed by that of the late Dr. Reid. This gentleman admits that impregnation is more likely to occur immediately after the termination of a menstrual period, than at any other time during the interval. The next most likely period is immediately previous to the occurrence of menstruation, and the probability of conception becomes slighter as the time is more distant from this epoch. According to Rachovsky, from observations made in Paris of one hundred women, no more than six or seven had become impregnated at the mid-term from the menstrual periods. In the opinion of Dr. Reid, if we are to be guided by the number of days which have elapsed between the last appearance of the menses and parturition (this, however, he shows to be a most fallacious guide), there is no period in the menstrual interval at which impregnation may not occur (Lancet, Sept. 3, 1853, p. 206.) In cases of single intercourse, the date being certain, conception took place twelve and fourteen days after menstruation: several of these cases occurred within Dr. Reid’s knowledge. It is here assumed, however, that conception is synchronous with intercourse. It may be therefore fairly taken as a fact, irrespective of any modern theories of ovulation, that a woman may conceive from intercourse had, at the intermenstrual period (mid-period), although, in a given number of instances, it is probable that the conceptions would be more numerous within six or seven days after the cessation of the menses, than at any other period.

Recent physiological researches have proved that the date of conception is not fixed by the date of intercourse. The time occupied by the descent of the ovum along the Fallopian tube varies, while the time required for the passage of the male fluid to meet the ovum is also subject to variation. The investigations of Bischoff and Valentin show that the zoosperms may retain their movements, and probably their fecundating power for so long a period as seven days within the body of a female. Fecundation cannot result unless the matured ovum meets the zoosperms in a living condition, and conception may be regarded, in the language of Dr. Meigs, as the fixation of a fecundated ovum upon the living surface of the mother. These facts will account for some of the variations which are observed in the duration of pregnancy from a single intercourse. Conception may take place either in a few hours, or, according to Valentin’s observations, for so long a period as seven days after intercourse.
PREMATURE BIRTHS. SHORT PERIODS OF GESTATION. 615

But they do not satisfactorily explain such extreme differences as were observed in the cases of Dr. Rigby and Dr. Reid (33 days), or in those of M. Devilliers (49 days), ante p. 611. We must therefore be prepared to admit, either that conception in some cases may be delayed for so long a period as from five to seven weeks after intercourse, or that there may be this great difference in the duration of pregnancy. Whatever may be the explanation adopted, it is obvious that, in a medico-legal view, the only conclusion at which we can arrive is, that the period of gestation in the human female is not, as it was formerly supposed to be, a fixed and invariable term.

Premature births. Short periods of gestation.—From the preceding remarks we may regard all births before the thirty-eighth week as premature, and all those which occur after the fortieth week as protracted cases; and one great point for a medical witness to determine is, whether the characters presented by a child correspond to those which it should present, supposing it to be legitimately born. When the birth is premature, this sort of corroborative evidence may be sometimes obtained; because, assuming that there has been no access between the parties before marriage, children born at the fifth, sixth, or even seventh month after marriage, cannot, if the offspring of the husband, present the characters of those born at the full period. It is not so with protracted births; for children are not more developed in protracted cases, than they are in those which occur at the usual period. (For an account of the characters presented by children at different uterine ages, see ante, p. 425.)

In judging from the marks of development on the body of a child, we must make full allowance for the exceptions to which they are liable. The nearer the supposed premature delivery approaches, to the full period of gestation the more difficult will be the formation of an opinion. Although the characters of a seven months' child are usually well marked, and may be known by common observation, it is not easy to distinguish a child born at the eighth from one born at the ninth month. Burns observes that it is possible for gestation to be completed, and the child perfected to its natural size, a week or two sooner than the end of the ninth month; and other accoucheurs corroborate this view. In a series of cases which occurred to M. Devilliers, the following were the weights of children born at the respective periods:

| 229 days | 4'60 pounds av. | 270 days | 6'8 pounds av. |
| 246 " | 4'88 " | 272 " | 7'3 " |
| 257 " | 6'68 " | 283 " | 6'0 " |
| 267 " | 7'71 " |

Hence the weight of a child born in the fortieth week may be less than that of another born in the thirty-seventh week of gestation.
The weight in the third case may be taken as the average weight of a mature child, and the delivery took place three weeks before the usual period. (See Gazette Médicale, 4 Mars, 1848, p. 168.) Thus, then, a child, born at the eighth month may be the offspring of the husband:—at the ninth, of an adulterer; but medical facts could not enable a witness to draw any distinction. It is here that moral proofs are necessary; for without these the legitimacy of a child, in such a case, could not be successfully disputed. With respect to twin children the greatest differences are sometimes observed. In a case which occurred to Mr. West the first child born weighed only a pound and half; the second weighed more than three pounds, and both lived several hours. Their uterine age must have been the same. In another premature twin case which occurred to the same gentleman, one child weighed two pounds and a quarter, and the other two pounds and three quarters. (Med. Times, Feb. 23, 1850, p. 147.)

The survivorship of a child has been supposed to furnish additional evidence; for, it is well known, that under a certain age children are not born living, or if living, they speedily die. Therefore it has been argued, if a child born at the fifth or sixth month after the first cohabitation, be born living or survive, this should be taken as a proof of its illegitimacy. The following remarks will, however, show that an argument of this kind may be overstrained.

Viability. Earliest period at which a child may be born living.—According to the English law, it is not necessary that a child, when born, should be capable of living, or viable, in order that it should take its civil rights. Thus it may be born at a very early period of gestation:—it may be immature, and not likely to survive: or again it may be born at the full period of pregnancy, but it may be obviously labouring under some defective organization, or some mortal disease, which must necessarily cause its death within a very short period after its birth. Fortunately, these points are of no importance in relation to the right of inheritance: an English medical jurist has only to prove that there were signs of life after birth,—whether the child were mature or immature, diseased or healthy, is a matter which does not at all enter into the investigation. In this respect, our law appears to be more simple and just than that which prevails in France. By Art. 725 of the Code Napoléon, no child which is born alive can inherit, unless it be born, as the law terms it, viable. The meaning of this word is not defined by the law itself, and there are probably no two lawyers, or physicians, of that country, who place upon it the same interpretation. The French law seems to intend (Devergie, i. 700; Briand, 173), by viability in a new-born child, that it should be capable of living out of the womb of its mother, and independently of her:—also that it should be capable of living for a longer or shorter period after its birth. It would have been difficult for any system of juris-
prudence to have laid down a more vague or incorrect principle than this; and medical witnesses may consider themselves fortunate, that in this country they have not to take part in the litigation to which such a principle must necessarily give rise. The effect of the French law is this:—a child may be born alive; it may breathe and cry, and survive its birth for some considerable time; yet upon arbitrary medical principles, founded upon the period of gestation at which the child is born, on its length, its weight, the colour of its skin, the length of its hair, and form of its nails, it may be pronounced not viable; i.e. not capable of inheriting and transmitting property! But then, again, the child may be externally pronounced viable, and live four or five days; yet, on inspecting the body after death, if disease of the lungs, brain, or any organ, which had its origin previous to birth, be found, it will be pronounced the contrary, and the rights of property are thus made to rest upon the most trivial and unsettled conditions. The presumption is, however, in favour of the legal rights of the offspring, when it has been clearly proved that it has lived after it was born. The viability of the child is presumed, and those who would then benefit by the allegation of non-maturity, must prove it. (Briand, Man. Complet de Méd. Lég. 1846, 173.)

It may at first sight appear not quite consistent with justice, that a child which is born immature, or labouring under disease, owing to which it cannot long survive its birth, should possess the same rights of inheritance as one which is born mature and perfectly healthy; but this evil to society, if it be admitted as such, is of far less magnitude than the adoption of a system which must constantly lead to subtle casuistical distinctions, and thereby create error and confusion. So long as there is no well-defined line, between a child which is considered capable of living, and one which is not, gross injustice must necessarily be inflicted by any rule of law similar to that which is admitted in the Code of France. In a recent case an attempt was made to push the doctrine of non-viability to such a degree as actually to include cases of injury inflicted by instruments during delivery; so that by the awkwardness of an accoucheur in the use of the forceps, a well-formed healthy child might, by reason of its death soon after birth, be pronounced non-viable. M. Tardieu was consulted in a case of this kind, and by his medico-legal experience was enabled to satisfy the parties concerned, that the child was perfectly viable in a medical sense, and that its death had arisen not from any congenital disease or malformation, but from injuries inflicted by the instruments which were necessary to aid delivery. (Ann. d’Hyg. 1853, ii. 193.)

The question to be considered is,—What is the earliest period at which a child can be born, to enable it to live and to continue in life after its birth? It is now universally admitted, that
children born at the seventh month of gestation are capable of living, although they are more delicate, and in general require greater care and attention to preserve them, than children born at the ninth month;—the chances are, however, very much against their surviving. It was the opinion of Dr. William Hunter, and it is one in which most obstetric authorities consent, that few children born before the seventh month are capable of arriving at maturity. They may be born alive at any period between the sixth and seventh months, or even, in some instances, earlier than the sixth; but this is rare, and if born living, they commonly die soon after birth. There is one case on record of a child having been born living so early as the fourth month of gestation (Brit. and For. Med. Rev. ii. 236); and another of recent occurrence, in which a female aborted at the fourth month and a half of pregnancy. M. Maisonneuve was not called to this case for two hours; he then found the fetus in its membranes, and on laying these open, to his surprise it was still moving. He applied warmth, and partially succeeded in restoring it; for in a few minutes the respiratory motions were performed with regularity, but the child died in about six hours. (Journal de Médecine, and Med. Gaz. xxxix. 97.) In two instances of abortion about the fifth month, Dr. Davies, of Hertford, noticed that the fetus showed signs of life after its birth, by moving its limbs (Med. Gaz. xl. 1022); and the following case, in which a child born at the fifth month, survived upwards of twelve hours, is reported by Mr. Smythe. A female in her second pregnancy, and in the 147th day of gestation, had severe flooding with rupture of the membranes. Labour occurred on the following night, when a small but well-formed fetus was expelled, giving no other indication of life than a feeble action of the heart, and a strong pulsation in the umbilical cord. It was resuscitated, and cried as strongly as a child born at the full period of pregnancy. It weighed less than two pounds, and measured exactly twelve inches. It swallowed some nourishment, but died about twelve hours after birth. The membranes pupillares were entire,—the testicles had not descended,—the head was well covered with hair. The length and weight, as well as the presence of hair, indicated a fetus between the six and seventh months; but, as it is alleged by the reporter, that from peculiar circumstances the mother of the infant was correct in the dates, we are compelled to infer that this was an extraordinary case of premature development. There was clearly nothing in the organization of this child to have prevented its growing to the age of maturity; in other words it was viable. (Med.-Chir. Rev. July 1844, 266.) Another case is reported, in which a child born at five months and a half survived its birth between three and four hours (Med. Gaz. xix. 865); and on a trial for child-murder (Reg. v. West, Nottingham Lent Assizes, 1848), a midwife was indicted for causing the death of a child, by bringing about the
Survivorship of premature children. 619

Premature delivery of the mother when she was between the fifth and sixth month of pregnancy. The child in this instance lived five hours after its birth. Capuron mentions an instance where a child was born at the sixth month and a half of pregnancy, and at the time he reported the case, the child was two years old and enjoyed excellent health. In another instance, a child was born at the same period, and lived to the age of ten years. (Med. Lég. des Acc. pp. 162, 208.) In a case which fell under my own knowledge, a child was born at the sixth month and a half of gestation, and lived a fortnight. (See another case, Med. Gaz. xxxii. p. 623.) Capuron considers that a child born at the 180th day, or at the sixth month after conception, might be sufficiently mature to live; i.e. that there would be no reason to presume that it was illegitimate, merely because it survived its premature birth. On the other hand, if born before the sixth month with sufficient maturity to live, this fact, although by no means a proof, affords, in his opinion, a strong presumption of its illegitimacy. Of eight cases of children born living (by abortion) at the sixth month, Mr. Whitehead states that seven perished within six hours after birth, and one only attained to the age of ten days. (On Abortion, 249.) Dr. Rüttel, who has examined this subject with great care, states, as the result of his experience, that he attended a married woman, who was afterwards delivered of a living child in the fifth month of her pregnancy. The child survived its birth for twenty-four hours. He delivered another woman in the sixth month of her pregnancy, of twins,—one was dead, and the other continued alive for three hours, its life being indicated only by the visible pulsation of the heart: there was no perceptible respiration. This fact corroborates the remarks made elsewhere, as to life without active respiration, in cases of infanticide (ante, p. 448); it has also an immediate bearing on the proof of life in reference to tenancy by courtesy (ante, p. 595). In another instance of the birth of male twins at the sixth month, each weighed three pounds. Dr. Rüttel saw them a year after their birth, and they were then two healthy strong children. (Henke, Zeitschrift der S. A. 1844, 241.) Dr. Barker, of Dumfries, met with a case, in which a child was born at the 158th day of gestation, or twenty-two weeks and four days after intercourse. The size and weight of the child corresponded with the period at which it was born. It weighed one pound, and measured eleven inches. It had only rudimentary nails, and almost no hair, except a little of slightly reddish colour on the back of the head. The eyelids were closed, and did not open until the second day. The nails were hardly visible; the skin was shrivelled. The child did not suck properly till after the lapse of a month, and she did not walk until she was nineteen months old. When born it was wrapped up in a box, and placed before the fire. Three years and a half afterwards this
child was in a thriving state and very healthy, but of small make. She weighed twenty-nine pounds and a half. (Med. Times, Sept. 7, 1850, p. 249; also Oct. 12, p. 302.) Mr. Ausman, surgeon, of Kinross, has recorded a case in which a child was born between the end of the sixth and the middle of the seventh month, and lived for a period of four months and eight days. It weighed a pound and a half when seven days old. (Med. Times, Sept. 9, 1848, p. 304.) In a case which occurred to Dr. Outrepoint, of Bamberg (reported in Henke's Zeitschrift, vol. vi.), there was the strongest reason to believe that gestation could not have exceeded twenty-seven weeks. The child weighed, when born, one pound and a half, and measured thirteen and a half inches. The skin was covered with down, and much wrinkled,—the extremities were small,—the nails appeared like white folds of skin, and the testicles had not descended. It breathed as soon as it was born, and by great care its life was preserved. It is singular that its development was very slow until it had reached a period which would have corresponded to the forty-second week of gestation. Dr. Outrepoint saw the child when it had attained the age of eleven years, and then it appeared to be of the size of a boy of eight years. The only remarkable point about this case is the length of time which the child lived. In a case quoted in the Lancet, Aug. 23, 1851, p. 177, a child born at six months and ten days was thriving satisfactorily when four months old. (See also Med. Times, Feb. 16, 1850, p. 129.) A gentleman of a well-known family in Scotland was undoubtedly born before the seventh month. When first born, the child weighed three pounds. As a child he was not expected to live, but he grew up a small strong man, capable of great mental and bodily exertion: he died from natural causes at about the age of 42. His head throughout life was large in proportion to his size. It is therefore clear, that children born at the seventh, and even at or about the sixth month, may be reared, and that the fact of their surviving for months or years cannot be taken as evidence of illegitimacy. In forming a judgment on these occasions, we are bound to look less at the period at which the child is born than at the marks of development about its body. The case of Mr. Smythe (supra) is corroborative of this view. Such, I believe, are the principal medical facts connected with the question of premature births; and the following singular case will serve as an illustration of the difficulties sometimes experienced in forming a medical opinion.

The Kinghorn case.—In October 1835, an investigation (fama clamosa) took place before one of the Presbyteries of Scotland, in reference to certain reports which had been circulated, to the prejudice of a minister of the district. It appears that the marriage of this gentleman took place on the 3d of March, and his lady gave birth to a female child on the 24th of August following; i.e., one hundred and seventy-four days, or nearly
six calendar months, after the marriage, and the child continued
to live until the 20th of March, 1836. When born it was very
weak, and, according to the evidence of the accoucheur and others
who saw it, it was decidedly immature. The birth of a living
child, together with the fact of its surviving for so long a period,
led, however, to the report that there must have been intercourse
between the parties previously to the marriage. It was contended
that the period was too short for the child to have been begotten
in wedlock. Dr. Hamilton, of Edinburgh, on being applied to
by the Presbytery, said that his own experience was opposed to
the probability of a child born at the sixth lunar month surviving
(the time in this case was six lunar months and six days); but
he referred to two cases, where children born under similar cir-
cumstances had survived their birth for a long period. In one,
the lady was delivered within five lunar months (twenty weeks)
after the marriage, and Dr. Pitearn and others gave it as their
opinion, that it had been begotten within wedlock; in the
other, a woman gave birth to a child nineteen weeks after con-
ception, and it lived a year and a half. Dr. Thatcher, who ex-
amined the child in the case here reported, nineteen days after
its birth, gave it as his opinion that it might have been begotten
on or after the 3d of March; and the circumstance of its having
been reared in the premature state in which it was born on the
24th of August following, was no objection to this opinion. He
considered the complaint made against the minister, groundless.
The case went through several appeals, and was not finally decided
until May 1839, when the libel was found not proven, and the
defendant was absolved from censure. Many medical witnesses
gave evidence on the occasion: — the majority of them were
strongly in favour of this having been a legitimate and premature
birth. (See Record of Proceedings, &c. Edinburgh, 1839; Med.
Gas. xvii. 92; also Med.-Chir. Rev. xxxi. 424.) Although not
connected with the medical part of the case, it should be observed,
that the character of the parties was free from all suspicion, that
no concealment had been practised by them, and that no prepara-
thad been made for the early birth of the child. There were,
it is true, unusual marks of development about the child, consider-
ing the early period of its birth; yet these were not sufficient,
any more than the fact of its surviving, to induce the belief that
it had been begotten out of wedlock. One case has been already
mentioned, in which a child born at a still earlier period, survived
several hours, and others in which children born rather later, lived
for two and ten years. It would be in the highest degree unjust
to impute illegitimacy to offspring, or a want of chastity to
parents, merely from the fact of a six months' child being born
living and surviving its birth. There are, indeed, no justifiable
medical grounds for adopting such an opinion,—a fact clearly
brought out by a question put to Dr. Campbell, the chief medical
witness in favour of the alleged antenuptial conception. In his
examination in chief, he admitted that he had himself seen the
case of a six months’ child who survived for several days. He
was then required to say, whether he could assign any reason why,
if after such a period of gestation it is possible to prolong life
for days, it should not be possible to extend it to months? He
could obviously give no reason. (Record of Proceedings, &c. 55.)
The great injury which may be done by speculative medical
opinions, such as those given against the chastity of the parties
concerned in these proceedings, will be apparent from the record
of a case which occurred to Dr. Halpin, of Cavan, in 1845:—A
healthy woman, aged 34, the mother of five children, was delivered
in the sixth month of her pregnancy of a female child. It was
rolled in flannel, and laid in a warm place. Contrary to expecta-
tion, the child survived, sucked vigorously, and was healthy in
every respect. The ossification of the bones of the head was
very imperfect, and the sutures broad enough to admit of the
middle finger being laid between them; and the fontanelles were
of correspondingly large size. The weight of the child, on the
fourth day after birth, was two pounds thirteen ounces; and on
the thirty-fourth day, three pounds seven ounces. The child was
alive and well when last seen on the 4th of March,—i. e. four
months after birth: she then weighed eight pounds eight ounces.
After this, Dr. Halpin lost sight of her, as the mother left that
part of the country. (Dublin Quarterly Journal, May 1846, p.
563. See also Dr. Barker’s case, ante, p. 619.)—If the facts of
these cases be compared with those of the Kinghorn case, it will
be seen that there were no just medical grounds for the allega-
tion that the child had been begotten out of wedlock. In these
two cases six months’ children were living and healthy after
four months and three years and a half, respectively: in the
Kinghorn case, it was supposed that the child must have passed
the sixth month (of uterine life), because it had survived seven
months! In Dr. Halpin’s case, the child, four days after birth,
weighed two pounds thirteen ounces,—(a six months’ child
rarely exceeding two pounds): in the Scotch case, it was con-
sidered that it must have been much beyond the sixth month,
because (a fortnight after its birth) it weighed three pounds!
These cases should be borne in mind, when much reliance is
placed upon the appearances presented by children as positive
evidence of the stage of uterine life which they are supposed to
have attained.

Evidence from the state of development of the offspring.—The
fact that a child born at nine months is small, and resembles in
size and weight a seven or eight months’ child, cannot be taken
as a proof of illegitimacy. It has been already stated, that
children born at the full period vary considerably in size and
weight; yet, although small, there are commonly about them the
appearances of development. This is especially apparent in the features. If there be a general want of development in the body, and if certain fetal peculiarities remain,—as for example, the membrane papillares, or, in the male, the testes do not occupy the scrotum, these facts may lead to a strong presumption that the child has not reached the full period. On the other hand, when a child is born with all the signs of maturity about it, at or under seven months (from possible access of the husband), then there is the strongest reason to believe that it is illegitimate. No instance is recorded in which children have reached maturity two months earlier than the natural period. There are many cases of retarded development; but, so far as I know, this kind of premature development in the fetus has never been observed. In the Scotch case above related, the child was more developed than such children commonly are at the same period of uterine life; but these differences are slight. The great progressive stage of development is in the two last months of gestation: the changes which the fetus undergoes are greater, and more marked, at this than at any other period. At eight months there might be some difficulty in forming an opinion; but it appears to me, that at seven months it would be impossible for an accoucheur to commit an error on this point. If the body of a child were large and fully developed, he would consider it to have been born at the full period of gestation, and attribute any opinion which had led to the supposition that it was a seven months' child to have arisen from some mistake in the calculation. Dr. Beck states it as barely possible that a child born at seven months may occasionally be of such a size as to be considered mature, yet he qualifies this statement by the remark, that the assertion is most frequently made by those whose character is in danger of being destroyed. The question is, however,—Has a really seven months' child ever been born so developed as to be mistaken by an experienced person for one that was mature? He adduces no case of this kind in support of his opinion. There can be no doubt of the correctness of his statement, that a mature child, born before seven full months after intercourse, ought to be considered illegitimate: but it would be difficult to maintain this position, consistently with the above admission; for a child is as likely to acquire premature development during the latter half of the sixth as at the seventh month. In making this remark, I ought to mention that Dr. Rüttel, an experienced observer, has met with several cases in which females have been delivered two and even three weeks before the expiration of the ordinary term (two hundred and eighty days), and the children were perfectly developed, to all appearance, as those born at the full period. (Henke, Zeitschrift, 1844, p. 246.)

The following case in reference to development has been communicated to me by one of my pupils. It is well calculated to
show the characters of a seven months’ child, and to corroborate
the views adopted by physiologists respecting the means of
determining the period of uterine life which the facts may have
reached. Mrs. F. was married on the 7th April, 1845, and was
delivered by my informant of a male child at seven o’clock on the
evening of the 19th October following,—the period of gestation
being equal to 195 days, or twenty-eight weeks. The infant cried
strongly, and lived until nine o’clock the following morning. The
skin was of a deep pink or rose colour, beautifully soft, and
covered with a fine down. The membrane pupillares were absent,
and the pupils were well formed,—the nails were complete,—the
testicles had not descended into the scrotum,—its length was
fifteen inches, and its weight two pounds eight ounces. In
weight, and the non-descent of the testicles, at once referred
it to a uterine age of seven months.

In addition to the other circumstances mentioned, it is ob-
served that children at the seventh month do not so readily take
the breast as those which have reached the ninth; and their
power of sucking is much more feeble.

When the facts are such, that to be the offspring of the
husband it must be a six months’ child, and it is born mature,
there can be no room to doubt its illegitimacy. This question
was raised in the Exchequer Sittings (January 1847), on a
motion for a new trial in the case of Eager v. Grimwood. The
action was one for seduction, and the principal witness in the
case, a young female, on being cross-examined, stated that she was
first connected with the defendant a few days before Christmas
1845, and that the birth of the child took place in the June
following,—i. e. in about six calendar months. Under these cir-
cumstances, as the child appeared to have been full-grown, the
Chief Baron, assuming the statement of the dates to be correct,
implied it to be his opinion, that the action could not be
maintained, as the foundation of it was the loss of service, arising
from the defendant’s intercourse with the daughter, and her sub-
sequent confinement; and that it was impossible that he could
have been the father of the child in question. The jury found
for the defendant. A rule for a new trial was granted, chiefly
on the ground that the woman had, from confusion in giving her
testimony, made a mistake in the period. This question may
arise in cases of divorce, and the fact be received as proof of the
act of adultery. In the case of Maclean (House of Lords,
March 1851), it was proved that the earliest intercourse which
could have been had with the husband was on the 22nd December,
1847; while according to the medical evidence the child was
born on the 6th July, 1848, and was a full-grown ninth months’
child. This was received as proof of adultery on the part of the
wife. In Heathcote’s case (March 1851); it was proved that the
husband returned on the 24th November, 1849, and the wife
was delivered of a full-grown child on the 18th May 1850. This was also taken as proof of the alleged adultery. In Hawkins's case, May 1852, it was proved that there had been no access of the husband, owing to his absence between the 16th May 1850, and the 23rd March 1851. A full-grown and mature child was born on the 2nd June 1851: hence, to have been the child of the husband, gestation must have been extended to a year and sixteen days, or reduced to a period of only seventy-one days. This was taken as clear proof of adultery on the part of the wife. It is to be remarked of this case that the husband had slept with his wife after his return, even up to five minutes of the time of her delivery, without suspecting his wife's pregnancy; and her female attendant, who had been in the habit of seeing her daily, did not observe any alteration in her personal appearance. This created a little difficulty in the case: but it merely serves to show that a visible prominence of the abdomen is by no means a constant accompaniment of the pregnant state, or that it may be very readily concealed.

Protracted births. Long periods of gestation.—The questions connected with retarded gestation have given rise to considerable discussion in legal medicine. That gestation may be retarded or protracted beyond the fortieth week, is now, I believe, not disputed by any obstetric writer of reputation. Some accoucheurs have denied it, because they have not met with such cases; but the medicolegal relations of such questions do not depend upon the solitary experience of practitioners. It is only by the accumulation of well-ascertained facts from all authentic sources that medical knowledge can be made available to the purposes of the law: otherwise, owing to the mere accident of a witness not having met with any exceptional case, a Court may be entirely misled in its judgment by trusting to his opinion. It is the more important to attend to this, because most of the cases involving questions of contested legitimacy, or the chastity of females, turn upon protracted, rather than upon premature delivery.

In the standard works on midwifery will be found authentic reports of cases in which gestation continued to the forty-first, forty-second, forty-third, and even the forty-fourth week. Dr. Murphy regards 301 days, or 43 weeks, as the average limit of gestation. (Obstetric Report, p. 4.) Dr. Lee met with a case in which he had no doubt that the pregnancy lasted two hundred and eighty-seven days: — the labour did not take place until forty-one weeks after the departure of the husband of the lady for the East Indies. (Med. Gaz. xxxi. 917.) Dr. William Hunter met with two instances in which gestation was protracted until the forty-second week. Dr. Montgomery met with a case in which delivery did not ensue until between the forty-second and forty-fourth week. (Med. Gaz. xix. 646.) Dr. Merriman has published a valuable table on the subject of protracted gestation, on
which the most experienced accoucheurs have been in the habit of relying. Of one hundred and fourteen pregnancies calculated by him from the last day at which the females menstruated, and in which the children appeared to be mature, the following were the periods:

<table>

Another well-marked case occurring forty-four weeks precisely after the cessation of the menses, has been communicated to me by Dr. S. W. J. Merriman.

From these results Dr. Merriman considers that the greater number of women complete gestation in the fortieth week from the cessation of the menses, and next to that in the forty-first. In the evidence given by this gentleman before the House of Lords in 1825, the case of longest protraction on which he was able to rely, was that of a married female, who was in the habit of calculating from the last day on which her monthly period ceased. This lady was delivered 309 days, or forty-four weeks and one day, from the time at which she supposed that she had conceived. In another case mentioned by the witness the period was 303 days, or forty-three weeks and two days from the termination of the last monthly period. It was objected to this evidence by the Attorney-General that it was impossible to fix the exact date of conception, and as the female might have really conceived only a day or two before the expected return of menstruation,—twenty-eight days, or four weeks, should be deducted from the periods assigned by the witness. Admitting the validity of this objection,—and the fact upon which it is based is indisputable,—it followed that the longest protracted case observed by Dr. Merriman might have really been only a case of ordinary gestation, extending to forty weeks and one day. An objection of this kind may of course be successfully urged in law to any inference from a calculation so made, and it was thus that in the Gardner Peerage case, the medical evidence failed to render it certain that gestation might be so protracted as to support the legitimacy of the claimant. It is therefore obviously of the greatest importance, in considering this question, to make full allowance for a possible error; and in calculating the pregnancy from the last day of the last menstrual period, to deduct the interval of menstruation, if known, and at least twenty-eight days if unknown. It must be remembered, that in these cases of contested legitimacy the offspring is commonly the result of a single intercourse. The date of conception is therefore fixed within limits already described (ante, p. 618), and a comparison can be instituted only between the period of gestation thence deduced, and the
periods taken in other cases which are equally free from any
error.

A well-marked case of gestation passing beyond what is com-
monly set down as the average period, has been communicated
to me by Mr. Howell, of Walton-on-Naze. This occurred in a
healthy female, aged 30, who had borne three children, the youngest
being four years old. She had menstruated with regularity up to
the third week in June: the menses then stopped without
any apparent cause. Her delivery took place 323 days after the
last appearance of the menses. Allowing that impregnation
occurred at the inter-menstrual period, this would make the
gestation 309 days; or assuming that impregnation did not occur
until twenty-eight days from the date of the last menstruation,
this would make the period 295 days, or forty-two weeks and one
day. Dr. Murphy, of University College, has also furnished me
with some facts in reference to this subject. Out of 182 cases in
which special inquiries were made of the females, the deliveries
took place from the date of the last appearance of the menses at
the following periods in weeks. The details are given in his
Report of the Obstetric Practice of University College Hospital
for 1844.

In the 33rd week . . . . 5 In the 40th week . . . . . . 25
34th . . . . 3 41st . . . . . . 32
36th . . . . 6 42nd . . . . . . 25
37th . . . . 11 43rd . . . . . . 19
38th . . . . 12 44th . . . . . . 9
39th (9 months) . . . . 24 45th . . . . . . 11

The most protracted of the cases in the table was No. 182.
The period of gestation was 329 days, or deducting twenty-eight
days (the ascertained menstrual interval), 301 days, or forty-three
weeks; i.e., three weeks beyond the usual period, or that allowed
by the medical witnesses who gave evidence against the possible
protraction of pregnancy in the Gardner Peerage case.

It will now be proper to direct attention to some still more
protracted cases which are recorded by writers of repute, and
which have either fallen under their own observation, or under
that of friends upon whose judgment they could rely. Among
these a case is reported by Dr. Beck to have occurred in America
in 1840, in which gestation is stated to have extended to 313
days, or forty-four weeks and five days; but, as the facts are not
fully detailed, I prefer taking for illustration two cases observed
by Dr. Murphy, and recorded in his Obstetric Report for
1844. He states that No. 183, a healthy married woman, aged
26, pregnant with her third child, was delivered 342 days from
the last appearance of the menses. The date at which they were
last observed by her was the 1st September, and the woman was
delivered on the 9th August of the following year. In No. 184,
a married woman, aged 33, pregnant with her fifth child, delivery took place at an interval of 352 days. The menses last appeared on the 1st of March, and the child was born on the 16th of the following February. In both instances the menstrual interval was observed to be four weeks; therefore, deducting twenty-eight days, the periods of gestation in these two cases will be—

<table>
<thead>
<tr>
<th>No.</th>
<th>(342—28)</th>
<th>314 days</th>
<th>44 weeks and 6 days</th>
</tr>
</thead>
<tbody>
<tr>
<td>No. 183</td>
<td>(352—28)</td>
<td>324</td>
<td>46 &quot; 2 &quot;</td>
</tr>
</tbody>
</table>

As these cases are of an unusual kind, the facts are specially detailed. Dr. Murphy observes, in respect to the longest case "that the date of the last menstrual discharge in this, as in other cases, was recorded before parturition took place; thus preventing the possibility of mistaking this fact for the purpose of making it appear that gestation was inordinately prolonged. Menstruation, however, is sometimes suspended, or may return at irregular intervals during pregnancy; it was possible, therefore, that the menses might have appeared in this irregular way, occurring but once, and that time being put two months before conception. It was necessary to avoid this source of error. This irregularity did not take place in either of the cases, and in the last instance there was an interval of four years between the present and the previous pregnancy, during the whole of which period to the time of conception the menses were quite regular." (Report, page 7.) Dr. Murphy has since published a case which occurred in his practice in 1849: the duration of pregnancy was 351 days, or deducting the monthly period (351—28) 323 days. (See Med. Gaz. 1851, vol. xlvi. p. 683.) I am indebted to Dr. S. W. Merriman for a reference to another case, which goes one day beyond the longest of Dr. Murphy’s, i.e., 325 days, or forty-six weeks and three days. This is reported by Dr. Power, in his work on Human Pregnancy. Mr. Chattaway, of Knighton, a former pupil, has communicated to me a remarkable case of protracted gestation, which tends to support the observations of Dr. Murphy and others. A healthy woman, 36, the wife of a farmer, applied to him to attend her in her confinement, which she expected to take place in September, 1856. The menses appeared for the last time in December, 1855, and she quickened in the beginning of April, 1856. About the middle of September (i.e. on the 283rd day, dating from the last menstruation), Mr. Chattaway was summoned to attend her, and he found her labouring under severe false pains. There was also a discharge of mucus tinged with blood. The case went on until Nov. 19th, 1856, when the patient was delivered of a female child of the average size. It would thus appear, according to the ordinary mode of calculation, that deducting twenty-eight days from the last appearance of the menses, gestation was pro-
TRACTED IN THIS INSTANCE TO 330 DAYS, OR FORTY-SEVEN WEEKS AND ONE DAY.

These cases, assuming the facts to have been correctly observed and reported, meet the objection taken to Dr. Merriman's evidence in the Gardner Peerage case. All women may not have such unusually protracted pregnancies; indeed, it is well ascertained that no two women are alike in this respect, and that two successive pregnancies in the same female are rarely alike in duration. Then, again, all practitioners may not have met with such protracted cases. The fact being clearly ascertained in one case, renders it unnecessary to search for more, unless we doubt the credibility of a reporter well qualified to observe, and who could have had no motive to serve but that of stating a plain truth as it came before him. On this part of the question I think it is unnecessary to argue. The advocates of a fixed and limitable period differ from each other by a space of ten or twelve days, and each must either take his own experience for the final decision of this question, or it must be allowed that men of equal powers of observation with themselves, have met with cases which have gone beyond their own fluctuating limits.

Dr. Murphy has so completely anticipated the objection which might be urged on the ground of the menstrual function being possibly suspended from some hidden morbid cause one or two months before the actual date of conception, that it is scarcely necessary to make any remarks upon it. If it is to be admitted under these circumstances, it would be only equally just to admit that in any given case the ordinary and so-called fixed period, calculated from the cessation of menstruation, is based on a fallacy. Thus, it might be urged the menstrual function may continue for several intervals after conception. A woman may have conceived one or two months before the cessation of the menses, and thus a corresponding addition should be made to the ordinary period. Dr. Murphy observes of his cases, that periodic discharges resembling the menstrual took place during pregnancy: in one case up to the time of quickening, and then ceased in another up to the eighth month after conception; in a third throughout the whole period of pregnancy. In all these cases the discharge was described as being in every respect similar to the menstrual. This view of the question may appear to prove that no reliance can be placed on the time of the cessation of the menses as evidence of the duration of pregnancy; but if, as in case No. 184, a married woman has been perfectly regular for four years previously, the sudden cessation of the discharge without any morbid cause to account for it, would assuredly furnish evidence of the strongest possible kind. Its continuance may, on the other hand, give rise to error, and lead to the period being unduly shortened. In the Gardner Peerage case, the Attorney-General was quite willing to rely upon the cessation of the menstrual discharge as a
good criterion of the duration of pregnancy, when by such a mode of calculation this was not made to exceed forty weeks! But this condition must be either taken, or rejected altogether, as evidence: if taken, we have no right, in alleged protracted cases, to refer the suppression to disease, for the sake of shortening the period,—when in ordinary cases we do not refer its continuance to disease, because it would tend to lengthen it: if rejected, it would be in the highest degree unjust not to give to a claimant the beneficial presumption of his having been born legitimate, when the cases adduced in evidence against his claim are actually based upon a precisely similar mode of calculation!

It is impossible to admit that the whole of the protracted cases recorded by different observers, have depended upon some mistake being made in the calculation of the period, since this calculation was founded on the same principles as those adopted in cases of ordinary pregnancy. Hence, if there was a mistake in the one case, there would be in the other: if an error in the exception, there would be an error in the rule. Either the average term of pregnancy is wrongly calculated by most accoucheurs at the thirty-eighth or fortieth week, or it is rightly calculated to extend occasionally to the forty-fourth, or, admitting Dr. Murphy’s case, to the forty-sixth week. But even setting aside the palpable answer to an objection of this nature, some of the cases observed were instances of impregnation from a single intercourse; and making due allowance for the interval for conception, the general inference would not be affected, and no fallacy could have arisen in these cases from mistakes regarding menstruation.

Since the publication of the early editions of this work, some instructive papers on the duration of pregnancy have been published by the late Dr. Reid. (See Lancet, Sept. 3 and 10, 1853, pp. 265 and 285.) The conclusions to which Dr. Reid has arrived are adverse to the views of Dr. Murphy regarding the great duration of pregnancy. He states truly, that an accidental arrest of the menstrual discharge may take place for three, four, or many successive periods, while impregnation may have occurred at any time during this suspension. Under these circumstances, a calculation based on the date of the suspension of the discharge would, of course, be erroneous; and “the number of days which elapse after the last menstrual appearance, is not, therefore, any proof of the real extent of gestation in otherwise doubtful cases.”

In one case which he reports, labour occurred 294 days after menstruation, but 278 days after intercourse; in a second, 287 days after menstruation, but 276 days after intercourse; in a third, 281 days after menstruation, but 277 days after intercourse; and in a fourth 294 days after menstruation, but 279 only from the earliest possible time of conception. It will be perceived that while the dates from intercourse varied slightly, those from menstruation varied considerably. In a case reported
by Dr. Montgomery, the last menstruation was on the 18th of October. Impregnation (intercourse?) took place on the 10th of November, and parturition followed on the 17th of August. The interval between insemination (intercourse) and parturition was thus 280 days, and between the last menstruation and parturition it was about three weeks more, namely, 303 days.

Dr. Reid's conclusions, derived from the facts and cases published in his papers, present the recent views of an experienced observer on this much disputed question: They are, 1. "The duration of pregnancy is not altogether a fixed period. It varies somewhat in the human female as it does in the lower orders of animals. 2. This deviation, however, is not to any great extent. The only certain data for calculation are those dependent on the known time of conception (of intercourse). 3. The average duration of the pregnant state, when calculated from this event, is about 275 days, or it may have a range of from 270 to 280 days. 4. There is no full or satisfactory evidence of gestation having been prolonged beyond 293 days. 5. The Code Napoleon, which allows 300 days, and the Prussian law, which fixes the ultimum tempus at 301 days, may be regarded as liberal. 6. The menstrual period must generally serve as our guide in default of some exact knowledge. It is, however, often fallacious, and is only a means of approximation as to the probable time of parturition. 7. The fortieth week after the last appearance is the most likely period, and the forty-first the next."

Dr. Duncan (Ed. Monthly Journal, 1854, vol. ix. p. 290) draws the following conclusions regarding the duration of pregnancy. 1. That the interval between conception and parturition (the real duration of pregnancy) has not been exactly ascertained in any case. 2. That the average interval between insemination (intercourse) and parturition (commonly called the duration of pregnancy), is 275 days. 3. That the average intervals between the end of menstruation and parturition, have no standard length, but vary within certain limits. 4. That while absolute proof of the prolongation of real pregnancy beyond its usual limits is still deficient, there is evidence to establish the probability that it may be protracted beyond such limits to the extent of three or even four weeks.

It will be perceived from the conclusions drawn by Dr. Reid that he admits a variation of 23 days, i.e. from 270, the shortest period, to 293, the longest known to himself from a single intercourse. (See ante, p. 610.) There appears to be no reason why the variation should not be even greater than that which is here assigned, and why the duration of pregnancy should not extend occasionally to 296 and 301 days. (See cases, ante, p. 627.) It is merely a question of individual experience. An accoucheur who admitted a variation of 23 days, and who had known gestation to be protracted to the 293rd day after intercourse, would
hesitate to pronounce a child illegitimate merely because it had been born on the 296th, or the 300th, day after possible access of the husband. There is no doubt a limit to gestation, but it is not in our power to fix it; hence we find obstetric writers of repute adopting periods which have no point of agreement among themselves. Some stop short at 280 days; others, like Dr. Reid, fix the maximum yet known at 293 days. Dr. Murphy allows from his experience at least 324 days; and Dr. Meigs considers that gestation may be continued to twelve months, or 365 days. (Obstetrics, the Science and the Art, 1849, 194.) The fact is, the term has not yet been fixed even approximately by medical science: hence, in a disputed case, other circumstances must be looked to in order to lead to a safe decision. It is at present hopeless to reconcile the conflicting medical opinions which exist on the subject of the duration of pregnancy in the human female. There is, indeed, only one point on which all modern observers agree, namely, that the period cannot be limited to a certain number of days, but that it is liable to variation according to numerous circumstances.

It has been already observed (ante, p. 613) that the date of intercourse does not furnish us with the date of conception, and according to some authorities all evidence connected with the function of menstruation is untrustworthy. In spite of these objections the menstrual period must generally serve as our guide in default of more certain criteria. It is, however, a curious fact, and one which the mind of an acute lawyer will not fail to appreciate, that the date of the cessation of the menses is taken as a guide (in married life with constant intercourse), by some physicians, so long as gestation does not extend beyond 280 days; while supposing it to extend to 300 days, they will assume that some other cause must have led to an earlier suppression, and thus to an error in the calculation! There may be no more evidence of suppression from a morbid cause in the one case than in the other, and the period of 280 days may be as much based in error as the period of 300. It is strange, that clever writers, who adopt this mode of making facts square with an hypothesis, do not perceive that they must, in fairness, either reject altogether the evidence derived from the cessation of the menses, or admit it adversely to their own views, in cases in which the facts connected with the cessation have been as carefully observed and recorded by others as by themselves.

Period of gestation not fixed by law.—In all cases of contested legitimacy, the question respecting the period of gestation, when it arises, is left entirely open by the law. No period has been fixed within which, or beyond which, a child, if born in wedlock, will be presumed illegitimate. The decision of a Court of law would be founded, quod the duration of pregnancy, on the opinions of experienced practitioners selected for the occasion, and each case
would be decided on its own merits. Precedents can have but little influence on these occasions; because a Court may think fit to pronounce illegitimate, on non-medical grounds, a child born in the thirty-eighth week of gestation; while it may decide that another was legitimate that had been born in the forty-third week. By some law authorities forty weeks are set down as the “ultimum tempus pariendi”—but as the period of human gestation is wholly independent of any legal dictum, it is not the custom of Courts to act upon this as a rule. Nevertheless, it is clear that in some cases the law must interpose, and pronounce for a reasonable limit. In the case of Cotterall v. Cotterall, decided in the Consistory Court, July 1847, the husband had proceeded against the wife for a divorce on the ground of adultery. The main proof was based on the fact, that in order to have been the child of the husband, it must have been born after twelve months’ gestation. The husband had left his wife in New South Wales, and was absent for that period of time without possibility of access. Dr. Lushington, without entering into the question of protracted gestation, upon proof of this allegation, at once pronounced for the divorce. Such a duration of pregnancy is not supported by any known facts, and is altogether opposed to medical probability. In a recent affiliation case, before Mr. Selfe at the Thames Police Court (Oct. 1857), proof was afforded that the putative father had been absent from England eleven months and six days before the child was born, and on this evidence the case was at once dismissed.

In two instances, children have been pronounced legitimate, which were born, the one in forty-one weeks and three days, and the other in forty-one weeks and four days, after the death of the husband. In the following case (Auderton v. Gibbs, 1834), the Vice-Chancellor decided that a child born ten months, or about forty-two weeks, after intercourse with the husband, was legitimate. A verdict had been already returned establishing the legitimacy of the plaintiff; and an attempt was now made to set this aside, among other grounds, upon the plea that the child was illegitimate because it had been born at so long a period after possible access. It appeared that the mother of the plaintiff for some time before and at the period of the birth had been living in adulterous intercourse; and that about ten months before the birth of this child she had had a private interview with her husband, when it was assumed that there had been access, but the parties did not meet afterwards. Before the adultery, they had lived together two years without having had issue, and in the present instance the child was born after a period of forty-two weeks—facts which were considered to establish its illegitimacy. The opinions of Sir Charles Clarke and other medical men were adduced at the trial, and these limited the extreme period of gestation to forty weeks; but they at the same time declared that
the subject was involved in darkness and uncertainty. The Vice-Chancellor considered that the jury at the trial had given a proper verdict by finding for the plaintiff's legitimacy. The jury were not to decide by whom the child had been begotten, but whether it could by any possibility be the child of the husband. With respect to the period of gestation, there was no difficulty. Sir Charles Clarke, and other authorities, confessed that the subject was involved in darkness and mystery; and that the Faculty of medicine knew nothing certain about it. There was no positive evidence of the exact day on which the child was born, nor on which the interview between the husband and wife took place. Therefore this would allow of the period of gestation being reduced to about forty-two weeks or less. The legitimacy of the plaintiff was in his opinion legally established. From this case it will be seen that a child may be affiliated on the husband, although the wife may be living in adulterous intercourse with another person.

Gardner Peerage case.—This well-known case came before the House of Lords in 1825; and a full report of it has been published by Dr. Lyall. (Med. Evid. in Gardner Peerage Case, 1827.) Alan Legge Gardner, the son of Lord Gardner by his second wife, petitioned to have his name inscribed as a peer on the Parliament roll. The peerage was, however, claimed by another person, Henry Fenton Sadis, who alleged that he was the son of Lord Gardner by his first and subsequently divorced wife. It was contended that the latter was illegitimate; and in order to establish this point, the evidence adduced was partly medical and partly moral. Lady Gardner, the mother of the alleged illegitimate child, parted from her husband, on board of his ship, on the 30th of January, 1802. Lord Gardner went to the West Indies, and did not again see his wife until the 11th of July following. The child whose legitimacy was disputed was born on the 8th of December of that year. Therefore, the plain medical question, taking the extreme view, was, whether a child born 311 days (forty-four weeks and three days) after intercourse (from January to December), or 150 days (twenty-one weeks and three days) from July to December, could be considered to be the child of Lord Gardner. If these questions were answered in the affirmative, then it followed that this must have been either a premature or a protracted birth. There was no pretense that it was a premature case, the child having been mature when born. The question then was reduced to this—Was this alleged protracted gestation of 311 days from the date of intercourse consistent with medical experience? Many medical witnesses, comprising the principal obstetric practitioners in the kingdom, were examined on this point. Their evidence was very conflicting, but a majority concurred in the opinion that natural gestation might be protracted to a period which would cover the birth of the alleged
illegitimate child. On the moral side of the question, it was
clearly proved that Lady Gardner, after the departure of her
husband, was living in open adulterous intercourse with a Mr.
Jadis; and on this ground Lord Gardner obtained a divorce
from her after his return. He subsequently married a second
wife, by whom he had the claimant, Alan Legge Gardner. It
was contended that the counter-claimant was really the son of
Lady Gardner by Mr. Jadis. The decision of the House was, that
this claimant was illegitimate; and that the title should descend
to the son of the second Lady Gardner.

The decision appears to have been chiefly based on moral cir-
cumstances; for had not the first Lady Gardner been living in
open adulterous intercourse at the time of her husband’s de-
parture, it is highly probable, from the medical evidence bearing
that way, that the legitimacy of the child would have been allowed.
Again, supposing the child had been born two or three weeks
earlier, the question would have resolved itself into this—who
had begotten the child?—the husband or the adulterer. This
could not have been decided, and then, probably, as in the more
recent case of Anderton v. Gibbs (supra, p. 633), the rule of law
would have pronounced the husband to have been the father. The
House, by its decision, must have considered that the medical
opinions, without cases to support them, could not be safely re-
ceived. It is obvious that the possibility of gestation being pro-
tracted must stop somewhere, and the Court probably thought
that they had here reached that point. Morally speaking, the
decision could not be impugned; but medically speaking, it
was incorrect; inasmuch as a Court of law never pretends to
settle who begat a child, when the pregnancy might by any pos-
sibility be ascribed to the husband or an adulterer. The House
of Lords, however, here decided that the adulterer begat the
child; and by implication their decision involved this medical
point,—that it is quite impossible a husband can be the father
of a child born forty-four weeks and three days after intercourse!
No case was adduced to show that so long a gestation had ever
been known to occur; for, as it has been already remarked, the
mode of calculation adopted in Dr. Merriman’s cases rendered
them unavailable as evidence. That in a medical point of view
the decision of the House of Lords, so far as it related to pro-
tracted gestation, was erroneous, must now be apparent; for
while their Lordships did not directly come to a resolution that
the one claimant was illegitimate, because he could have been
born only after 311 days’ gestation, they decided that the other
claimant was the only son and rightful heir of Lord Gardner.
A reference to the cases reported at p. 627, ante, will show that
gestation may be protracted to a period beyond that denied
to be possible on this occasion. Of the seventeen medical
witnesses examined, five supported the opinion that the duration
of human utero-gestation was limited to about nine calendar months, i.e., from thirty-nine to forty weeks, or from 273 to 280 days; or, strictly speaking, from 270 to 280 days; one of its witnesses, indeed, said from 265 to 280 days. These gentlemen of course gave their negative to the possibility, unless by miracle, that Henry Fenton Judis, alias Gardner, could have been the product of a 311 days' gestation. On the other side of twelve medical gentlemen who seemed to agree with respect to the above-mentioned period as the natural term of gestation, most of them maintained the possibility of pregnancy being protracted to nine and a half, ten, or eleven calendar months, and of course to 311 days—the alleged term of gestation at which the counter-claimant was born; and thus they admitted the possibility that Mr. H. F. Judis, alias Gardner, might be a ten and a half months' child. (Lyall's Med. Evid. on the Dur. of Pregm., &c. p. vii.) The conclusion at which the majority arrived appears to have received confirmation from the occurrence of several cases recorded by persons of repute, who appear to have taken every precaution to guard against inaccuracy (ante, p. 627). All the adverse witnesses on this occasion appear to have assumed that the date of intercourse was the date of conception: while from physiological researches, since made, conception may not take place until a week after intercourse; hence the time might have been reduced by a week (ante, p. 613). This would have made the period of actual gestation 314 days. In the United States a larger extension of the term has been allowed, than that which was considered impossible in the Gardner peerage case. A case has been decided in favour of the legitimacy of a child, in which gestation was protracted to 317 days, or forty-five weeks and two days. (Commonwealth v. Porter; Amer. Journ. Med. Science, October, 1845, p. 383; see post, p. 637.)

Evidence from the state of the child.—In protracted births it is not observed that the child is more developed, or of larger size, than at the usual period. In one of the supposed longest cases of protracted gestation on record (324 days) the child was not above the average size, although, when Dr. Murphy saw it, six months afterwards, it was unusually large and fat for a child of that age. (Obstetric Report, 1844.) This would lead to the inference, that when a child has reached a certain stage of development it ceases to grow; a view which is borne out by the observations of Dr. Rütel. (Henke, Zeitschrift, 1844, p. 247.) This gentleman has not remarked that the size of a child increases in proportion to the length of gestation. In protracted human and animal gestation the offspring is not remarkable for size and weight. In both cases robust mothers have had small children, and small mothers strong and sometimes unusually large children.

The following case (Luscombe v. Prettyjohn, Exeter Summer
Ass. 1840) will show how unsettled legal decisions are upon these points; and that disputed questions of gestation are sometimes decided without medical evidence, although there are few instances in which it is more urgently required. An action was brought against the defendant, by a farmer, to recover compensation for the loss of his daughter's services. It was alleged that the defendant had seduced her, and that she was delivered of a child of which he was the father. He denied that the child was his; among other reasons, on the ground that it was born two hundred and ninety-nine days, or forty-two weeks and five days after intercourse. No medical evidence was called to show that gestation might be thus far protracted; but the judge, in summing up, is reported to have made the following observations:—"Upon the evidence it was almost impossible that he (the defendant) was the father. Supposing that she (the woman) were right, that would place the birth at nine calendar months three weeks and five days." [The last meeting between the parties was had on the 9th of February, and the child was born on the 5th of December, 1838, which is equal to an interval of 299 days.] After adverting to some medical authorities relative to gestation, he said:—"He would rather believe that she had yielded to some other attempt on her chastity, than that so wide a departure from the usual course of nature had taken place!" The jury did not concur in this view, and they returned a verdict for the plaintiff, thereby pronouncing an opinion, which is well borne out by medical experience, that the defendant might have been the father of the child, although forty-two weeks and five days had elapsed since the last access. (Lancet, Aug. 1840.)

Had the verdict been the other way, there would have been fair ground, medically speaking, for a new trial; for the summing up was undoubtedly made on an entirely mistaken view of medical doctrines. It amounted to this, that the chastity of every married woman who bears a child in the forty-third week of pregnancy after the absence or death of the husband, is to be impeached,—and the legitimacy of her child is to be set aside on bare proof of the fact!

In a well-marked instance of gestation from a single intercourse, noticed by Dr. Reid, the interval was 293 days,—only six days earlier than the period here pronounced to be incompatible with legitimacy; and by referring to the cases of Drs. Rigby and Merriman, it will be seen that the periods of gestation from a single intercourse have varied to a much greater degree than the two here placed in comparison. This shows the risk to which the decision of such questions is exposed, when medical evidence is not called for on matters so strictly professional. The following case, which was tried in the United States, in January term, 1844, furnishes a contrast to that just quoted. (The Commonwealth v. Porter: Cambria county Pa.) The facts were some-
what similar. The defendant was indicted for fornication and bastardy. Prosecutrix, aged 23, stated that she had had intercourse with the defendant on the 24th September 1842, and with no other person before or subsequently. She was delivered of a child on the 7th August 1843,—i.e. 317 days, or after forty-five weeks and two days’ gestation; she swore that the defendant was the father of the child. The menses ceased about three weeks after intercourse, and they only appeared again slightly about five weeks before the child was born. At this time she had pains, which continued more or less until her delivery. She first knew that she was pregnant three or four weeks after intercourse. The defence was, that from the period of time which had elapsed, the defendant could not have been the father of the child. He, therefore, merely proved his absence, and that he did not return until after the birth of the child. No evidence was adduced to impeach the character or conduct of the female. It was proved that she had always borne a good reputation, and that she had been seduced by the defendant under promise of marriage. Dr. Rodrigue deposed, that, in a practice of nineteen years, he had attended some hundreds of cases of midwifery; and the longest period of gestation he had known was ten months. He considered the pains described by prosecutrix to have been the commencing pains of labour. The Court charged the jury strongly in favour of the medical testimony on protracted gestation, and they returned a verdict of guilty, thereby finding that the defendant was the father of the child. It transpired that a wife of one of the jurymen had during one pregnancy gone ten months. (Amer. Jour. Med. Sciences, Oct. 1845, p. 338.) Dr. Rodrigue, who reports this trial, states that a case subsequently came to his knowledge, in which gestation continued for a period of 320 days.

It would appear that the question of protracted gestation is frequently raised in the United States under these circumstances. Another case of bastardy (The Commonwealth v. Hooper) was tried in May 1846, in which the alleged duration of pregnancy must have been 313 days, or 44 weeks and five days. The prosecutrix deposed that she had had intercourse with the defendant on March 23rd, 1845, and not subsequently,—a fact established by the evidence; and the child, a large healthy male, was proved to have been born on the 30th January 1846. Twelve physicians were examined on the trial, and, as usual, they differed from each other. Some regarded it as possible, but not probable, that gestation might be so protracted as to reach 313 days. Various medical works were quoted on the subject. The Court charged the jury that, although unusual and improbable, this length of gestation was not impossible; and they returned a verdict finding that the defendant was the father of the child. (Dub. Med. Press, Nov. 4th, 1846, 296.) In the case of Dyson v. Dyson (Vice-
Chancellor's Court, Feb. 18, 1852), it was proved that the husband left his wife in Madeira, in Feb. 1848, that she returned to England in the August following, and the child whose legitimacy was contested was born on the 8th Jan. 1850. It was contended that this was a case of protracted gestation, and the evidence of several medical men to the effect that gestation might be protracted for 330, or even 336 days, was quoted in support of this view. In this case there was a period of 336 days. The Vice-Chancellor, having referred to the Gardner Peerage case, declined to make a decree in favour of the legitimacy of the plaintiff. (Legal Examiner, Feb. 21, 1852, p. 93.)

In extra-uterine pregnancy, the fetus may be carried for many years. Dr. Craddock relates a case, in which gestation was thus protracted for the long period of twenty-two years. (Phil. Med. Exam., May 1846, 286.)

*Mistakes in the mode of computation.* — Great mistakes have arisen in the calculation of the period of gestation by the use of the word month—some intending by this *lunar*, and others *calendar* months. Nine lunar months would be equal to two hundred and fifty-two days, while the average of nine calendar months would be two hundred and seventy days—the latter period varying according to the particular months of the year over which the pregnancy may extend. To prevent such mistakes, or that misunderstanding of evidence which has so frequently arisen, it would be advisable that medical witnesses should always express the period of gestation in weeks or days. It would be also proper to adopt the plan of always commencing the calculation from the period of the last cessation of the menses, rather than from two weeks later. The latter rule is often followed, and this discrepancy creates confusion.

It will be seen by the foregoing cases and remarks, that in these suits of contested legitimacy the general practice consists in establishing possibility of access on the part of the husband; —when this is proved, the medical question arises, whether the term of gestation falls within those limits assigned by the best medical experience. Legitimacy has been allowed where gestation was probably protracted to the *forty-third week* (Anderton v. Gibbs, p. 633); and in the United States, where it extended to *forty-five weeks* and two days (Commonwealth v. Porter, p. 638). It has been disallowed in the English Courts, although probably on non-medical grounds, where it was protracted to *forty-four weeks* and three days (Gardner Peerage case, p. 634); in one case (judicially) because it had extended to *forty-two weeks* and five days (p. 637); and in another (Dyson, supra), because it had extended to *forty-eight weeks*.

*Cases in reference to proof of access.* — In the case of *Cope v. Cope* (North. Spring Circ. 1833) an action was brought by the plaintiff, for his share of a legacy, to a part of which he declared
himself entitled, as being the son of the deceased testator's brother. There was no doubt that the plaintiff was born during lawful wedlock; but it was contended that he was an illegitimate child—therefore it remained with the defendants to establish his illegitimacy by evidence. The defendants rested their case, 1st, on the entry in the parish register, which represented the plaintiff to be an illegitimate child; 2ndly, on non-access between the husband and wife. The husband, having separated from the wife, went to reside at about fourteen miles' distance from her. He was absent for several years; but it was contended that he was always within a short distance of the wife. During his absence the wife formed an illicit connection with another man, and at this time the plaintiff was born; but it was rendered probable that the husband had visited the wife before and after the birth of the child. It appears that both the mother and the husband regarded this child as illegitimate; and an attempt was made, on the part of the defendant's counsel, to put in declarations to that effect; but the Court interposed; and Alderson B. said—"Lord Hardwicke had decided that the mother could not be allowed to give evidence on such a point, as she could not discharge the husband of the birth of the child; and à fortiori the husband could not be permitted to discharge himself. Lord Mansfield and Lord Hardwicke had both decided that illegitimacy could only be proved by the fact of there being no marriage, or by the proof of non-access; and it was held, on the grounds of decency and morality, that the parties themselves should not be allowed to prove non-access after their marriage." In summing up, he further observed, "that if a child be born in marriage during the lifetime of the husband, that child in law is presumed legitimate. The plaintiff in this case is the youngest child, and was born after four other children, and during the lifetime of the reputed father; and he is in law, therefore, legitimate, unless the fact were proved, which it was for the jury to decide upon, viz. that the husband had not had opportunities of access. If a husband have access, and others at the same time have criminal intimacy with his wife, still a child born in such a case is legitimate in the eye of the law. But if the parties are living separate, and the wife is notoriously living in open adultery, and the husband have opportunities of access, yet under such circumstances, it would be monstrous to suppose that he would avail himself of these,—then the legitimacy of a child, as born, could not be established." The jury returned a verdict for the plaintiff, finding that he was legitimate.

From this case we learn what kind of evidence the law requires in order to establish access or non-access. To defeat the legal presumption of access, when husband and wife are living near to each other, something more than mere probability of non-intercourse must be adduced. It is true, that in this case, the
wife, while separated from her husband, was living in open adultery; but non-access of the husband was far from being clearly established. On the contrary, access was rendered probable by evidence:—therefore, a verdict was returned, finding the plaintiff legitimate. It will be seen that very little value is set on baptismal registries, as evidence of legitimacy, or the contrary; also that the declaration of a parent is not in this case received by a Court as evidence of the illegitimacy of the reputed offspring, although in bastardy cases the statement of the mother is received as evidence against the putative father.

I am indebted to the Lord Justice Clerk for the subjoined remarks on the decision in this case:—“Acts of the mother, showing that she acknowledged and treated the child as the offspring of the adulterous connection, cannot be rejected. Then, why should her declarations be rejected? If the presumption had been that all children born in wedlock were to be taken in all cases, without inquiry, to be legitimate, then, of course, the mother’s declarations ought to be rejected, and there would be no inquiry at all. But that is not the state of the law. It is true that the mother’s declarations may be open to the remark, that she may desire to please her paramour by ascribing the child to him; but such and similar grounds of observation on her testimony are not sufficient reasons for rejecting peremptorily her declarations on the broad ground above stated. It may then, I understand, be doubted whether the rule above laid down would be enforced so absolutely; and therefore medical men, if aware of the circumstances in which the parties are living, should not fail to attend to all that is stated or passes before them, as to such matters.”

The case of Morris v. Davis (1830) was a suit of contested legitimacy, which had been pending for eighteen years before the Courts; and which was finally left by both parties to be disposed of by the judgment of the Lord Chancellor, on the facts and on the law of the case. The plaintiff was the son of a Mrs. Morris, and claimed to be the son of Mr. Morris; but it was contended that, although born in wedlock, he was illegitimate. The husband and wife had voluntarily separated; but lived for many years within a short distance of each other. The wife was living with an adulterer; and fourteen years after the separation, this child, the plaintiff, was born. The wife saw her husband occasionally, but concealed the birth of the child from him. The man with whom she was living considered it, and always treated it, as his own; and Mr. Morris remained for seventeen years in ignorance of the birth, or even of the existence, of the child. His lordship having stated the law of the case, as already given, said the question was one of fact and not of law. There was an apparent difficulty in the case, owing to this,—that the parties, although separated, were proved to have met
occasionally:—there was, therefore, unquestionably opportunity of access:—but it so happened, that none of these meetings would correspond with the time requisite for the birth of the child, to render it legitimate. This fact, together with the general bad conduct of the mother, and her open adulterous intercourse, led him to pronounce that the plaintiff was an illegitimate child, and that he was not the son of Mr. Morris. This judgment was not opposed to the rule of law, nor was it founded upon a mere balance of probabilities, but entirely upon the facts of the case.

---

Paternity.

Chapter LIII.

Disputed paternity—evidence from likeness—Douglas peerage case—parental likeness—affiliation—posthumous children—superpetition in relation to legitimacy—circumstances under which it is supposed to occur—superconception—supposititious children—relation of the subject to feigned delivery and legitimacy.

Disputed paternity. Parental likeness.—It has been stated that the law does not pretend to determine who begat a child when it has been born during wedlock, and from circumstances might be the child either of the husband or an adulterer. But medical jurists have recommended that family-likeness should be looked to on these occasions,—not merely a likeness in feature and figure, but in gesture and other personal peculiarities which may have characterised the alleged parent. These are called questions of paternity: they seldom occur except in reference to cases of bastardy, and when they do present themselves, the evidence thus procured, even if affirmative, is properly regarded as only corroborative. In the Townshend Peerage case, (House of Lords, May 1843) a presumption based on family likeness was admitted by their lordships. The party whose legitimacy was in question was sworn by one of the witnesses to bear so strong a likeness as a child to the alleged adulterer, that he should have known him among five hundred children.

The proceedings in the Douglas Peerage case (1767–9) also show that evidence of this kind is occasionally of some importance. This peerage was claimed by Archibald Douglas—the survivor of two brothers after the death of the alleged
parents, Sir John and Lady Douglas. The claim was disputed, on the ground that the appellant and his deceased brother were supposititious children. Evidence for and against the legitimacy of the claimant had been collected from every quarter, and after it had been most minutely sifted and criticised, the case came on for judgment in the Court of Session in Scotland on the 7th of July 1767. So important was the cause deemed, that the fifteen judges took eight days to deliver their opinions. The result was that seven of the judges voted in favour of the identity or legitimacy of Mr. Stewart and seven against it; the Lord President, who had the casting vote, agreed with the latter, by which Douglas, alias Stewart, was cast on the world without either name or estate, thus furnishing one among numerous instances that judges as well as doctors can differ with precisely the same facts before them. An appeal from this decision was taken to the House of Lords, by which the judgment of the Court of Session was reversed in 1769, and Archibald Stewart, or Douglas, declared to be the undoubted son of Lady Jane, the sister of the late Duke. Much stress was laid, in favour of the legitimacy of the children, on the fact that they closely resembled— the one Sir John, and the other Lady Douglas. The resemblance was said to be general; it was evident in their features, gestures, and habits. Lord Mansfield, in delivering judgment, made the following remarks, which comprise all that can be said on this subject. "I have always considered likeness as an argument of a child being the son of a parent, and the rather as the distinction between individuals in the human species is more discernible than between other animals. A man may survey ten thousand people before he sees two faces exactly alike; and in an army of a hundred thousand men, every man may be known from another. If there should be a likeness of feature, there may be a difference in the voice, gesture, or other characters; whereas a family likeness runs generally through all of these: for in everything there is a resemblance, as of feature, voice, attitude, and action." This kind of evidence has been strongly objected to from its uncertainty; and I am informed, on good authority, that it was in this instance much disputed whether one of the children did resemble Lady Douglas. It seems to have been generally admitted that the other child resembled Sir John Douglas. From this account, it will be seen that evidence from family-likeness is not strictly medico-legal,—it can be furnished only by friends and relatives who have known the parties well, and are competent to speak of the facts from personal acquaintance with them. It will also be apparent that the affirmative evidence in such cases will be stronger than that which is negative; for it could hardly be inferred that a person was illegitimate, because he did not resemble his parent.
Parental likeness may be occasionally indicated by colour or peculiarities belonging to the varieties of mankind, as of the intermixture of the Negro with one of the Caucasian variety. In such a case the evidence afforded becomes much stronger; and supposing that two men of different varieties have intercourse about the same time with the same female, the colour of the skin may enable a Court to determine the question of paternity. It is stated to have happened on more than one occasion, that a black woman has given birth at the same time to a black child and a mulatto; and Dr. Cunningham refers to a case in which a negress gave birth to twins, one a black and the other a white child. (Lancet, May 9, 1846, 525.) This was probably a case of superconception. (See post, p. 650.)

In the case of Stothard v. Aldridge (Bail Court, January 1836), the plaintiff sued the defendant for damages for the seduction of his wife. The defendant was a man of colour, and the child born of the alleged adulterous intercourse was proved by the medical witness to have been born coloured and with woolly hair. The husband and wife were both light. This peculiarity fixed the paternity of the child on the black defendant.

Personal deformities are not necessarily transmitted from parent to child; yet it would appear from the subjoined case, that a disputed question of affiliation has been settled on this principle. A woman alleged that a gentleman in whose service she had lived, was the father of a child of which she had been recently delivered. The solicitor, who appeared to support the affiliation, rested his case chiefly on the fact that the child had been born with five fingers and a thumb on the right hand, the defendant himself having been born with a similar malformation on both of his hands. It was argued on the other side, that the deformity might have arisen from the mother’s imagination, as while pregnant, she was constantly in the habit of seeing the defendant. The magistrates decided that he was the father of the child, and condemned him to pay the necessary expenses for its support. (Med. Times, March 6, 1847, p. 47.) It is very likely that the decision was here influenced by moral circumstances; for otherwise the defendant might have been the victim of a coincidence. Six-fingered children are, it is well known, born occasionally of five-fingered parents: and as the deformity existed only on one hand in the child, while it was on both hands in the parent, the medical proof that it was actually transmitted by generation was certainly not clearly made out. In some instances attempts have been made to fix the paternity of a child by the colour of the hair, but this evidence is far less conclusive than that afforded by the colour of the skin. In the case of Frazer v. Bagley (Feb. 1844), the wife of the plaintiff was alleged to have had criminal intercourse with the defendant, and the last two children were alleged to be the offspring of the
latter. The plaintiff and his wife had dark hair, as well as all the children with the exception of the two last:—these had red hair; and it was further proved that defendant had red whiskers and sandy hair. No particular stress was laid upon this evidence, but it was received as a kind of indirect proof. But little confidence can be placed on facts of this description, since red-haired children are often born to parents who have dark hair; and in one case the children born in wedlock were observed to have dark and red hair alternately.

Affiliation. — Questions of paternity are involved in those relating to affiliation. A party may allege that he is not the father of a particular child, by reason of certain circumstances upon which a medical opinion may be required. The necessary transmission of gonorrhoea or syphilis by intercourse, may thus become a medical question. In September 1844, a man was required, under the law of bastardy, to support two children alleged by a female to be his. The time of gestation was within nine months. The accused denied that he had had intercourse with the deceased, or that he could have been the father, since he was at the time under medical treatment for the venereal disease. The medical questions may therefore assume this shape:—1. Are these diseases invariably transmitted by intercourse? 2. Do they interfere with the act of procreation? Under common circumstances they must both be answered in the negative.

A singular case of bastardy is reported to have occurred in Appenzell, Switzerland. The question was, which of two persons, who had had intercourse with the same woman within a period of seventeen days, was the father of an illegitimate child borne by the woman. The Council to which the case was referred gravely resolved to postpone their decision until the features of the child were so far developed as to enable them to decide from paternal likeness. The equity of this difficult case would have been met by compelling each man to contribute to the support of the child! (Schneider's Annalen der Staatsarzneikunde, 1836, 1 B. s. 470.) The following, which is a more doubtful case, was the subject of a communication to the Lancet (March 13, 1847, 263). Two men, A and B, had intercourse, unknown to each other, with a young woman of delicate health; and after this had continued for some years, she was delivered of a female child nine calendar months and three days after sexual intercourse with A, and nine calendar months, less five days, after similar intercourse with B; or at the end of 279 days after intercourse with A, and at the end of 271 days after intercourse with B: that is, a period of eight days elapsed between the periods of intercourse of the two men, and the woman had no menstrual discharge in the meantime, and it is not believed she knew any other man. She went her full time, had a good labour, and produced a fine healthy girl; had a plentiful supply of milk, and
enjoyed better health during her pregnancy and suckling than any other time. The woman died, and the circumstances of the mixed intercourse having become known to A and B, they both refused to maintain the child. A contended that, as the woman was not delivered until nine months and three days after connection with him, it was physically impossible the child could be his. B contended, on the other hand, that 280 days, or not nine months, is the period of gestation; and that the child, having been born 279 days after connection with A, and on 271 days after connection with B, it was therefore probable the child was begotten by A. There was no perceptible likeness to either of the men in the child, but a marked likeness of the mother. It is obvious, from the remarks elsewhere made (ante, p. 610), that the two periods, 271 and 279 days, are comprised within the common range of gestation; hence there would be medical ground for affiliating the child to one more than the other. When two men have intercourse with the same female on the same day it is impossible to settle the paternity except by the accident of likeness. As in the former case, justice to the offspring and to each possible father required that they should have been both bound to support the child. In cases of affiliation under the law of bastardy the evidence of the mother, if corroborated, is received in support of a question of disputed paternity. Sometimes these cases are decided by the length of the period of gestation. A man may prove, or a woman may state, that the intercourse took place at such a remote period as to be inconsistent with the ordinary duration of pregnancy. On this point some remarks have been made elsewhere (ante, p. 627). In the United States it appears that very long dates are allowed in bastardy cases (ante, p. 638). In this country the tendency is to reject the evidence. In a case at Cheltenham (July 1853) the date of intercourse was proved to have been three hundred and nineteen days before the birth of the child. The medical evidence on the whole was in favour of this protraction—one of the witnesses having made two cases in which gestation was protracted to three hundred and ten days. The case was dismissed.

These questions of affiliation, when the interval is less than six or eight weeks, can rarely be determined by medical evidence. In a twin case, it would be only just that one child should be affiliated to each individual. In a recent case of affiliation, an attempt was made to set aside the order of a magistrate fixing the paternity on the putative father, on the ground that, as the intercourse was had, and the child conceived, in France, although born in England, it was removed from the jurisdiction of an English magistrate, and should be left to the French Court. The objection was properly overruled, and the alleged father was ordered to pay the usual sum for maintenance. The place of birth should properly fix the liability, as any other rule would have
too vague. From that which has been elsewhere stated (ante, p. 608.) the reader will perceive that in a given case intercourse might take place in Scotland followed by conception in England and birth in Ireland. So that there is a due relation between the date of intercourse and the date of birth no other proof is required.

Posthumous children.—It has been supposed, that a case involving a question of paternity might present itself on the marriage of a widow soon after the death of her first husband. If a child were born after the lapse of ten months, it might be a question whether it was a child of the first or second marriage—of the dead or the living husband; and although there might be no dispute concerning its legitimacy, yet it would be difficult to settle its paternity. Such a case appears hypothetical. In order that any doubt should exist, a woman must marry within, at the furthest, six weeks after the death of her first husband, or the birth of the child would fall beyond the furthest limit of gestation, so far as he was concerned. The customs of society are, however, a bar to such marriages; and admitting that a child was so born, and that it might be the offspring of either husband, then the fact of its having been born during the marriage of the second husband would presumptively fix the offspring upon him, unless it could be shown that there was no possibility of access on his part. If there were a supposed greater likeness to the first than the second husband, still this would not be allowed to defeat the legal presumption of the real parentage of the child. It appears to me, that evidence much stronger than this would be required for such a purpose. (See Henke, Zeitschrift, 1838, ii. 432.)

SUPERFETATION.

Superfetation in relation to legitimacy.—Most medico-legal writers, in treating legitimacy, have considered it necessary to introduce the subject of superfetation. By this we are to understand, that a second conception may at any time follow the first, and that gestation may go on to its full period in each case independently of the other, so that if a woman were impregnated when in the third month of gestation, she would bear the first child mature at the end of nine months, and the second child, also mature, at the end of twelve months, after the first conception. This subject has been said to involve “not only the conjugal fidelity of a wife, but the disposition of property, and much of the comfort and happiness of society.” Its importance to a medical jurist appears to me to have been here considerably exaggerated. So far as I have been able to ascertain, not only is there no legal case involving this question, to be met with in the judicial records of this country, but none, in reference to this state, is ever likely to occur which would create the least
practical difficulty. If we admit that a woman may, during marriage, present such an extraordinary deviation from the common course of nature, as to produce two perfectly mature and fully developed children, the one three or four months after the other, how can such an event be any imputation on her fidelity? Superception, if it occur at all, may occur as well in married life, during cohabitation intercourse, as among unmarried females. The following appears to be the only possible case wherein a medical opinion might be required respecting this alleged phenomenon. A married woman, six months after the absence or death of her first husband, gives birth to an apparently mature child, which dies. Three months afterwards, and nine months after the absence or death of her husband, she may allege that she has given birth to another child also mature: a medical question may arise, whether two mature children could be so born, that the birth of one should follow three months after the birth of the other,—or whether this might not be a case, by no means uncommon, of twin children, the one being born prematurely, and the other at the full period. (For a case of this kind, at two months' interval, see Med. Gaz. xxxvii. 27; and for another at eight days' interval, see the same journal, vol. xlvi. p. 227.) Mr. Brown has more recently published a case in which abortion of one fetus occurred at the third month, while the other attained the full period. (Assoc. Medical Journal, Nov. 11, 1858, p. 997.)

Admitting that both the children were mature, and therefore that it was a case of superstition, the first delivery must have taken place in the presence of witnesses, and it would then have been known whether another child remained in the uterus or not. If the two children were born within the common period of gestation after the absence or death of the husband, then their legitimacy would be presumed, until the fact of non-access were clearly established. The mere circumstance of their being apparently mature, and born at different periods, would per se furnish no evidence of their illegitimacy. On the other hand, if one or both of them were born out of the ordinary period, then, according to the evidence given, they might or might not be pronounced illegitimate. The law therefore appears to have no sort of cognizance of the subject of superstition as such: it is entirely merged in the question of protracted gestation, which has already been fully considered (ante, p. 625).

Super-conception.—Whether superstition can really take place or not, is a question which has given rise to much controversy. That one conception may follow another within a short period, and that twins may thus be the result of two distinct conceptions, is a probable occurrence. This, indeed, is what may be termed Super-conception. But when gestation has already gone to the second month, it has been hitherto considered highly im-
probable that there should be a second conception. In two cases, however, in which two men had intercourse with females within the period of seventeen and eight days respectively—cases favourable to super-conception,—there was, in each case, only one child, and the paternity was actually disputed. (See ante, p. 645.) According to Donné, there is a limit to this power of super-conception. He has found that the mucus secreted from the vagina of pregnant females, is, by reason of its great acidity, completely destructive of the existence of the zoosperms, and therefore renders the spermatic fluid unprolific. (See post, Sterility.) It does not appear, however, that the vaginal mucus becomes more acid at this period; but, according to Mr. Whitehead, the effect is due to this acid secretion not being partially neutralised, as in the unimpregnated state, by the alkaline mucous secretion of the uterus. (On Abortion, 406.) At what period of pregnancy the vaginal mucus begins to act destructively on the zoosperms, has not yet been determined; but further researches may show that we have in this chemico-physiological theory a complete answer to the old doctrine of superfetation.

In a paper published in the Association Journal, May 6, 1833, p. 398, Dr. Duncan, in referring to the occurrence of menstruation during the early months of pregnancy, considers that he has obtained anatomical proofs that this discharge may take place from the inner surface of the uterus after impregnation, and up to the third month of gestation. He believes that during this period super-conception may occur, and that this will satisfactorily account for all the cases of superfetation which are on record. We may suppose that the first child is born prematurely, but within the limits of viability; we thus gain two months; and if impregnation may take place between two and three months after one conception, we may thus have four or five months' interval between the births of successive viable infants. It is not therefore necessary to suppose that they have both been conceived at the same time. Until the mouth of the uterus is closed as a result of the development of an embryo, it is possible that conception may take place from intercourse subsequently to a previous conception. The exact period at which this closure occurs has not been determined; but according to Dr. Duncan the menstrual secretion may find its way through the mouth of the uterus for at least two months after conception. If this be the case, a second conception might occur two months after a first conception; but I am not aware of any facts to support this statement. It cannot be denied that super-conception may occur in cases in which two separate intercourses have been had within a few days of each other; and according to some, twins may be generally regarded as the result of this double conception at different periods. (Ramsbotham’s Obstet. Med. 500.)
Dr. Carter has reported the following case in the Philadelphia Medical Examiner. A negro woman, quite black, age 23, and good constitution, had borne three children previously to her last labour. She stated that in April 1848 she had had connubial relations with a white man, and on the following day with a black man. This was about a week or ten days before the cessation of menstruation. In the middle of February 1849 she was delivered of twins, one of the children (the first-born) being as dark as her children generally are, while the other was a mulatto. The woman believed that they were begotten by different fathers; and this is rendered highly probable by the difference in the colour of the skin. (Ed. Month. Jour., May 1850, 485. See ante, p. 64.) The reader will find several cases of a similar kind reported by Dr. Ramsbotham (Op. cit. 501).

Most cases of alleged superstitious motives are readily explainable on the supposition that the woman was pregnant with twins, one of which was born prematurely, and the other at the full term, or later. The following, reported by Dr. Möbus, of Dieben (Henke’s Zeitschrift der S. A. 1837,) will serve as an illustration. — A healthy married woman, about thirty-five years of age, was safely delivered of a girl on the 16th of October 1833. The child is described as having been well formed, and having been about all the signs of maturity. This woman, it is to be observed, had previously had several children in a regular manner. Soon after her delivery and the expulsion of the placenta, a feeling was noticed, on this occasion, something still moving within her. On examination, the mouth of the uterus was found completely contracted, and the organ itself so drawn up as to render it difficult to be reached: but the motions of a second child were plainly distinguishable through the parietes of the distended abdomen. Her delivery was not followed by the appearance of the discharges (lochia), nor by the secretion of milk. The breasts remained flaccid, and there was no fever. On the 18th November, thirty-three days after her first confinement, the woman, while alone and unassisted, was suddenly delivered of another girl, which, according to Dr. Möbus, was healthy, and bore no signs of over-maturity about it. The reporter alleges that this case most unequivocally establishes the doctrine of superstitution. The two births took place at an interval of thirty-three days, and the two children were, it is stated, when born, equals well-formed and mature; but Dr. Möbus did not see the second child until twenty-four hours after birth.

This appears to have been nothing more than a twin case, which one child was born before the other. Dr. Möbus considers, that the first child was born at the usual period of gestation, it being described as mature; and the other, thirty-three days after that period,—having been, in his view, conceived many days later than the first child. If, however, we imagi
that in this, as it often happens in twin cases, one twin was more developed than the other, and that the more developed was the first expelled; or that it is not always easy to compare the degree of development in two children, when one is born before the other and they are not seen together, we shall have an explanation of the facts, without resorting to the hypothesis of a second conception after so long an interval. As to the signs of over-maturity alluded to, they are not met with. If we are to believe authentic reports, a child born at the thirty-ninth week is not to be distinguished from one born at the forty-third or forty-fourth (ante, p. 636), and children born at the full period vary much in size and weight. A longer period may be required to bring the child to maturity in some women than in others; and in a woman with twins, it is well known that the two children may arrive at the same degree of maturity within different periods,—one requiring, perhaps, several weeks longer than the other for its full development.

Cases of abortion of one twin, the other remaining in utero, are by no means uncommon. In addition to those already quoted, two are referred to in the Ed. Med. and Surg. Journal (1839, p. 289). In one, abortion took place at three months, while the woman went to her full time and was delivered of a healthy child at nine months. In the second, one fetus was expelled at about four and a half months, while four months afterwards a full-grown child was born. In a third case, reported by Dr. Nevins, a woman was delivered of a premature fetus, and six weeks afterwards was confined of a full-grown child. (Med. Gaz. vol. xlv. p. 983.) Even under a malformation which might be supposed to be favourable to its occurrence, namely, the presence of a bilocular uterus, it has been found that impregnation has taken place in one cornu only. (See Med. Gaz. xix. 507.) A singular instance is, however, recorded in the same journal (xx. 508), where a woman, six months after marriage, bore a four months' child, and forty weeks after marriage, mature twins. On examination, the uterus and vagina were both found double, and each vagina had a separate orifice. Dr. Hofbeck, U. S., states that he met with a case in which a well-grown fetus of six months was simultaneously expelled with an embryo about six weeks old! (Med. Gaz. xlv. p. 87.) In the Medical Times (Jan. 31, 1852, p. 104) Dr. Foley has published the account of a case in which a mole was expelled from the uterus at an early period of pregnancy, while the female was delivered, about the usual period, of a living and well-formed although weakly child, which survived its birth three days.

Monstrosity and Superfetation.—A most extraordinary case of monstrosity, involving the questions of superfetation and paternity, is stated to have occurred at Alexandria in Egypt. A Fellah woman was delivered of a dicephalous monster at appa-
pregnancy is unsuspected), that a trick of this kind can be successfully practised.

A case involving a question of substitution (Hutchins v. Hutchins) was heard in the Vice-Chancellor's Court in May 1851. The amount of ingenuity required to perpetrate a fraud of this kind was only equalled by the skill with which the facts were exposed, and justice was ultimately done to a rightful claimant.

HERMAPHRODITISM.

CHAPTER LIV.

General Remarks.—The legitimacy of a child is open to be contested under other circumstances than those connected with the duration of gestation. The alleged parent may have laboured under physical incapacity; if a male, he may have been affected with impotency; if a female she may have laboured under sterility; and if either of these conditions be proved, the illegitimacy of a child will be established, although the alleged period of gestation may be comprised within the ordinary limits. The sexual conditions now about to be considered have also important bearings in relation to divorce, and occasionally to the civil rights of a child that may be the subject of the malformation. One of the most common and obvious causes of impotency or sterility is malformation of the sexual organs, to which species of monstrosity the term hermaphroditism is commonly applied.

SEXUAL MALFORMATION.

Owing to arrested development, during the growth of the fœtus, the sexual organs, which can scarcely be distinguished at the fourth month, occasionally assume an abnormal arrangement.
These organs appear to be at that time more or less mixed; and sometimes the male, and at others the female characters predominate. With this defective sexual development, the other peculiarities of the sexes are either wanting, or we find them more or less blended. When, therefore, the being has the characters of a male with malformation of the generative organs it is called androgyne — when the characters are those of a female with a like malformation, androgyne. There can be no difficulty in identifying such cases, and, according to the degree of malformation, a medical jurist can have no hesitation in pronouncing these subjects to be incurably impotent. The organs are commonly so defective as to be wholly unfitted for the functions of either sex. It is not meant to be said that it is in all cases easy to assign the sex, but this is of minor importance; — the main question is, whether the malformation be or be not such as to justify divorce, or the imputation of illegitimacy upon children claiming to be the offspring of these beings.

**Distinction of sex.**— The determination of sex in these cases of deformity has been considered to be necessary under certain circumstances; as when, for instance, a title or entailed inheritance of lands is in question. Lord Coke has stated that, according to the law of England, an hermaphrodite may be either male or female, and it shall succeed according to the kind of sex which doth prevail. Thus it is obvious, that the law will decide each case according to the special circumstances attending it: but it must not be supposed that the decision is so easy as Lord Coke's doctrine would imply. There are many cases in which neither sex can be said to prevail. The beings are positively neuter. The chief character of the male would consist in the presence of testicles, and of the female in the presence of uterus and ovaries. But in a case which occurred to Mr. Grigor, both the testicles and ovaries were wanting; there were no essential characters of either sex, and during life it would have been impossible to say whether this being was male or female. (Cottam's Monthly Journal, July 1845, 492.) In the same journal (page 531) is reported another case, in which notwithstanding the external resemblance to a female, the presence of one testicle in a scrotum showed that this individual was of the male sex. Yet this person passed for a woman until he had reached his 26th year! It is rare that there is external malformation without internal defect, and even when the female character preponderates in the person, it is not improbable that the uterus or the ovaries may be absent, or the former may be malformed. Such beings are not known to menstruate, and even if there be capacity for intercourse, they are permanently sterile. Sexual desires are, however, commonly absent.

When the subject is young, mistakes respecting the sex are more common than when it is advanced in life. So soon as the
period of puberty is past, certain changes take place in the configuration of the body, which may aid the medical practitioner in forming an opinion. Thus a grave tone of voice, the presence of a beard, the width of the shoulders, and narrowness of the pelvis will indicate, ceteris paribus, the male sex: while when these conditions are absent, and there is a rotundity of the members, with want of prominence in the muscles, and a development of the mamme, we may pronounce upon the female sex predominating. Although no testicles be apparent, still the being may be of the male sex, since it is well known that in persons otherwise well formed these organs occasionally do not descend to occupy the scrotum. Dr. Harris, of Clarkesville, has related a singular case, in which, although no testicles could be found, there was a short, but naturally formed penis, through which the being regularly menstruated! The female character predominated in the corporeal development, and there was the rudiment of a vagina. (Med. Gaz. xl. 562.) The fact that the being menstruated was here sufficient to assign it to the female sex. How easily mistakes may be made in the sex of young children is shown by a case which occurred to Mr. Terry, and is quoted in Cormack’s Journal (April 1845, p. 307). The child was christened as a female, and so considered by the parents for two months, when, owing to some defect in the passage of the urine, it was brought to Mr. Terry, and he found that there was malformation of the penis,—no vagina, a scrotum with one testicle down and the other descending. He therefore pronounced it to be a male, and its costume was altered accordingly. The presence of a beard and whiskers is usually considered to characterise a male, but the growth of hair on the chin and face is sometimes more profuse in females than in the generality of males. Dr. Chowne examined a female named Josephine Boisdechine on behalf of a man who was about to marry her, but who required a certificate as to the real sex of his intended wife! Dr. Chowne found nothing in her external conformation indicative of doubtful sex. The breasts were large and full, and the only resemblance to a male was in an abundant beard and very profuse whiskers. The upper lip was free from hair. (See Lancet, Oct. 11, 1851, p. 335; January 15, 1853, p. 66; Med. Times and Gaz., January 15, 1853, p. 71. Dr. Chowne has published a full account of this case in the Lancet for May 1, 1852, p. 421.) He has appended an engraving which displays the female beard and whiskers. It is stated that this female was born with a quantity of hair on her chin, and that at eight years of age the beard was two inches long!

In some cases an external examination will entirely fail in indicating the sex, and even the opportunity of an examination of the dead body may leave the case in doubt. An ingenious writer has laid it down that there are analogous organs in the
two sexes which are never found in the same subject, and the separate existence of which would enable us to determine the sex. These analogous parts are the penis and the clitoris — the scrotum and the labia — the testicles and the ovaries — the prostate gland and the uterus. This, however, is an artificial, and, as facts show, an incorrect means of distinction. If a penis could always be clearly distinguished from a clitoris, and a scrotum from the labia, the rule might be serviceable; but it fails where it is most required, i.e., in the mixed conditions. As to the other means of distinction, even if correct, they will only enable an examiner to form an opinion of sex in the dead, whereas it is during the life of a being that the law requires the aid of medical science in the solution of these questions. The reader will find, in the Medical Times and Gazette, an account of some remarkable cases of sexual malformation by Mr. Carling (Jan. 24, 1852, p. 84); by Mr. Fletcher (Feb. 7, 1852, p. 136); by Mr. Broadhurst (Feb. 21, 1852, p. 187; and by Mr. Waters, May 21, 1853, p. 538). Other cases, reported by Mr. Mann and Mr. Churchill, will be found in the Association Journal, 1853 (Aug. 19, p. 720, and Sept. 9, p. 799).

**Mixed cases.** — A case has been already mentioned in which neither testicles nor ovaries were found after death, and more than once instance has occurred in which both have been found,—a case of intermixture of the sexes or real hermaphroditism, physically speaking, but of course without the functional power of self-impregnation. The following case is mentioned by Briand:— The subject was about eighteen years of age when he died. The body was partly that of a male in configuration, and partly that of a female. An examination of the sexual organs, externally, led to no satisfactory diagnosis; and on inspection after death a testicle was found in what was supposed to be the left labium, with an epididymis and spermatic cord attached to it as usual; while on the other side were an ovary, Fallopian tube, and the rudiments of a uterus. The authenticity of this case was for some time a matter of dispute; but another, equally singular in its features, occurred to Prof. Mayer, of Bonn. This case clearly shows that such extraordinary deviations may be met with in nature. The person examined by Mayer died in 1832, at the age of 55. Different opinions had been formed during his lifetime respecting the sex by the first anatomists in Europe: some affirming that it was a male, while others contended that it was a female. This difference of opinion is sufficient to prove that an external examination does not always enable even a good anatomist to pronounce an opinion on the probable sex of the being. In the dead body was found, on the right side, a withered testicle, with a penis and prostate gland, as male peculiarities;—while on the left side was an ovarium, with a uterus, vagina, and Fallopian tube.
133.) It should be stated, that the general configuration of the body in this case was that of a female; but there was a duality of sex. The right half of the body was male, and the left half female.

Causes.—The causes of malformation of the sexual organs, like all other kinds of monstrosity, are involved in mystery. We know that in the early part of utero-gestation, the sex of a fetus cannot be distinguished; while, even when it has reached the fourth month, the genital organs are so similar that the sex can seldom be determined on inspection. Some organs or parts appear to be formed by equal and symmetrical portions, which gradually approximate and unite in the median line of the body. We observe this mode of union in the bones of the head, chest, and spine, as also in the various fissures (raphe) of the skin, which are the remains of a union between two equal and symmetrical parts of an organ, now become one. In regard to defects in organisation, it may be remarked that they almost invariably occur in or about some part of the median line; and they appear to proceed from a mere arrest of growth or development in those particular parts, either on one side or both, during the early stage of uterine existence. In this respect, the fissures sometimes observed in the palatine bones, in the palate itself, or in the lip—the openings occasionally noticed in the chest, diaphragm, anterior parietes of the bladder, as well as in the spinal canal, are precisely analogous in origin to the defective development of the sexual organs. There is nothing absolutely removed or lost, but there is an arrest of development; an opening, or fissure, which nature intended to be only temporary, becomes permanent by reason of an arrest of growth. In the evolution of the male genital organs, the part corresponding to the scrotum is at first always divided by a considerable fissure; and the penis and the clitoris having, at this period of life, much the same kind of physical exterior, the sexual organs cannot be well defined. Should this fissure in the male not be afterwards filled up, then we shall have the most common variety of sexual malformation,—the hermaphroditic form, with the male predominating. These observations are not, of course, applicable to those cases in which the sexes are positively mixed. In these instances there appears to be a separate sexual organisation on the two sides of the body, with an imperfect development of each set of sexual organs. According to Weber, there is in the prostate gland a rudimentary uterus in every male. (Baly and Kirkes' Recent Advances in Physiology, 1848, 112. Also papers by Dr. Knox, Med. Gaz., Nov. and Dec. 1843.)

One circumstance is worthy of note, namely, that sexual monstrosity appears occasionally to occur in the successive pregnancies of a well-formed female. Dr. Lever met with a singular instance of this in a female aged 28. She had given birth to four
children in three confinements, the first being a twin labour; both the children males; and in both there was an arrest of development of the sexual organs. On the third delivery the child was a male, and its sexual organs presented the same deformity as those of the twins. (Med. Gaz. xxxviii. 946.)

**Legal relations.** — These beings, owing to defective development, are impotent and sterile. Questions connected with the legitimacy of offspring, divorce and affiliation may, therefore, be raised with respect to them. This part of the subject will be considered hereafter. Sexual monstrosity is not a ground for depriving a being of the rights of inheritance except under peculiar legal conditions. Thus, a right of succession or inheritance to landed estate may depend upon the sex of the offspring, — as where, for instance, two children are born, the first an hermaphrodite, the second a well-formed male child. The parents die, and a title of nobility or lands may fall to the first-born male. Here the sex of the first-born must be determined before possession can be had. In a case of this kind, if medical evidence should establish that male peculiarities predominate in the first-born, the second child would be cut off. Again, if an estate were limited by entailment, as where it is settled upon heirs male or female of a particular family, the birth of an hermaphrodite, an only child, would create the legal necessity for a positive determination of the predominance of sex. So, if the hermaphrodite live but a few minutes after birth, and then die, the rights of persons may be subsequently much affected by the medical attendant having come to an opinion respecting its sex. Since we cannot determine under what circumstances litigation may ensue, it is always right in a doubtful case to observe the sex, and make notes on the spot, when a child thus malformed survives its birth but for a short period. The question of tenancy by courtesy, or the right of the husband to landed estate of which the wife was seized, will depend entirely upon the attention of the accouncheon to this point. (See Tenancy by Courtesy, ante, page 601.)

When these beings have reached adult age, other questions may arise with respect to them. According to an old law of France, an hermaphrodite was permitted to choose one sex, and thereafter compelled to keep it! Hermaphrodites, or sexual monsters, were formerly ranked with infamous persons; and it has been a grave question in our Courts, whether the calling a man an hermaphrodite was not such a libel or slander upon him as to render it a ground for a civil action. In a case reported by Chitty (Med. Jur. 374), the use of this term was held not to be actionable, unless it was proved that it had been attended with special damage. A dancing master brought an action against a party for calling him an hermaphrodite, and it was decided that it was not sustainable: — Because such a union of the sexes
cannot exist in fact, and every one must be supposed to know it; consequently the assertion could not be supposed to prejudice.

2. Because, admitting the possibility of such a double function, the party would be just as good, and perhaps even a safer dancing-master, than if only one perfect sex had been discoverable —consequently the words would not, in legal presumption, injure him in his profession or occupation!

I am indebted to a learned member of the bar for a note on the remarkable case of the Chevalier d’Eon. There was a great dispute concerning the sex of the Chevalier, and it came before a Court of Law on an action to recover a wager under the following circumstances (Da Costa v. Jones, 2d vol. Cowper’s Reports, p. 729). The plaintiff claimed of the defendant a sum of three hundred pounds. On the 4th October 1774, plaintiff paid to defendant seventy-five guineas, on the condition that he the plaintiff should receive from the defendant a sum of three hundred pounds, in case the Chevalier d’Eon should at any time prove to be a female. The cause was tried before Lord Mansfield, at Guildhall, and the jury found a verdict for the plaintiff, damages 300l., thereby affirming that the Chevalier was a female. A motion was subsequently made on behalf of the defendant to arrest the judgment, or at least to stay the proceedings, on the ground that the action could not be supported, as being upon a wager tending to introduce indecent evidence, and also as being one which materially affected the interest of a third person. The question thus raised on the motion was argued before the Court of King’s Bench, and the Judges unanimously agreed that the judgment must be arrested; the law not allowing wagers upon subjects leading to the introduction of indecent evidence (this being contra bonos mores), nor upon such subjects as are calculated to have an injurious effect upon the interests or character of a third person. Irrespective of this decision, the verdict was based upon what subsequently turned out to be untrue. The Chevalier was really a male, and not a female. He was carefully examined by Sir Anthony Carlisle, who satisfied all present of the perfect condition of the testicles. (See Paris and Fonblanque, i. p. 229.)

It would appear, from a singular case reported by Dr. Barry, that, in the United States, the rights of citizenship and the privilege of voting for members of Congress, have depended on the determination of sex. In March 1843, he was requested to examine the case of Levi Suydam, aged 23 years, a native of Salisbury, Con. At the exciting and warmly contested election of the spring of that year, almost everything bearing the semblance of the human form, of the male sex, is stated to have been brought to the ballot-box. It was at this time, and under these circumstances, that the above-mentioned person was presented by the Whigs to be made a freeman; he was challenged
by the opposite party on the ground that he was more a female than a male, and that, in his physical organisation, he partook of both sexes. The following was the result of the first examination by Dr. Barry. There was a mons veneris covered with hair in the usual way; an imperforate penis, subject to erections, and about two inches and a half in length, with corresponding dimensions; the dorsum of the penis was connected by the cuticle and cellular membrane to the pubis, leaving about an inch and a half free, or not bound up, and towards the pubic region. This penis had a well-formed glans,—a depression in the usual place of the meatus urinarius, with a well-defined prepuce and foramen. The scrotum was not fully developed, inasmuch as it was but half the usual size, and not pendulous. In the scrotum, and on the right side of the penis, there was one testicle of the size of a common filbert, with a spermatic cord attached. In the perineum, at the root of the corpora cavernosa, an opening existed through which micturition was performed: this opening was large enough to admit the introduction of an ordinary-sized catheter. Having found a penis and one testicle, though imperfectly developed, Dr. Barry, without further examination, gave it as his opinion, that the person in question was a male citizen, and consequently entitled to vote and enjoy all the privileges of a freeman.

On the morning of the first Monday in April (election day), Dr. Barry was informed that Dr. Ticknor would oppose Suydam’s admission on medical grounds. Suydam came forward; and Dr. Ticknor objected to him as a female, and therefore not entitled to vote. Dr. Barry then stated to the meeting, that, from an examination he had made, he considered the person in question to be a male, and requested that Dr. Ticknor might, with the consent of Suydam, retire into an adjoining room, and examine for himself. This was done, when Dr. Ticknor ultimately came to the conclusion that Suydam was a male. Suydam accordingly was admitted a freeman; and his vote was received and registered.

A few days after the election, Dr. Barry heard that Suydam had regularly menstruated. The sister of Suydam informed him that she had washed for him for years, and that he menstruated as regularly, but not so profusely, as most women. Suydam, when questioned, very unwillingly confessed that such was the fact. He was again examined by the two physicians, when the following additional particulars were elicited;—Said Suydam is five feet two inches in height, light-coloured hair, fair complexion, with a beardless chin, and decidedly of a sanguineous temperament, narrow shoulders and broad hips; in short, every way of a feminine figure. There were well-developed mammae with nipples and areolae. On passing a female catheter into the opening through which micturition was performed, and through which, he again stated, he had a periodical bloody discharge.
monthly,—instead of traversing a canal and drawing off urine, the catheter appeared to enter immediately a passage similar to the vagina, three or four inches in depth, and in which there was a considerable play of the instrument. He stated that he had amorous desires, and that, at such times, his inclination was for the male sex; his feminine propensities, such as a fondness for gay colours, for pieces of calico, comparing and placing them together, and an aversion for bodily labour, and an inability to perform the same, were remarked by many. Dr. Barry further learned from an old lady, who was present at the birth of Saydam, that on the second day after his birth, Dr. Delamater, who attended as accoucheur, made with an instrument the opening through which he had ever since performed micturition. (American Journ. of the Med. Sciences, July 1847.)

This was certainly an embarrassing case,—one to which Lord Coke’s rule for a decision, i.e. the prevalence of either sex, is hardly applicable. The presence of a penis and one testicle referred the being to the male, while the bodily configuration, and still more strongly the periodical menstrual discharge, referred him to the female sex. The right of voting might have been fairly objected to, because, while the female characters were decided, the organs indicative of the male sex are described as having been very imperfectly developed.

Dr. Hartshorne, the American editor of this work, quotes a case, in which an attempt was made by Dr. Gross, a surgeon in the United States, to destroy all sexuality, and thereby all rights of citizenship, in the case of an infant whose sexual organs were imperfect. (A report of this case will be found in the American Journal of Med. Sci., for Oct. 1852, and the Ed. Monthly Journ. for Jan. 1853.) The child, when seen by Dr. Gross, was three years of age, and had always up to that period been regarded as a girl, and in fact had been so pronounced at her birth by the accoucheur. At the age of two years she began to evince the taste, disposition, and feelings of the male sex: she rejected dolls and similar articles of amusement, and became fond of boyish sports. She was well-grown, perfectly healthy, and quite fleshy. Her hair was dark and long, the eyes black, and the whole expression most agreeable. A careful examination of the external genitals disclosed the following circumstances. There was neither a penis nor a vagina; but instead of the former there was a small clitoris, and instead of the latter a superficial depression or cul-de-sac covered with mucous membrane, and devoid of everything like an aperture or inlet. The urethra occupied the usual situation (in the female?) and appeared to be natural; the nymphae were remarkably diminutive, but the labia were well developed, and contained each a well-formed testicle quite as large and as firm as the organ generally is in boys at the same age. The hips, chest, thighs, and upper
EFFECT OF SURGICAL OPERATIONS.

extremities, were perfect. From this description it is pretty clear that the child was an androgyne, or there was imperfect development of the sexual organs, with predominance of those of the male. There was no indication of uterus or ovaries, nor any external peculiarity, except that which is frequently met with in hermaphrodites, in which there is an arrest of male development but no intermixture of the sexes. Dr. Gross considered that, for the child's future welfare and happiness, it would be better that it should have no testicles at all, than that it should retain them under such an imperfect development of the other organs. He therefore removed them by operation from the labia or divided scrotum, and had the satisfaction to find that they were perfectly formed in every respect, and that the spermatic cords were quite natural. The operation was performed in July 1849, and three years subsequently (in 1852) it was found that emasculation was complete, for the disposition and habits of the being had materially changed, and were those of a girl;—she was found to take great delight in sewing and housework, and she no longer indulged in riding sticks and other boyish exercises.

The reasons assigned for the performance of this operation—namely, the entire deprivation of sex, and thereby of any sexual feelings in after-life,—appear to me to be unsatisfactory. It is clear, from Dr. Gross's description, that this being was deprived of the rights and privileges of a male by the removal of the testicles. (See the case of Levi Suydam, ante, p. 660.) Dr. Gross appears to have contemplated the case only in a matrimonial point of view; but in a country where the rights of citizenship and power of voting for members of Congress are much valued, where they depend on direct proofs of sex, and are so strongly contested by opposing parties,—it is a serious question whether he has not here struck a severe blow at the political rights of these beings, in thus wilfully destroying the physical evidence of the male sex! In this country it might be a question whether he had not rendered himself liable in damages for thus tampering with the laws of nature.

Concealed sex.—It is almost superfluous to say that in some cases sex cannot be determined by the dress, appearance, or even voice of the individual. Cases in which males have passed for many years unsuspectedly as females, and vice versa, have been numerous. In some instances the secret has been disclosed only by death. Facts of this kind belong rather to the annals of imposture than to those of medical jurisprudence. A somewhat singular case of this description, that of Eliza Edwards occurred to me in 1833. An unclaimed body was sent to Guy's Hospital, by the Inspector of Anatomy, as a female. On removing the dress, however, it was found to be that of a male! From some suspicion respecting the cause of death, and the
habits of this person, a coroner’s inquest was held. It turned out that the deceased, whose age was 24, had assumed the dress of a female at the age of 14, and had performed in many parts of England as an actress. The features had a somewhat feminine character; the hair was very long, and parted in the centre; the beard had been plucked out, and the remains of this under the chin had been concealed by a peculiar style of dress. It was remarked during life that the voice was hoarse. The breasts were like those of a male, and the male sexual organs were perfectly developed. They had evidently been subjected to great traction, and appeared to have been drawn forward to the lower part of the abdomen. The state of the rectum left no doubt of the abominable practices to which this individual had been addicted. It was found that death had taken place from natural causes. The most remarkable circumstance in the case is, that the deceased had been attended in his last illness by an eminent physician (now deceased) for disease of the lungs; and so well was the imposition maintained, that his medical attendant did not entertain a suspicion of the real sex of his patient! (Med. and Phys. Jour., Feb. 1833, 168.)
IMPOTENCY. STERILITY.

CHAPTER LV.

IMPOTENCY.

Definition. — Impotency is defined, — An incapacity for sexual intercourse. It may depend—1st, upon physical; 2d, upon moral causes. With regard to the moral causes of impotency, they do not concern a medical jurist. Such causes are not recognised by law, and he has no duty to perform beyond the application of the principles of medicine to the purposes of the law.

Causes. — Impotency may depend on age, — on certain physical causes, e.g. disease, — or on congenital malformation or defect. With regard to physical causes, a division must be made between those which are remediable, and those which are not. The presence of disease of the testicle, such as atrophy or fungous tumours may give rise to incapacity; but the incapacity may be sometimes removed by an operation or by medical treatment, and therefore the physical cause may be removed: — in other words, it is remediable. To such cases as these the law does not extend; but it is always expected, in alleged incapacity, that the practitioner examined on the subject should be able to say whether there is or is not a prospect of cure. Upon this point his knowledge of his profession can alone assist him; no rules can be laid down for his guidance, for there may not be two cases that will precisely resemble each other in their features.
Hence it will be necessary to point out the chief causes of impotency which are of an irremediable nature, or those in which the incapacity is absolute and permanent;—a point upon which the law chiefly requires a medical opinion.

In strictness of language, the definition of impotency, as above given, may exist in a female as well as in a male; and undoubtedly a physical incapacity for sexual intercourse may exist in either sex. As an instance of this incapacity in the female, may be mentioned occlusion or obliteration of the vagina—a condition not necessarily indicative of sterility. The mere occlusion of the vagina may be a remediable form of the malady; but its entire obliteration would be absolute and irremediable. This latter condition, however, is the only instance of complete impotency in a female. Protrusion of the uterus or of the bladder into the vagina, is mentioned by some writers as cause of physical incapacity for intercourse; but these forms of disease may commonly be remedied by art, and therefore require no further notice.

In professional language, the term impotency is applied exclusively to defect in the male sex; and the term sterility is confined to all those conditions in the female which not only render intercourse impossible, but which render it unfruitful.

Procreative power in the male. Puberty.—Until the period of puberty, the testes remain small, and increase very little in size in proportion to other parts. Mr. Curling found that the size of the seminal tubes differed but little at the ages of eighteen months and eight years. The sexual function in the male depends entirely on the development of these organs; but the age at which it appears differs in different individuals. The age of puberty in a healthy male in this country varies from 14 to 17 years; its appearance is, however, affected by climate, constitution, and the moral circumstances under which the individual is placed. In some cases it is not fully developed until the age of 21.

The access of puberty in the male is indirectly connected with the subject of rape. A boy under the age of fourteen years is presumed in law to be incapable of committing a rape. (1 Hale 631, and Mathew's Digest, p. 87.) This presumption is probably based on the supposition that a boy at that age is impotent. The statute law, however, now merely requires proof of penetration, and rape therefore may be physically perpetrated by a boy at or even under fourteen years of age. In the case of Reg. v. King (York Winter Assizes, 1853), a boy aged 15 was convicted of rape on a girl under ten years of age. In a case elsewhere related (see Rape, post p. 701) a boy aged 19 communicated syphilis to a girl of six years of age. It appears that in India puberty shows itself much earlier in the male. Dr. Chevers, quoting from the Nizamut Adawlut Reports, states that a boy of 13 or 14 years of age was found guilty of rape and sentenced, in
consideration of his youth, to three years' imprisonment. A lad of 14 was convicted of rape on a girl of the same age; and in another case a boy only ten years old was convicted of rape on a girl three years of age! He was sentenced to a year's imprisonment. (Med. Jur. for India, p. 463.)

The seminal secretion in the male is not considered to be prolific until it contains those peculiar filiform bodies which are known under the name of spermatozoa or zoospersms. These are regarded by some physiologists as parasitic animals, but by others, with some probability, as freely moving cilia. (Recent Advances, Baly and Kirkes, 1848.) All agree that they are normal and essential constituents of the healthy and prolific seminal fluid. They are peculiar to the spermatic secretion, and, in healthy males, are always present in it after the age of puberty. They disappear in certain states of disease; and, when not found, it is a fair inference that the individual is impotent, or that he has lost the power of procreation.

The direct agency of the spermatozoon in fecundation has been most ably investigated by the late Mr. Newport. (Philos. Trans. 1853, vol. cxliii. part 2, p. 234.) I can here only briefly allude to his researches. His experiments were performed on the amphibia, by the aid of the microscope. It would appear from these (and his inferences are fairly applicable, within certain limits, to animals and man), that the presence of spermatozoon in the seminal secretion is indispensable to the impregnation of a female,—in fact, that the fecundating power resides in these living molecules. It is a curious fact, too, that active motion in the spermatozoon is essential to fecundation: thus, when these molecules are motionless or dead, ovum are not impregnated by them; and the power of impregnation is in proportion to the activity of this motion. The impotency arising from advanced age in the human subject is probably not so much owing to a deficiency of spermatozoon in the male secretion, as to their power of motion being exceedingly feeble. We learn further, that impregnation was more certain when the quantity of spermatozoon supplied to the ovum was not reduced to a minimum: hence, whatever may be the precise quantity of the spermatic secretion necessary to effect healthful impregnation, it is thus proved that a definite quantity of spermatozoon, or spermatic influence, is required to fecundate. Exhaustion from any cause, and probably from venereal excess or self-abuse, may lead to a loss of procreative power, by reducing the number and diminishing the active motive powers of the spermatozoon. How it is that fecundation is effected by this incorporation of the spermatozoon with the ovum, it is impossible to say; but the embryo is not the product of the development of the spermatozoon. The nature of the change is a mystery which appears to be placed beyond the power of human research. The existence of impotency in the
male, as well as of sterility in the female, and a want of pro-
creative power in the sexes when the individuals are otherwise
healthy, are to some extent explained by the results of Mr. New-
port’s researches. Without the penetration of the ovum there
is no fecundation, and the conditions and circumstances which
affect this result are very numerous.

In reference to the human ovum, there is an absence of that
immediate contact with the male fluid which occurs in the
amphibia. The human ovum may come into contact with the
spermatozoa at the ovary, in any part of the Fallopian tube, or
in the cavity of the uterus; but the spermatozoa may lose their
active motion before reaching the cavity of the uterus or the
tube; they may not be in sufficient number, or may not meet the
ovum under circumstances favourable to penetration. It is
probable that the ovum may maintain its vital power in the body
of the female for a considerable time after its extrusion; and
although the chances of impregnation may be thereby reduced,
yet fecundation may occur if all other circumstances be favour-
able. This would explain the occurrence of conception at any
time between two menstrual periods. (See ante, Date of
Conception, page 613.)

Impotency from age.—It may be fairly assumed that a male is
incapable of procreating until spermatozoa have appeared in
the seminal secretion. The age at which they appear varies with
all those causes which affect puberty. Mr. Curling informs me
that he found them in the secretion of a boy aged 18; but his
observations have not been specially directed to this question.
There is no doubt that in many cases they appear much earlier
than this. Sexual propensities are often strongly developed in
young children, and they may be prolific at a very early age.
Dr. Rüttel met with a case in which a female at the age of 14
became pregnant by a boy of the same age. (Henke, Zeitschrift
der S. A. 1844, 249.) This is the earliest age at which, so far as
I can ascertain, the procreative power has appeared in the male.
Dr. Hartshorne, American editor of this work, refers to a case of
extraordinary development of the male sexual organs in a child

In a case of contested legitimacy or affiliation, this question
regarding the age at which a procreative power may appear in
the male may have an important bearing. Thus the person may
be so young as to render it impossible that he should be the father
of a child imputed to him. Cases involving questions of legiti-
macy on this ground are not heard of in the present day; but in
ancient law-books there are decisions relative to the illegitimacy
of children born during marriage, because the alleged fathers
were seven, six, and even three years old! (Amos.)

The following case in reference to the affiliation of children
occurred in 1840:—A woman wished to affiliate a child on a
youth who was in his sixteenth year. The boy denied that he
was the father of the child; and there was reason to suspect that
the imputation had been wrongly thrown upon him in order to
divert suspicion from the real party. There was some difficulty
in this case; but it appears to me that the rule for a medical
man to follow on these occasions is this:—not to regard the
mere age of the youth, whether he be above or below the average
age of puberty, but to observe whether the sexual organs be fully
developed, and whether there be about him any of the ordinary
marks of virility, indicated by muscular development, the growth
of a beard, and a change in the voice. If these signs be present,
whatever may be his age, there is strong reason to suppose that
the sexual functions are developed. We occasionally hear of
instances of extraordinary precocity; but the development of
sexual power is generally accompanied by other well-marked
changes in the individual. Sometimes these changes do not make
their appearance until after the age of twenty-one.

On the other hand, it may be a question at what time the pro-
creative power disappears in a male. That impotency is one
of the natural consequences of advanced age is undoubted; but
this, as we know, forms no legal impediment to the marriage of
parties however old. The legal presumption is, that the generative
faculty does not disappear through age; and if this be alleged,
and legitimacy disputed on this ground, it must be satisfactorily
proved. This amounts almost to an impossibility; because it
is well known that there is no fixed age at which the sexual
functions cease either in the male or female; and individuals, at
least of the male sex, who had passed the ages of sixty, seventy,
and even eighty years, have been known to be capable of inter-
course and to be prolific. In relation to this question, it may be
mentioned as an interesting physiological fact, that Mr. Curling
found spermatozoa in the liquid taken from the testicles of a man
upwards of seventy years of age, and on one occasion in the
testicles of a person aged eighty-seven. Wagner states that they
are to be found in the secretions of men between seventy and
eighty years of age. Facts tend to render it highly probable that
the fecundating power may be retained by the male up to the
age of 100. According to Dr. Duplay, the seminal fluid of old
men contains spermatozoa, even when they are beyond the age
for fecundation (Med. Times and Gazette, June 4, 1853, p. 581);
but he does not state the circumstances which enabled him to
arrive at this conclusion. As far as experience goes, we must
infer that the presence of these bodies in the fluid implies the
existence of a fecundating power, and their absence, infecundity.
M. Duplay believes, from his anatomical observations on the
bodies of aged persons, that the causes of impotency in advanced
age are to be found rather in the excretory than in the secretory
apparatus. Thus he has met with obliterations in the canal of
the epididymis, the vas-deferens, and the vesicular, the effect of which is to prevent the accumulation and passage of the seminal fluid. (Med. Times and Gazette, June 28, 1856, p. 650.) Lord Erskine, in the Banbury peerage claim, quoted the case of Sir Stephen Fox, who was married at 77, and had four children, the last when he was 81. Dr. Schneider met with a case in which a man of 71 had a child by his wife, who was only 17. (Henke, 1842, ii. 165.) Dr. Rüttel mentions the case of a man, who, at the age of 92 years, married and had two children by his wife. When the procreative power even appears to be lost at an advanced age, the stimulus for intercourse is often very great. The same authority mentions cases in which these erotic feelings were remarked by him in reference to men between 75 and 86 years of age. (Henke, Zeitschrift, 1844, p. 252.) In all cases of protracted virility it is observed that the bodily and mental powers are also retained in an extraordinary degree, showing the close relation which exists between sexual function and corporeal development, even to the latest period of life.

The English law on this subject was clearly laid down in the Banbury Peerage case, brought before the House of Lords in 1806. Lord and Lady Banbury had been married twenty-one years without having had issue, when his lordship died at the age of 85 years. The peerage was claimed by the descendants of an individual who called himself the son of Lord Banbury; but in fact it was alleged that he was the son of Lady Banbury by an adulterer, during her husband’s life. According to the evidence, Lord Banbury did not appear to have been aware of his existence; and the child had always been known by another name. (Amos, Med. Gaz. vii. 741.) One of the grounds upon which the legitimacy of the descent of the claimant was contested was, that the deceased nobleman had become impotent through age; but it was argued by Sir S. Romilly, that the law placed no limit on the powers and faculties of men. The assumed impotency of the alleged parent on the ground of age, could never be admitted as a proof of the illegitimacy of the supposed offspring. In 1813 the House decided against the claim, but not on the ground of impotency from age in the husband. It was proved that Lord Banbury was hale and hearty at the time of his death; but the moral circumstances of the case, especially the concealment of the birth of the child from the husband, were considered to be sufficient to prove that the child through whom the claim was made was not the offspring of Lord Banbury. This case incontestably proves that there may be capacity of intercourse, and possibility of access on the part of a husband, yet every species of moral evidence will be admitted to rebut the legal presumption of legitimacy when there are reasonable grounds for disputing it. Sir S. Romilly remarked, in reference to the retention of procreative power in advanced age, that the liberality of the English law on
IMPOTENCY FROM DISEASE OR ACCIDENT.

this subject was excessive, for there was no age, from seven upwards, at which a man had been denied the power of procreating children! (See, in reference to this subject, Henke, Zeitschrift der S. A. 1842, ii. 162, 320.) Males of the age of 14 and females of the age of 12, are legally competent to contract marriage.

Impotency from local disease or accident.—The loss or destruction of the penis or testicles, either by disease, accident, or from necessary operations, would be sufficient to render an individual irretrievably impotent. The loss of one or both testicles from any of these causes would be indicated by the presence of distinct cicatrices in the scrotum. When both have been removed by operation, the individual is incurably impotent; but if the organs be healthy, a sufficiency of the spermatic fluid to confer procreative powers may remain in the ducts for two or three weeks after the operation. The loss of one testicle only does not render a man impotent. *Monorchides*, as they are called, have been known to be prolific. Cases of this kind must not be confounded with those in which one or both testicles have not descended into the scrotum. In some rare instances, the organs do not descend into the scrotum at the usual period; but one or both may remain in the abdomen, or in the inguinal canals, and only descend some time after birth; or one may be found in the scrotum, and the other remain during life in the abdomen. In these cases the organs have been mistaken for, and treated as, ruptures by the application of a truss! (Henke, Zeitschrift der S. A. 1844, i. 249. Curling on Diseases of the Testis, 2nd ed. p. 31.) When one of the organs only has descended, there is no ground, ceteris paribus, to impute impotency. When neither has descended, the scrotum will be found empty, without any cicatrix, but all the other marks of virility may still be present. These individuals have been called *Cryptorchides*. It has been said that in all such cases the testicles are to be regarded as congenitally absent or defective; but this is an error. Dissection has clearly proved that they have merely not descended; and although remaining in the abdomen, there is no reason to believe that they are incapable of performing their functions. On this contested question Mr. Curling justly observes, "We must not infer that the testicle is defective in consequence of its detention in the abdomen; but we have grounds for presuming that an original imperfection is the primary cause of its remaining in that situation. The knowledge that such an imperfection sometimes exists, however rarely, must always induce us to regard the infirmity, when existing on both sides, with anxiety, which, while the patient is young, we have no means of removing. At the adult period, the external characters of the body distinguishing the sex, habits, disposition, and desires of the individual, will enable the surgeon to arrive at a correct conclusion as to the efficiency
of the retained organs, and to decide on the propriety of marriage." (Diseases of the Testis, 2nd ed. p. 28.) According to this gentleman, a testicle situated in the abdomen is in a more satisfactory position, and is much less exposed to injury and disease, than one which has been arrested in the groin. An examination of several cases shows that so long as the organ is in the abdomen, although small, it is healthy, and the ducts and secreting structure have been found perfect. In those instances in which the testicle has been detained in the inguinal canal, it has been found more or less altered by disease, and the ducts obliterated; in such cases its functions are destroyed.

The absence of the testicles from the scrotum is a state very rarely seen. Mr. Marshall met with only one case of non-descent of one testicle in 1000 recruits, and with one case of non-descent of both testicles in 10,000 recruits. There are three preparations, showing the non-descent of the testes, in the museum of Guy's Hospital; one of them was taken from a gentleman who shot himself from despondency at his supposed defective condition. Hunter thought that the undescended testicles were imperfect both in their organisation and functions, and that cryptorchids were invariably impotent. But the recent researches of Mr. Curling and others have shown that there is no foundation for this opinion. Mr. Cock informs me that he has taken notes of the cases of two men whose testicles had not descended, and in whom the virile functions were perfect. One of them, before he had reached the age of thirty years, had already married twice, and had had children by each wife, besides illegitimate children which were affiliated on him during the time he lived in service! In general it will be found that the usual signs of virility have appeared about the person. With such well-ascertained facts as these, it is unfortunate that MM. Goubaux and Fallin have reopened the question by asserting, from their experiments, that when the testicles are retained within the abdomen the microscope fails to detect spermatozoa in the seminal fluid, and the persons or animals are impotent. (Lancet, Oct. 11, 1856, p. 410.) No better evidence can be desired than that such persons have actually been known to procreate children!

If, in a case of non-descent, there should be a non-development of the other external organs, and this is accompanied by a total want of the characters of virility, no doubt can be entertained that the individual is irremediably impotent. The testicles may, in such a case, be really congenitally absent—a fact only ascertainable by an examination after death. I quite agree with the opinion expressed by Mr. Curling, which is confirmed by the facts above mentioned, that the detentin of the testicles in the abdomen is perfectly compatible with virility; and in cases in which there are no external marks of effeminacy, or other grounds for suspecting impotency, and the patient is subject to erections, the
imperfection does not offer any bar to marriage, nor is it a justifiable ground for divorce.

The presence of what have been called supernumerary testicles does not affect the virile powers of the individual. These have in general been found, by dissection, to be tumours connected with the healthy glands, and not at all adding to or interfering with their functions. Even the presence of two or three penes, according to Mende, is no bar to the exercise of sexual power, provided only one possesses the normal characters of the male organ. This author refers to cases of duplex organs. (Ausführl. Handb. d. ger. Med. iv. 337.)

In some instances there is an arrest of development in the external organs: and with this there is generally an absence of sexual desire. Mr. Farr met with a case in a man aged forty-two, in whom the sexual organs remained undeveloped and in an infantile state. There was some difficulty in finding the testicles, in consequence of their small size. On examining the contents of the gland microscopically, no spermatozoa were found. This person's voice was effeminate, and he was devoid of hair on the chin and pubes. (Med. Gaz. xli. 857.) It is not, however, always to be inferred that an individual with undeveloped organs is incurably impotent. The following case is quoted by Mr. Curling:—A gentleman, aged twenty-six, consulted Mr. Wilson on the propriety of his marrying. His penis and testicles very little exceeded in size those of a youth eight years of age, and he had never, until this acquaintance with his intended wife, felt the desire of sexual intercourse. He married, and became the father of a family; and at the age of twenty-eight the organs had attained the full development of the adult. (Op. cit. 95.) Under wasting of the testicle, or when the gland is extensively diseased, and the sexual desire disappears, there can be no doubt of impotency. The functions of these organs are not, however, very readily impaired by local disease. The spermatic secretion is still properly formed, even when only a small part of the gland remains healthy,—a fact proved by a microscopical examination. Certain diseases of the appendages of the testes may, however, render a person impotent. The spermatic secretion is commonly suspended in most severe diseases which affect the body.

A very frequent cause of impotency in the adult, when the organs are apparently sound, is spermorrhcea, arising from abuse. This, however, is remediable to a greater or less extent by treatment. (See Curling, Diseases of the Testes, 2nd ed. p. 386; also Med. Times and Gazette, Jan. 23, 1858, p. 95.)

On the absence of the penis, as well as on its defective organization, as causes of impotency, some remarks have been already made in the preceding section. Sometimes the defect is merely connected with the urethra. Thus the orifice may be on the dorsum penis, and in other cases underneath the organ, so that
the urethra may terminate at a variable distance from the glans penis. Those labouring under the former defect are said to have *epispadia*; and under the latter, *hypospadia*. The power to have fruitful intercourse will in either case depend on the situation of the urethral aperture. Rüttel knew an instance of an hypospadiant having several children. (Henke, Zeitschrift, 1844, p. 258.) Some doubt has existed respecting the virile powers of those who are affected with hypospadia. In September 1850, a lad, aged seventeen, was summoned before the magistrates of Kidderminster on a charge of affiliation, in reference to the pregnancy of a girl aged eighteen. The defence was, that he could not be the father of a child, because there was such a malformation of the penis as to prevent prolific intercourse. On examination, the urethra was found to terminate on the under surface of the penis, about an inch and a half from the glans, by a small elliptical orifice, which allowed the urine to pass, but with some difficulty. One medical witness gave it as his opinion, that it was not impossible, but highly improbable, that the defendant should possess procreative power; another freely admitted the boy's capacity, and the case was decided against him. (Med. Times, Sept. 21, 1850, p. 321.) There can be no doubt that this was a correct decision. When the urine can pass, the seminal fluid can pass, and the only question is, whether the intromission can be such as that the misplaced orifice should come in contact with any part of the vagina. This must depend on the situation of the orifice. [Cases illustrative of the fully prolific powers of hypospadians will be found in the Med. Times, Sept. 14, 1850, p. 292; and Oct. 12, 1850, p. 392. An instance of the virility of a hypospadian has been published by Mr. Noble, of Manchester, in the Assoc. Med. Jour. March 18, 1853, p. 236.] Similar remarks apply to epispadians. These malformations are sometimes remediable: but whether remediable or not, they are not, under any circumstances, to be regarded as absolute causes of impotency.

The incapacity for intercourse in either sex may arise from *extensive disease* affecting parts in and around the organs of generation. The medical opinion here must be regulated entirely by the circumstances attending each case.

*Impotency from general disease.*—In the preceding paragraphs the influence of local disease in affecting virility has been considered. But there is a class of cases which may come before a practitioner, in which, with well-formed organs in the male, there will be a state of impotency. Sometimes this may depend on natural weakness of constitution, or on a want of proper development of the muscular and nervous systems: at other times it is due to certain diseases, and it is then of a temporary nature, persisting while the body is still suffering from the disease, and disappearing on recovery. As a converse fact, there are certain *diseases* which appear to bring out the dormant virile powers of
persons, or to excite to a higher degree of intensity those which already exist. Thus it is said that in convalescence from fever, there is occasionally extraordinary salaciousness: but this statement requires confirmation. Again, there are some diseases which neither interrupt nor affect the exercise of the sexual functions.

As a general rule, diseases which do not affect the brain and spinal marrow, and which are not attended with great debility do not prevent fruitful intercourse. On the other hand, diseases which are attended or followed by great debility, suspend or destroy sexual power. Among these diseases may be mentioned — water in the chest, general dropsy, especially if attended with effusion in the sexual organs, — nervous and malignant fevers which affect the brain, — apoplexy, palsy, and other diseases which directly attack the brain or spinal marrow. These last-mentioned diseases probably act by suspending the secretion or altering the nature of the prolife fluid, as well as by preventing that erection of the male organ, without which intercourse cannot take place. The sexual function is so intimately allied to bodily vigour and nervous energy, that the integrity of the one may be pronounced to be essential to the integrity of the other. Habits of drunkenness and the abuse of alcoholic liquids may give rise to impotency by the injury done to the brain and nervous system. (The reader will find this subject fully discussed by Mende, Ausführung. Handb. der ger. Med. iv. 349.)

In the case of Legge v. Edmonds, which came before the Vice-Chancellor (1854-5), a question arose respecting the legitimacy of a child conceived during wedlock, but born four months after the death of the husband. In presumption of law the child was legitimate, because husband and wife were living together, and conception and birth were, as to date, in accordance with the ordinary rules. Two months preceding the assumed date of conception, the husband, who was stated to have been of intemperate habits and addicted to the abuse of alcoholic liquids, was seized with paralysis (hemiplegia), accompanied by coma, and he lost the use of the right side of his body. In about a month he partially recovered from this, but the paralysis never left him, and his strength was greatly reduced by strong depletory treatment. A month after the assumed date of conception another attack followed, — his constitution was shattered and broken up, — general dropsy and disease of the liver followed, and he died five months after the supposed date of conception, and four months previously to the birth of the child. It was alleged that the wife had been in habits of adulterous intercourse during the period of her husband’s illness, and that the adulterer was the father of the posthumous child. A year after the death of the husband, the widow married the alleged adulterer (the defendant), and had by him four children. For
eight years preceding the death of the husband, the woman had borne no child, and it was only when the intimacy with the alleged adulterer commenced, that she became pregnant. The question submitted to Dr. Carpenter and myself on this case was — Was it possible or probable that the husband could have begotten the child in the diseased condition in which he was represented to have been? The opinion given was that it was possible, because there was opportunity of access; and sexual power, if lost by the attack of paralysis, might have returned at the time corresponding to the date of conception; but, on the other hand, it was pronounced to be in the highest degree improbable. It was alleged that diseases of this kind tended to suspend sexual power,—that in this particular instance, the effect would be aggravated by the known intemperate habits of the husband, and the severe depletory treatment which he had undergone adding to general exhaustion and debility of system. Further, the non-procreation of children during the last eight years of the marriage was clearly not owing to sterility or incapacity in the wife, because she had borne four children by the adulterer. It could therefore, in our opinion, be assigned only to impotency in the husband, probably arising from his intemperate habits. The general conclusion which we drew from the facts laid before us, was that the husband at the time was impotent and incapable of begetting a child. Evidence to this effect was given by us in the inquiry subsequently directed by the Vice-Chancellor. At the same time we did not feel justified in asserting that intercourse on the part of the husband was actually impossible. Dr. Guy and Dr. Semple gave evidence on the part of the defendants to the effect that there was no proof of impotency in the husband, and that a man labouring under such an illness as that from which he was stated to have suffered would still be physically capable of procreating children. The evidence regarding the precise bodily condition of the husband about the date of conception was very conflicting; and on this ground probably, as well as in conformity with the legal rule that a child begotten in wedlock is to be regarded as the child of the husband — unless an impossibility of access or intercourse is proved, — the Vice-Chancellor decided in favour of the defendants, — that the child was the child of the husband, and was entitled to the estate which the plaintiffs, the heirs of the husband, sought to recover from the defendant and the widow who had married him. There was no evidence from parental likeness, for the child through whom the claim arose, had died some time before proceedings were taken.

Without disputing the equity of this decision, it involves this assumption, that, during eight years of a somewhat dissipated life, and before being attacked by paralysis (hemiplegia), the husband did not possess procreative power, and that this only
manifested itself (suddenly) after a severe attack of the disease, from which he had not (entirely) recovered. Such an assumption is, I believe, contrary to all experience with regard to the influence of the nervous system on the generative functions.

Mr. Curling observes that diseases and injuries of the spinal cord producing paraplegia have no direct effect on the testicles, but destroy the power to copulate (Op. cit. p. 371). When there is a wasting of the testicles as a result of general paralysis of long standing, there can be no doubt of impotency; but Mr. Curling quotes a case from a foreign writer, in which under paralysis (paraplegia) of some years' duration, a man retained sufficient sexual power to have prolific intercourse. When the paralytic person is advanced in age, it is highly probable that he is impotent. In December 1857, a case was referred to me in a question of bastardy for my opinion on the capacity for intercourse under the following circumstances. A woman required an order of affiliation on the putative father of her bastard child. She was a widow, and the illicit connexions took place about two months before her husband's death. The husband was eighty-four years of age, was bedridden, and for many weeks before his death could not move in his bed, and was unable to pass his urine without assistance. The medical opinion of those who examined him was that he was impotent from physical infirmity, and in this opinion I concurred, stating, however, that unless the male organs were diseased or destroyed, it could not be said that intercourse was impossible. It was, however, wholly improbable that the husband should have been the father of the child.

Some diseases appear to have a specific influence on the development of the sexual organs; and although not influencing the nervous system—not affecting the sexual organs directly, nor leaving any trace of constitutional disturbance—they lead to an arrest of sexual development, and therefore to impotency and sterility. One disease has been especially noticed as possessing this influence, namely, *Cynanche parotideae*, or mumps. Sir Astley Cooper was accustomed to state in his lectures, that on the subsidence of this disease, when it attacked adolescent males and females, the testicles in the male and the breasts in the female became occasionally inflamed. The organs shrank and slowly withered. Their development was arrested, and in the male incurable impotency was the result. Dr. Krügelstein refers to a case in which a strong and healthy man was rendered incurably impotent after an attack of this disease. (Henke, Zeitschrift, 1842, ii. 354. See also Curling, Op. cit. p. 59.)

Blows on the head or spine, by affecting the brain and spinal marrow, may produce impotency. Several cases of impotency from this cause are related by Curling (Op. cit. p. 362). It has been noticed that blows on the under and back part of the head, in the region of the cerebellum, have been followed by loss of

---

*XX3*
sexual power on recovery. Sometimes this is temporary; but at other times when there is wasting of the testicles it is permanent and irremediable.

Of moral causes it is unnecessary to speak. The sexual desire, like other animal passions, is subject to great variation; and there are instances on record, in which men, otherwise healthy-looking and healthily formed, have experienced no desires of this kind. They are in a state of natural impotence: a condition which the Canon law designates as frigidity of constitution. This is not to be discovered by examination, but rather from their own admission. Under this head we may class hypochondriacal affections. [For a valuable scientific summary of the causes and treatment of impotency I must refer the reader to the work of Mr. Curling, Diseases of the Testis, 2nd ed. p. 359, 1856.]

STERILITY.

**Definition.** — Sterility is usually defined to be “the inability to procreate, or a want of aptitude for impregnation.” It is not usual to speak of sterility in the male, although there may be procreative incapacity; because the defective condition in this sex is fully expressed by the word impotency. In the strictness of language, a male who has been castrated is sterile; but it is sufficient to say that he is impotent. It is possible that many apparently healthy and well-formed males may be sterile without being impotent, i.e. that they may have intercourse without procreating; — for the power to copulate must not be confounded with that of procreation: but it is more probable that the defect in such cases rests with the female, and not with the male. Sterility should, therefore, imply that condition of a female in which there is an “inability to conceive.” This appears to be the true meaning of the term, and the sense in which it is used, not only by the best writers, but in common phraseology.

**Procreative power in the female.** Puberty. — In the female, the procreative power is supposed not to exist until after the commencement of menstruation, and to cease upon the cessation of this periodical secretion. The menstrual function is commonly established in females in this climate between the ages of fourteen and sixteen; but it may occur much earlier: indeed, in some rare instances, a discharge resembling the menstrual has been known to occur in mere infants. In other cases its appearance has been protracted to a much later period. According to Dr. Rüttel, the menstrual function appears in the smallest number of females at 12, 13, and 14 years, and in the largest number at 16, 17, and 18. In many it is only first established at from 19 to 21 years; and he states that at this age he has often found the uterus very small, and quite undeveloped. Perhaps, in this country, the most frequent age for the commencement of men-
sterilization may be taken at 15 years. It is liable to be accelerated in its appearance by certain moral and physical conditions under which a female may be placed. According to Dr. Chevers, females in India begin to menstruate after the twelfth year or at the beginning of the thirteenth, and the function continues until the fortieth or even the forty-fifth year. Menstruation at ten years is very uncommon, and probably does not occur in more than one or two instances out of a hundred females. It is equally rare that it should be delayed beyond the thirteenth year. (Medical Jurisprudence for India, 1856, p. 461.) The most common intervals for the appearance of this function are twenty-eight and twenty-one days. It is sometimes late in life before it appears. Dr. Camp's found that it had not appeared in a married woman, att. 30, who had borne no children. (Med. Gaz. xxxix. 409.) Another case is mentioned in the same volume where it appeared for the first time at the age of 47 (p. 567). So soon as this function commences, the female may be considered to have acquired procreative power; but a female may conceive before the function has commenced, during the time of its occurrence, or after it has ceased. From facts elsewhere stated (ante, p. 350) there is reason to believe that the period which immediately precedes or follows the discharge is favourable to conception: although the experience of most accoucheurs has proved that impregnation may take place at any period between one menstruation and another.

It is important to remember that these changes in the uterus may produce remarkable effects by sympathy with the brain and nervous system. At or about the time of puberty, especially if any cause of obstruction exist, females become irritable, easily excited, and they have been known to perpetrate, without motive, crimes of great enormity, such as murder and arson. A propensity to steal is also stated sometimes to manifest itself. (See post, Kleptomania.) It has been remarked that acts of arson have been frequently committed by girls at this period of life, and the crime has spread by imitation. The case of Brixey, tried for the murder of an infant, and acquitted on the ground of insanity, will serve as an illustration of the morbid effect produced on the brain by disordered menstruation. (See post, Insanity.) The state of the mind should be therefore carefully watched at this period of life: and any causes of violent excitement removed. Irregularity, difficulty, or suppression of the menstrual secretion may give rise to temporary insanity. Puberty in the male may be attended with similar morbid propensities: but these are not so commonly witnessed as in the female sex.

Pregnancy before menstruation. — The occurrence of menstruation is not indispensable to pregnancy. Many cases are on record in which women who had never menstruated have conceived and borne children. One case is reported, in which a female, aged
25, became pregnant and bore a child, and menstruation was only regularly established afterwards. (Lancet, Feb. 1842.) Dr. Murphy mentions another case of pregnancy previous to menstruation, in a woman aged 23. (Obstetric Reports, 1844, p. 7.) Numerous cases of conception without previous menstruation are quoted by Capuron (Méd. Lég. des Acc. 96); and no fewer than nine instances of pregnancy before menstruation have been collected by Mr. Whitehead. The females were all in excellent health during the whole time, and one did not menstruate until more than two years after the marriage had been consummated. (On Abortion, 223; see also Orléa, Méd. Lég. 1848, i. 257.) Another case will be found reported in the Medical Gazette (vol. xlvii. p. 969). Dr. W. Taylor met with a case in which a female aged 13 bore a child before menstruation had appeared. (Med. Times and Gazette, March 12, 1853, p. 277; see also, for remarks on this subject, Ed. Monthly Jour., July 1850, p. 73.) The late Dr. Reid states that a patient of his bore a child at the age of seventeen, without having previously menstruated; and he has collected a number of cases, from various authorities, of pregnancy occurring in females who had not menstruated. (Lancet, Sept. 3, 1853, p. 206.)

According to Bischoff, the uterine discharge of blood in menstruation is only a symptomatic, although usually a constant, appearance. But it may be absent, while the ovarian changes go on in the usual way: hence a non-menstruating woman may conceive. At the menstrual period the uterus undergoes certain changes; the mucous membrane is swollen, and the uterine glands are strongly developed: hence the expelled ovum finds a ready spot of attachment when impregnated; and an absence of this swollen condition of the mucous membrane at other times may be one cause of sterility. From an inspection of the generative organs in the human female, in thirteen cases, during or shortly after menstruation, he infers that the change in the uterine mucous membrane is synchronous with the commencement of menstruation, and it has been observed to remain for so long a period as eighteen days after this function had ceased. The true function of menstruation appears to be the ripening and separation of the ovum. (Med. Times and Gazette, April 8, 1854, p. 354.)

Instances of premature puberty in the female are now very numerous: they are far more common than in the male sex. Mr. Whitmore met with the case of a female child who, from a few days after birth, menstruated regularly at periods of three weeks and two or three days, until she had attained the age of four years, when she died. On inspection after death, she appeared like a much older girl. The breasts were unusually large, and the female organs and lower limbs were considerably developed. (North. Jour. Med., July 1845, p. 70.) Another
CASES OF EARLY PREGNANCY.

681

case is reported in the Lancet (Jan. 29, 1848, p. 157). This was a child aged three years. The breasts were as healthily developed as in an adult of twenty years; and the female organs were also as much developed as in a girl at the age of puberty. It was found that this child, who had been regularly menstruating for twelve months, had the appearance of a little old woman. (For other cases of menstruation at five years, see Med. Gaz. xcv. 548; and at three years, vol. xlvi. p. 244.) In these instances there is great reason to believe that the procreative powers are early developed; but it is not common to hear of such young females becoming impregnated. A case is mentioned by Dr. Beck, in which a female menstruated at one year; she became pregnant, and was delivered of a child when little more than ten years old. Dr. Walker met with a case in which the menstrual function was established at the age of eleven and a half years, and the patient was delivered of a living child when only twelve years and eight months old. (Amer. Jour. Med. Sci., Oct. 1846, p. 547.) In another, observed by Rütel already referred to, a female of the age of fourteen became pregnant by a boy of the same age. He also quotes three others, where one girl of the age of nine, and two of the age of thirteen, became pregnant (loc. cit.). The first of these three cases represents the earliest age for pregnancy yet assigned by any author.

I am indebted to Sir Eardley Wilmot, for the particulars of a case (Reg. v. Chattaway) which was the subject of a trial on the Midland Circuit. At the Coventry Summer Assizes, 1848, he conducted a prosecution against a man, at 45, for a misdemeanor in having had carnal knowledge of a girl named Sprason between the ages of ten and twelve years. When intercourse was first had, the girl was eleven years and eight months old; it was repeated several times subsequently; and when the prosecutrix gave her evidence in Court, it appeared from the statement of the mother that the child was in the last month of her pregnancy; she was then not quite twelve years and six months old. Sir E. Wilmot ascertained by inquiry that menstruation had commenced in this girl at the age of ten years and two months, and had continued regularly up to December 1847, which was about the time when she first had intercourse with the prisoner. It appeared that she was a factory girl; and to the heat, confinement, and association with males, to which girls are subjected in this employment, may be referred the early commencement of puberty. When menstruation has thus commenced, conception may always be the result of sexual intercourse. The prisoner was convicted, and sentenced to two years' imprisonment with hard labour. The reader will find some additional particulars in reference to this case, by Mr. Smith, of Coventry (Med. Gaz. vol. xlvi. page 751).

Age at which menstruation ceases. Menstrual climacteric.—The
average period at which this function ceases in the female is usually at the age of from forty to fifty years: but as it may commence very early, so it may continue very late in life. In one case it has been known to cease at the age of 23; and in another instance it has continued to the age of 66 and even of 75 years. (Whitehead, op. cit. 145, et seq.) Mr. Thomas met with a case in which a woman had ceased to menstruate at the age of 45, but the discharge suddenly reappeared after an attack of illness when she had reached the age of 69. The discharge appeared several times, but not with monthly periodicity. It seems that her mother and sister had also menstruated at the ages of 69 and 60. (Med. Times and Gazette, Aug. 7, 1859, p. 148.) In a case which occurred to Capuron, it continued beyond 60 (op. cit. p. 98); but a more remarkable case, both of late menstruation and late pregnancy is quoted by Orfila from Bernstein. A female in whom the function appeared at 20, menstruated until her 99th year. Her first child was born when she was 47, and her seventh and last, when she was 60. (Méd. Lég. 4ème ét. 1848, i. 257; see also Briand, Man. Complet de Méd. Lég. 1846, 137.) From these facts, it is clear that it is impossible to fix the age of a female by the period at which this "change of life" occurs. At the best, it can only be the average of a certain number of instances. This question arose in the case of Clark v. Tutom (Kingston Lent Assizes, 1848), in reference to the identity of a female, through whom property was claimed by the husband, who was the plaintiff in the action. The marriage had taken place in 1794; the parties separated in 1809; and the plaintiff's wife, as it was alleged, died in 1843, when, by direction of the defendant, the age of 55 was put upon the lid of her coffin. A medical gentleman who attended her in 1841, deposed that from being then in her menstrual climacteric, he should consider her not to have been more than 50 at that time. He stated that the general period for the cessation of menstruation was 44; it was rarely protracted to the age of 50. On this assumption, it was impossible that the deceased could have been the plaintiff's wife, because at the time of the alleged marriage she would have been only three years old. On the part of the plaintiff, direct evidence was given to show that the deceased was his wife; and it therefore remains to be considered whether the adverse medical opinion is or is not consistent with medical experience. It is obvious from the cases above quoted, that menstruation may continue to 66 or 70 years of age, and that this may have been an exceptional instance. The plaintiff had a clear right to this medical presumption in his favour; and admitting that his wife was 17 at her marriage, she would have been menstruating in her 66th year. Hence it is evident, that the medical facts of the case were compatible with the evidence adduced on the part of the plaintiff. At the trial, those well-
known exceptional cases of menstruation beyond the 50th year were not even referred to; nevertheless the jury returned a verdict in favour of the plaintiff.

Is it possible for a female to become pregnant after menstruation has ceased?—It is commonly asserted and believed that, after the cessation of menstruation, a woman is sterile. This is doubtless the general rule; but in a medico-legal view it is necessary to take notice of the exceptions. Mr. Pearson, of Staleybridge, communicated to the Lancet, some years ago, the case of a lady, aged 44, who, up to September 1836, had given birth to nine children. After this, the menses appeared only slightly at the regular periods until July 1838, when they entirely ceased. Owing to this, she supposed that she was not liable to become pregnant; but, on the 31st December 1839, therefore eighteen months after the entire cessation of the menses, she was delivered of her tenth child. Hence conception must have taken place at from eight to nine months after the final cessation of the discharge.

Latest age for pregnancy.—The age at which women cease to bear children is usually from forty to fifty years; but as they may menstruate, so they may conceive, beyond the last of these periods. Besides, the facts above mentioned show that the continuance of menstruation is not absolutely necessary for conception. Numerous instances are on record of females advanced in life bearing children. A case is reported in which a well-formed female, who had been married nineteen years did not bear a child until she had reached the age of fifty. (Schmidt's Jahrbücher d. Med. 1838, S. 65; Henke, Zeitschrift, 1844, S. 251.) In this case it is stated that menstruation had ceased two years before conception. Rüttel observed in twelve women that they bore their last children at ages varying from forty-five to fifty. Ottinger met with an instance of a female bearing a child at fifty; Cederschjald with another, where the woman was fifty-three, and menstruation still continued. Haller records two cases in which women at sixty-three and seventy respectively bore children. (Briand, Man. Complet de Méd. Lég. 137.) Nevermann has drawn up a table in reference to the late ages of life in which women have borne children. Out of 1000 cases in 10,000 births, he found that 436 children were borne by females at the ages respectively—

A case has been communicated to the Med. Gaz. (xxxix. 250) by Dr. Davies, of Hertford, in which a woman was fifty-five when her last child was born. She menstruated up to that time.

We cannot pretend to fix the age at which pregnancy ceases to be possible, and beyond which it cannot occur. Questions of this kind have a very important bearing on the subject of legitimacy; and unless the law looks to something more than ordinary experience in such matters, the decisions of Courts must be inequitable. The legitimacy of the claimant of the Douglas Peerage, about the middle of the last century (ante, page 543), was contested among other grounds, on the presumed loss of procreative power in the female said to be the mother, who was in the fiftieth year of her age at the time of the alleged birth, and who therefore must have conceived when in her forty-ninth year. Lords Camden and Mansfield justly decided that this was no objection to the legitimacy of the appellant. The fallacy of trusting to a ground of this kind as evidence of illegitimacy is proved by a reference to the numerous cases already quoted. One somewhat similar to that of the Douglas Peerage occurred in France in 1754. François Fojat claimed an estate as heir to his mother. His claim was resisted on the ground that, according to the baptismal registry, his mother could not have been the legitimate heiress of the party through whom the claim accrued; because her alleged mother would then have been in her fifty-eighth year; and this, it was alleged, was beyond the age of child-bearing. Ancient records were searched, and the claim of legitimacy was admitted, because menstruation and conception had been known to occur at periods of life even later this. (Capuron, Méd Lég. des Accouch. 93.) This author quotes a case in which a healthy woman menstruated until she had passed her sixtieth year, and her last child was born when she was sixty years of age. (93.) Other cases of births at the age of sixty-three and sixty-five are referred to; but these appear to be of a less authentic kind. The truth is, in giving a decision, the law is bound to look to the anomalies connected with the exercise of the generative function; and therefore the limited experience of a few witnesses, casually taken, can hardly be expected to supply satisfactory answers to questions of this kind. It establishes no presumptions respecting the presence or absence of this power at any period of life; and it therefore leaves each case to rest upon the whole of the circumstances which attend it.

Causes of sterility.—The causes of sterility in the female system are very numerous. Some of them depend upon peculiarities of constitution, the sexual organs being well formed and developed,—others upon latent changes or congenital defects in the uterus and its appendages, only discoverable by an examination after death. Sterility rarely becomes a medical question in contested cases of legitimacy; for a claim on the part of an individual to
be the offspring of a particular woman, unless the female were in collusion with the claimant, could only be made after her death; and if not disproved by medical evidence, showing that the woman could not have borne children, it would in general be easily set aside by circumstances. If the uterus, ovaries, or other parts were congenitally defective or absent, or if there were external sexual malformation, accompanied by occlusion or obliteration of the vagina, a medical witness could have no difficulty in saying that a woman must have been sterile. (See Med. Times and Gazette, Jan. 23, 1858, p. 96.) A mere occlusion of the vagina, removable by operation, does not necessarily indicate sterility, for the internal parts may be healthy and sound. In some instances, the ovaries or the uterus may be entirely absent, or the Fallopian tubes may be obliterated,—facts which cannot in all cases be determined during life; in other instances, these organs may exist, but be defectively developed. Dr. Coley relates a case in which, in a female, at 26, it was found after death that the uterus was not larger than in an infant of one or two years of age. The mouth and neck of the uterus were not larger than a crow-quill in diameter, but perfectly defined: one of the ovaries was imperfect. The patient had, on a few occasions, observed an appearance resembling menstruation. (Obstet. Rec., May 1848, 169.) The absence of a uterus, and the absence of the function of menstruation, do not necessarily prevent the development of strong sexual propensities, although there is of course incurable sterility. (See case in Assoc. Med. Jour., July 29, 1853, p. 672.)

Some of the physical causes of sterility in the female are removable by art. Thus, when the vagina is unnaturally closed, this condition may be often remedied by operation. An instance of this kind is related by Mr. Dumville (Medical Gazette, xl. 1116), in which a female subsequently married and bore a child. It is a fact worthy of notice, that if the internal organs be in their normal condition, the slightest aperture will suffice for impregnation. Penetration is not necessary. Women have thus been known to conceive under circumstances which appeared quite adverse to the possibility of conception; and when they had arrived at the full time, it has been found necessary to make a free incision into the parts which resisted the passage of the child’s head. A remarkable case of this kind, which occurred to Dr. Simmons, is quoted in the Lancet (June 19, 1847, p. 651), and there are many others of a similar nature on record. Sometimes the external passage is free, but the occlusion may be at the os uteri. This is a cause of sterility which, however, admits of remedy by operation. A case of this kind was successfully treated by my colleague Dr. Oldham (Med. Gaz. xxxviii. 919).

An absence of the menstrual function (amenorrhoea) has been described as a cause of sterility; but several cases have been
already mentioned, which show that females who have never menstruated, or in whom the discharge has appeared and has ceased for many years, and who are otherwise healthy and well formed, may become impregnated. When, however, the absence of menstruation depends on occlusion of the mouth of the uterus, or other physical causes of the like nature, there will of course be sterility. If, in other respects, the female be well formed, she cannot be regarded as in a necessarily incurable condition. Dr. Oldham has published two cases in which the females had each attained the age of forty-eight years without having menstruated. (Med. Times and Gaz., March 27, 1852, p. 311.) There was general good health, with a proper development of the sexual organs, in both. An inordinate periodical discharge (menorrhagia), depending on uterine disease, or disturbed and difficult menstruation (dysmenorrhoea) is a frequent cause of sterility. The deranged health which accompanies these morbid conditions may be, however, itself unfavourable to conception. Difficult menstruation frequently depends on stricture of the neck of the uterus. Sterility arising from this and other diseased states of the menstrual function admits of remedial treatment. Mr. Brown has also noticed that prolapsus ani, fissure of the rectum, and other diseases affecting this bowel, as well as the presence of worms therein, may cause temporary sterility. (Med. Times and Gaz., Feb. 21, 1857, p. 186.)

There is a popular notion that women during menstruation and lactation are sterile; but this is incorrect. (Henke, Zeitschrift, 1844, 263.) Leucorrhoea, or that morbid state of the uterus and vagina which accompanies it, is commonly sett down as a cause of sterility; but it is well known that some females, who have for years suffered from leucorrhoeal discharge, have conceived and borne children. M. Donné thinks that this fact is explicable on chemical principles. He has observed that the zoosperms on which fecundation depends, live and are active in the vaginal secretion on some occasions, while their movements are at other times speedily arrested. In the latter case, he has found the mucus strongly acid, and he considers that this may act noxiously, and destroy the zoosperms. The uterine mucus is alkaline, and in general the zoosperms are unaffected by it: in cases, however, where it was strongly alkaline, their motions were also destroyed. (Cours de Microscopic, 330.) Further observations are required before this theory can be admitted. The physiology of conception, as to the precise time and circumstances under which it occurs, is altogether a mystery (ante, p. 613). Well-organized and healthy women remain sometimes married for years without bearing children: when, without any apparent change of habit, they become impregnated, even after a barrenness of fifteen or twenty years. Any diseased condition of the system is unfavourable to impregnation, and à fortiori diseases affecting
the uterus or ovaries. Of all these diseases, chronic endo-uteritis, or what may be called irritable uterus, is, in Mr. Whitehead's opinion, one of the most frequent causes of sterility. (On Abortion, 400.) This view is also supported by Dr. W. Cumming, of Edinburgh. His observations tend to show that a diseased state of the lining membrane of the uterus is a frequent cause of temporary sterility. It may be removed by proper treatment (Lancet, May 12, 1855, p. 480). Change of air and climate has in some instances alone sufficed to remove sterility, probably by relieving a diseased condition of the generative organs. It has been remarked, too, of males and females, that there has often been a return of procreative power after recovery from an attack of fever (ante, p. 675). On the whole, the physical and irremediable causes of sterility in the female are not so apparent as in the male, because in the former the generative apparatus is placed internally, and slight changes in its various parts, sufficient to produce permanent sterility, cannot be determined by an examination.

Legal relations of the subject. Divorce.—Sexual malformation, involving impotency or sterility, constitutes one of the canonical impediments to marriage, and if matrimony be contracted by a party labouring under such malformation, the contract is voidable. Canonists have reckoned fourteen impediments to matrimony, enumerated in the following quaint hexameters. (Poynter's Doctrine, 84):—

“Error, conditio, votam, cognatio, crimen,
Cultus disparitas, vis, ordo, ligamen, honestas,
Si sis affinis, si forte coire nequibus,
Si parochi et duplicis desit præsentia testis,
Raptare sit mulier, parti nec redditu tute,
Hae facienda vetant cannubia, facta retractant.”

In the marriage contract there is implied a capability of consumption, and an incapacity in either party in this respect constitutes a ground for annulling the agreement. “Viri et mulier sse conjunxerint, si postea dixerit mulier de viro quod non possidet coire cum eo, si potest (per verum indiciem) probar quod verum sit, accipiat alium (Caus. 23). Quia matrimonium ordinatum silent non solum ad evitandum fornicationem, sed etiam ad proles procreandas: si matrimonium (tale quale) fuerit, inter virum et mulierem de facto solemnizatum, qui omnino inhabiles sunt, non propter etatem, sed propter aliquod naturale impedimentum ad proles suscitandas, utpote propter impotentiam et frigiditatem, maleficentiam, et similia, quæ ipso jure reddat hujusmodi matrimonium nullum. Hæc impedimenta naturalia aliquando contingent tam in muliere quam in viro et pars gravata agere potest in causâ nullitatis matrimonii.” (Oughton, tit, 193, sec. 17.) As to presumed incapacity from age, the law takes no cognizance of
LEGAL PROOFS OF STERILITY.

it. The Pappian law of the reign of Tiberius forbade women under fifty to marry men of sixty, and vice versa; but it is now known that females are prolific beyond fifty, and males beyond sixty.

The impediment constituting impotency may arise either from malformation, from that which the law calls frigidity of constitution, or any physical cause of whatever nature which may render intercourse impossible. When the physical defect is not apparent and irremediable, a continued cohabitation of three years is required before a suit can be entertained (Ayliffe's Parergon; but according to Oughton—"hee triennalis expectatio non est necessaria ubi statim possit constare de impotenti coeundi." Suit for a sentence of nullity may be promoted by either party, and the medical proof required to found a sentence must be such as to satisfy the Court that the incapacity pleaded was in existence at the time of the marriage, and that it still remains without remedy. There should be no delay in instituting the suit and there should be proof that the impediment was not known to the complaining party at the time of the contract. A longer delay in making the complaint is allowed to a female, without prejudicing her case, than to a male, by reason of the modesty of her sex. In a case which came before the Ecclesiastical Courts in 1845, a singular question arose whether, when there was a capacity of intercourse on the part of a female, with a certainty that from physical defect it could never be prolific, this was sufficient to entitle the husband to a divorce. The female was examined by Drs. Bird, Lever, and Cape; and they reported that the sexual organs were undeveloped, like those of girls who had not reached puberty, that the vagina was only three quarters of an inch in depth, and that there was no uterus. They stated that sexual intercourse might take place in an imperfect way; but that conception could not result. On a second examination, seven months afterwards, it was found that the vagina had become elongated, and had then a depth of two inches; but there were no medical means of improving its condition or of removing the defect. It was contended for the husband that the defect was natural and irremediable, and that he was entitled to a sentence of nullity of marriage. On the part of the wife, it was insisted that in order to entitle a party to this sentence, there must be an utter impossibility of sexual intercourse. The case, it was argued, was one of mere sterility, which was no ground for a sentence. Actual consummation had taken place. Dr. Lushington, in pronouncing judgment, said, that mere incapability of conception is not a sufficient ground whereon to found a decree of nullity. The only question is, whether a female is or is not capable of sexual intercourse; or, if at present incapacitated, whether that incapacity admits of removal. A power of sexual intercourse is necessary to constitute the marriage-bond; and this intercourse
must be ordinary and complete, not partial and imperfect; yet it would not be proper to say that every degree of imperfection would deprive it of its natural character. If it be so imperfect as to be scarcely natural, it is, legally speaking, no intercourse at all. As to conception, there is no doubt that the malformation is incurable. If there were a reasonable probability that the female could be made capable of natural coitus, the marriage could not be pronounced void: if she could not be made capable of more than an incipient, imperfect, and unnatural coitus, then it would be void. Dr. Cape stated that under present circumstances there could only be restricted and limited connection; it could not be called perfect and complete. The vagina might possibly become a little more elongated, but this would expose the female to danger. From these facts the marriage was pronounced null and void. (See American Journal of Med. Sci., Jan. 1848, 305.) Hence we may infer, that if the vagina had been of its natural length, notwithstanding the absence of the uterus and the impossibility of conception, a sentence of nullity would not have been pronounced. This is rather conflicting with the doctrine, that the main object of a marriage, valid in law, is ad proles procreandas.

The nature of the medical evidence required on these occasions will be best understood by the following extract from Oughton: — "Ad probandum defectus judex compellere potest virum ad exhibendum prae sentiam suam et ad ostendendum in aliquo loco secreto (per judicem assignando) pudenda sua, seu illos corporis defectus quos mulier obiectit (si ex inspectione corporis apparecer possint), medicis et chirurgis peritissi prius judicis aliter in prae sentia partis adversae, de diligenter inspiciendo virum et de referendo in scriptis eorum judicium juratis. Et si medicorum et chirurgorum judicium sit quod morbus vel defectus viri fuerit insanabiles et incurabiles (tamen tenentur in relatione eorum judicium ipsum morbum seu defectum specificare nec circumveniat Ecclesia), et quod in eorum scientiâ, doctrina, experientiâ morbus aut defectus hujusmodi nullâ re aut arte medicâ curari possit, mulier obtinebit in causâ: hoc addito et allegato ex parte mulieris, quod ipsa sit juvenis et ad procreationem apta, et quod per tres annos insimul per nocturnum, et quod, quamvis a marito cognoscis cupiebat, ab eo tamen cognita non fuit nec cognoscis potuit. Et si defectus non possunt directe per medicos et chirurgos juratos, judicari aut decerni; vel forsan dubia sit eorum relatio; allegeetur ex parte mulieris, non solum quæ ultimo recitata sunt, sed etiam hoc addito: — Quod sit virgo intacta nec a quoquam cognita. Et ad hoc probandum judicialiter jurandum sunt obstetricæ ad inspiciendum mulierem, an vera sint haec allegata. Et si judicio hujusmodi obstetricæm, reperta fuerit virgo, saltum feminâ intacta nec a quoquam cognita; et si vir non possit aliquos defectus objicere contra
uxorem, ob quos cognosce non possit; hanc dictarum mulierum relatio cum judicio medicorum et chirurgorum (quavis dubio) maecum ex eis praeditis indicies (videlicet in eo quod mulier sit juvenis, et quod concubuit cum viro per triennium, ac quod ex aspectu apta et idonea videatur ad procreationem) sufficit ad divertium; seu potius ad pronunciandum nullum ab initio matrimoniumuisse inter hujusmodi personas; casque ab invicem, et ab omnibus inter se a se conjungali, liberas et immunesuisse et esse. Et nullum quod si defectus objiciat contra mulierem probandi sunt, isto modo per inspectionem et relationem.

A case came before the Vice-Chancellor's Court, in February 1845 (Wilson v. Wilson), in which the female produced medical certificates to prove that she was "virgo intacta!" In drawing up such a certificate, a medical reporter should bear in mind that females have become pregnant with what is commonly regarded as the chief sign of virginity intact. Indeed, the division of the hymen has been often rendered necessary for the delivery of the child. Negative evidence of non-consummation from the physical condition of the female, is therefore of much less value, ceteris paribus, than the affirmative evidence from the existence of a physical defect in the male.

When the defect is not apparent on examination, the case is attended with considerable difficulty. Divorce has, however, been granted even in these cases, when the husband has acknowledged his incapacity, and when, notwithstanding cohabitation for some years, this admission has been confirmed by an examination of the wife. Even when the male organs do not appear well developed, and sexual desire is absent, great caution is required in drawing up a report. In the case of Bury, the marriage was dissolved on the ground of impotency; but this man afterwards married, and had issue,—a fact which proved that "ecclesia circumveniatur." This gave rise to a difficult question; for it was contended, if the divorce was null, the second marriage was unlawful and the issue illegitimate. It was decided, however, that the second marriage was only voidable; and that, until dissolved, it remained a lawful marriage, and the children during coverture were legitimate. In investigating a case of this kind, when there is no apparent physical defect or malformation, it is necessary to examine the bodily state of the individual, whether he be effeminate, or have about him any or all of the usual marks which attend a virile state. In the latter case the impotency may be temporary; and it would be decidedly unsafe to pronounce an opinion adverse to the existence of a procreative power.

From these considerations, it will be perceived that, in order to justify a suit of divorce, on the ground of impotency or sterility,
the impediment to intercourse or procreation must be apparent and irreparable; it must also have existed before the marriage of the parties, and have been entirely unknown to the person suing for the divorce: if it has supervened after the marriage, this is no ground for a suit. The nature of the impediment is to be determined by private medical opinions or affidavits, based on an examination of both parties. There is one remarkable circumstance with respect to these cases; namely, that in nearly all of them, the suit is by the female against the male; although there is no reason whatever to suppose that impotency and sexual malformation are more common in males, than sterility in females. We rarely hear of a man instituting a suit of divorce on the ground of sterility (incapacity) in the wife; it is, I believe, in most instances, that the wife promotes the suit on the ground of impotency in the husband. The difficulty of establishing incapacity in the female, and the facility of proving impotency from physical causes in the male, may probably account for the difference. Suits of this kind are sometimes instituted many months and years after the union of the parties; but it is pretty certain that the desire for separation in these cases often depends on some other cause, which the law would not recognize as sufficient of itself, while it would admit the plea of impotency. The French law very judiciously applies the principle of condonation to such cases, so that no suit for nullity of marriage can be entertained, if cohabitation has continued for six months after the discovery of the personal defect. This appears to me more consistent with justice than our own law; but practically these suits, after protracted cohabitation, are always regarded with great suspicion.
RAPE.

CHAPTER LVI.

Nature of the crime. Sources of medical evidence.—Rape is defined in law to be the carnal knowledge of a woman by force, and against her will. In ancient times it was punished by castration—a punishment which, according to Dr. Griffiths, is still retained in Virginia and Missouri, when the crime is perpetrated by a coloured man on a white woman, but not vice versa. The Roman law on which our ancient law was founded was to this effect—Rapta raptoris aut mortem aut indotatas nuptias optet, upon which there arose what was thought a doubtful case: "Una nocte quidam duas rapuit: altera mortem optat, altera, nuptias! For a long period it was punished as a capital crime in this country, but transportation for life was substituted for this punishment by 4 and 5 Vict. c. lxi. s. 3. Since this change was made in the law, it has been alleged, on good authority, that the crime has undergone a considerable increase. On the average of four years, rapes increased 57 per cent. (Law Times, Jan. 4, 1845); and it was stated officially in Parliament, in 1847–8, that the increase had actually amounted to 90 per cent. since the abolition of capital punishment! Medical evidence is occasionally required to support a charge of rape; but it is seldom more than corroborative, the facts are in general sufficiently apparent from the statement of the prosecutrix. There is, however, one case in which medical evidence is of some importance; namely, when a false
accusation is made. In some instances, as in respect to rape on young children, the charge may be founded on mistake; but in others there is little doubt that it is often wilfully and designedly made for motives into which it is here unnecessary to inquire. Professor Amos has remarked, that for one real rape tried on the Circuits, there were on the average twelve pretended cases! In some few instances, these false charges are set aside by medical evidence;—but perhaps in the majority they are developed by inconsistencies in the statement of the prosecutrix herself. I am informed that in Scotland, where there is a public prosecutor and a careful preliminary inquiry, false charges of rape are exceedingly rare. The consent of the female does not excuse or alter the nature of the crime when she is under ten years of age, since consent at this period of life is invalid; and the carnal knowledge of such a female is rape in law. Even the solicitation of the child does not excuse it.

The duty of a medical witness on these occasions is very simple; and perhaps this will be best understood by considering the subject in relation to females at different ages. On being called to examine a person on whom a rape is alleged to have been committed, the first circumstance which the practitioner should notice, is the precise time at which he is summoned,—taking an early opportunity of comparing his watch with some neighbouring clock. This may appear a very trivial matter, and one wholly irrelevant to the duties of a medical practitioner; but it is to be observed, that the time at which a surgeon is required to examine a prosecutrix may form a material part of the subsequent inquiry. It will be highly important to a person accused, if it can be proved that the female did not take the earliest opportunity to complain; and it may be also the means of defeating an alibi falsely set up by an accused person in his defence.

Medical evidence of rape may be derived from four sources:—1. Marks of violence about the genitals. 2. Marks of violence on the person of the prosecutrix or prisoner. 3. The presence of stains of the spermatic fluid, or of blood, on the clothes of the prosecutrix or prisoner. 4. The existence of gonorrhoea or syphilis in one or both. This evidence will vary according to the following circumstances:—

ON INFANTS AND CHILDREN.

The sexual organs should in these cases present traces of injury if the crime has been completed, and there has been any resistance on the part of the child: for it is impossible to conceive that forcible intercourse should take place without the production of ecchymosis, the effusion of blood, or a laceration of the pudendum. It has been propounded as a serious question, whether a rape can be perpetrated on a child of this age by an
adult man; and medical witnesses at trials have been found to adopt diametrically opposite views on this point. For the legal establishment of the crime, proof of penetration only is demanded; and it would appear from an old decision in the case of *Rex v. Russen*, that a degree of penetration so slight as not to injure the hymen would be sufficient to complete the crime. In the case alluded to, the hymen of the child was proved to be entire, and under the direction of the judge, the prisoner was convicted and executed. This trial took place in 1777; but the late Baron Gurney subsequently held, on a trial which took place before him, that there must be a sufficient penetration of the male organ to rupture the hymen; and, unless this membrane was found ruptured, the crime would not be complete in law. (*Rex v. Gammon*, Archbold, Crim. Plea. 406.) This decision was afterwards overruled by the judges, in a case reserved for their consideration by Coleridge J., and reported in 9 Carrington and Payne. (See also the case of *Reg. v. Lines*, 1 Carrington and Kirwan's Reports.) It is now, therefore, an admitted principle, that a sufficient degree of penetration to constitute rape in law, may take place without necessarily rupturing the hymen; but there must be medical evidence to show that, in a special case, there was actual penetration: — the degree of penetration being quite immaterial. It is true that there could not be a complete introduction of the adult male organ into the vagina of a child without a rupture or laceration of the soft parts; but the absence of such marks of violence would not justify a medical witness in denying the perpetration of the crime, since the law does not require proof of a complete or of a violent introduction. Penetration to the vulva is sufficient.

**Proofs of penetration.** — In a case brought before a magistrate a few years since, the evidence left no doubt that the crime had been committed on the person of a girl about ten years old. The surgeon stated that there were considerable marks of violence about the pudendum, but completion (i.e. penetration) was, in his opinion, physically impossible on a child under ten years of age. Upon this evidence the charge of felony was abandoned. In the following case the child was older, but the facts bear immediately upon the question which we are here discussing. It was tried at the Central Criminal Court, March 1843; and the particulars were communicated to the profession by Mr. Adams. (*Lancet*, March 25, 1843.) A man was charged with a rape upon his own child, aged fourteen. Mr. Adams examined the child about two days after the alleged perpetration of the crime; and he found no injury about the vulva or adjacent parts, and the hymen was unruptured. He gave a positive opinion at the trial, that no rape had been committed. Two other medical witnesses, men of experience and integrity, stated their belief that the crime had been perpetrated. It appears that they had exa-
RAPE ON CHILDREN. MARKS OF VIOLENCE.

mained the child soon after the alleged offence, and a day or two before Mr. Adams. The prisoner was acquitted of the rape, but found guilty of the assault. The absence of any marks of injury about the vulva, so short a time after the alleged criminal act, and the fact of the hymen being unruptured, in some measure justified the opinion of Mr. Adams, that there was no medical proof of a rape having been committed: at the same time he candidly restricts his opinion, by saying, that if by rape we are to understand penetration to the vulva, then was it effected; but there was no evidence to show vaginal penetration: on the contrary, the unruptured state of the hymen in a forcible intercourse was against this view. The only remark which this case requires is, that the statute law says nothing about the rupture of the hymen as a necessary part of the evidence: it merely requires proof of penetration. This may occur, and the hymen remain intact. The distinction here drawn by the witness has no real existence. From the decisions of our judges, vulval penetration, whether with or without violence, is as much a rape as vaginal penetration.

In Scotland this question came formally before the judges in the case of Macrae. (High Court of Justiciary, 1841.) It was insisted by the prisoner's counsel, that there should be proof of full and complete penetration; and there was no sufficient evidence to show that penetration had taken place into the canal of the vagina beyond the vulva. Lord Meadowbank charged the jury to the effect, that the evidence of the prisoner's guilt was complete; the scientific and anatomical distinctions as to where the vagina commenced, were worthless in a charge of rape; and that by the law of Scotland it was enough if the woman's body were entered. In a case like this, where there was no evidence of emission, and the girl was young, he did not consider it necessary to show to what extent penetration of the parts had taken place, — or to prove that it had gone past the hymen, into what was anatomically called the hymen, or even so far only as to touch the hymen. The prisoner was convicted. (Cormack's Edin. Jour., January, 1846, p. 48.)

Marks of violence.—When, as in the case above related, there are no marks of violence or physical injury about the pudendum of a child, whether because none originally existed, or they had existed and disappeared in the course of time, a medical witness must leave the proof of rape to others. He can only answer questions of possibility or probability, according to the special facts proved. It is, however, in all cases his duty to be very guarded in giving an opinion that a rape has been perpetrated, when there is a total absence of marks of violence on the genitals. It is true that rape in a legal sense may be perpetrated without necessarily producing such marks on a child: but then the proof of the crime will not depend on medical evidence only. The ab,
sence of marks of violence on the genitals, when an early examination has been made, furnishes a strong presumption that rape has not been committed on these young persons. It is obvious that a false charge might be easily made and sustained, if medical opinions were hastily given on the statements of a mother and child, when there was no physical appearance to corroborate the accusation.

On the other hand, if marks of mechanical violence be present, they must not always be hastily assumed as furnishing proof of rape; for cases are recorded in which such injuries have been purposely produced on young children, as a foundation for false charges against individuals with a view of extorting money. The proof or disproof of facts of this kind must rest more upon general than on medical evidence, unless the injuries obviously indicate the use of some weapon or instrument. It should be remembered, that the hymen is not always present in young children:—it may be, according to some, congenitally deficient, or, what is more probable, it may have been destroyed by ulceration, or suppurative inflammation of the parts,—a disease to which female infants of a scrofulous habit are very subject. The mere absence of the membrane, therefore, can afford no proof of the perpetration of the crime, unless we find traces of its having been recently torn by violence.

Other and more important deductions may, however, be drawn from the presence of severe injuries to the genitals, i.e. of rupture, or laceration of the vagina or perineum. It is difficult to obtain accurate medical reports of these cases as they occur in England: but it is quite clear that the male organ may produce much physical injury whether the child does or does not resist the attempt. Dr. Chevers, in referring to Indian experience, says that, in a large proportion of rapes on children, it was very clearly proved that rather severe injury had been received. In the Nizamat Adawlut Reports, 1853-5, there are several instances recorded, in which the vagina was lacerated. Out of 66 trials for rape there were 52 convictions: and in one half of these cases the females were under the age of twelve. In one case of a girl, at twelve, there was a rupture of the lower part of the vagina to the extent of half an inch. In another, a child of six, but apparently much younger, had suffered, as a result of rape, from rupture of the hymen and laceration of the perineum and vagina. In one instance the violence proved fatal, but the medical particulars were not given (Med. Jur. for India, p. 468). I have already observed that injuries have been sometimes intentionally produced on the genitals of infants and children by mechanical means,—with a view of extorting money in laying false charges of rape. Dr. Chevers, from whose work I have quoted the above facts, states, on the authority of a missionary well acquainted with the habits of the natives of Cal-
cutta, that mechanical means are commonly employed even by
the parents of immature girls, to render them apte viris, es-
pecially by the use of the fruit of the plantain. In one instance,
a man was convicted of rape who, according to the evidence, had
previously used a small stick—ad debstruendum viam. This
led to effusion of blood, but no permanent injury.

In April 1840, Dr. Brady communicated to the Dublin
Association of Physicians, a case of rape on a female infant only
eleven months old, in which the violence to the genitals proved
fatal. During the march of a regiment to Templemore, the
prisoner Hume, a soldier who was with the sick car, took the
child from its mother (Mary Hall) to carry it some way for her.
The child was quite well when he took it: he walked on quickly
and was out of the mother's sight in half an hour. When she
came up, he had the child standing on the grass facing him, and
he was bent over it: with one hand he held the child's petticoats
up, and his other hand was covered with blood. He told the mother
that the child was ill and passing blood. The mother rolled it
in her shawl, and carried it until they reached Templemore when
she went to an apothecary; but no examination was made, and
it was not until the next morning that in washing the child the
marks of violence were seen. This was the substance of the
mother's evidence, which was uncontradicted at the trial. A
surgeon examined the child twenty hours after the alleged
outrage. It was then in a state of complete collapse, and it died
in a few hours. On examination, all the external parts of
generation were found in a torn state and violently inflamed;
the perineum was torn nearly quite through: the nymphæ, and
the mucous lining of the labia, and clitoris were likewise lacer-
ated, so that the whole presented the appearance of a large
lacerated wound in a high state of inflammation. After death,
besides the above-mentioned appearances, the vagina was found
greatly dilated and torn from its attachment to the neck of
the uterus posteriorly, making a large opening into the cavity of
the abdomen, in which a quantity of bloody serum was effused

In January 1858, a girl seven years old was brought into Guy's
Hospital, owing to injuries resulting from the perpetration of rape,
by a boy under seventeen years of age. About half an hour had
elapsed; she was then examined by Mr. Hicks, the house
surgeon, and he found that there was complete destruction of the
hymen, with a laceration of about one eighth of an inch ex-
tending into the perineum. There had been profuse bleeding,
as the clothes were saturated with blood. There was then no
complaint of pain, and there were no scratches or marks of
violence on any part of the body. There was no discharge of a
purulent kind. The child was of a serofulous habit: but she was
not suffering from vaginitis, and appeared in other respects per-
fectly healthy. I saw the girl with Mr. Hicks about forty-eight hours after the occurrence: the bleeding had then ceased, and the extent of the lacerations was very perceptible. There was no discharge of any kind from the vagina, and no inflamed or swollen condition of the parts. The boy was examined by Mr. Hicks about an hour after the perpetration of the rape, and although he had been under strict custody and had had no opportunity of changing his clothes, there was no blood found about his private parts, or on his clothing. It is probable as the boy was interrupted in the act by the screaming of the girl, that he suddenly withdrew after having caused the laceration, and that the bleeding was an after effect, as a result of coxing from the small vessels. This is an important fact, because had not the circumstance been known, the absence of blood on his person might have been construed into a proof of innocence.

These cases occasionally present great medico-legal difficulties. The following charge of rape was tried before Wightman J., at the Liverpool Winter Assizes of 1857. A man named Greenwood was indicted for the wilful murder of Mary Johnson, a healthy child under ten years of age. It appeared in evidence that the prisoner slept with the child in a room in which there were other persons. On the third day after this she complained of great pain; on the fourth day she was examined by a medical man, and then she stated that the prisoner had had connection with her on the night she slept with him (Oct. 22), and had hurt her greatly. Mortification of the genitals set in, and the girl died. The medical evidence was to the effect that the deceased had died from mortification of the genitals produced by rape and venereal disease. The prisoner was convicted of manslaughter and sentenced to penal servitude for life. I am indebted to Mr. Wilde, of Dublin, for some additional particulars. It appears from the testimony of two medical men who examined deceased on the fourth or fifth day, that the perineum was ruptured; the hymen lacerated; there was ulceration of the labia, extending to the rectum, accompanied by profuse purulent discharge from the vagina. Mortification set in on the 29th of October, and the girl died on the 5th of November. On inspection, almost all the soft parts within the pelvis were in a state of mortification, and the sloughing had extended over the sacrum and nates. The mucous lining of the bladder showed patches of inflammation; and there was a purulent discharge over it. The prisoner had warty excrescences and syphilitic sores on the penis.

The proof of connection depended on the deposition of the girl, which was taken by a magistrate before her death, as well as on such medical inferences as the above-mentioned state of facts would justify.

Some cases quoted from Dr. Chevers (ante, p. 696.) show that rupture of the perineum and other severe injuries may be a re-
sult of rape on children of this tender age. The communication of syphilis is also a proof on which much reliance is justly placed. The girl complained of feeling unwell on the third day, and when medically examined on the fourth day it was found that she was affected with syphilitic disease. This taken in conjunction with the fact, that before sleeping with the prisoner she had not complained of any pain or uneasiness in the genitals, appears to connect closely the date of her illness with the time at which the prisoner had had an opportunity of intercourse. It was also proved that he was affected with syphilis. It is a little singular that with a ruptured perineum, if ruptured by intercourse, the girl did not complain or show some difficulty of walking on the first or second day; and there were no marks of bleeding. It is difficult to suggest a reason why, if thus injured, she did not make earlier complaint, or why the pain which such injuries would produce did not betray her condition. The extensive sloughing that followed may have been aggravated by an unhealthy state of body. There was no reason to suppose that the perineum was ruptured before she slept with the prisoner, and there was nothing to cause its rupture subsequently. The girl may have been labouring under vaginitis, or _noma_, but that would not have altered the character of the offence — since if the intercourse in any way accelerated death by causing rupture, and as a result of mechanical injury had led to violent inflammation and fatal sloughing of the parts around, the prisoner would still be guilty of manslaughter. That there was intercourse, appears clear from the statement of the girl and the medical evidence; and, although it is rare that injuries of this kind destroy life, yet there is nothing actually inconsistent with medical experience that they should cause death. Ordinary vaginitis is not fatal or likely to prove so except in those cases in which the body is in an unhealthy condition.

In a case which occurred to Dr. Bullen, a girl of seventeen, was violated by several men in succession: she then became insensible and was unable to state how often the act had been perpetrated. When examined the next day, the genitals were bloody, inflamed, and painful, the hymen was ruptured, the fourchette torn, and the labia and perineum presented a dusky inflammation. In spite of treatment, ulceration followed, and the clitoria, nymphae, perineum, labia, and mons veneris sloughed away, leaving the pubis exposed. After a long illness the ulcer healed, and she left the infirmary. At no period were there symptoms of syphilis. Such a state of parts, — obviously a result of violence, might have been ascribed to _noma_ or malignant ulceration and mortification of the genitals, as it is observed in some eruptive fevers. (Dub. Med. Press, March, 1840. Beck's Med. Sur. vol. i. p. 160.)

*Purulent discharges from the vagina.*—Vaginitis, Infantile
Leucorrhoea.—The existence of a purulent discharge from the vagina, as a result of vaginitis or inflammation of the vagina, has been erroneously adduced as a sign of rape in these young subjects. The parents, or other ignorant persons, who examine the child, often look upon this as a positive proof of impure intercourse; and perhaps lay a charge against an innocent person, who may have been observed to take particular notice of the child. Some cases are reported, by which it would appear that individuals have thus narrowly escaped conviction for a crime which had really not been perpetrated. Dr. Percival, in his Medical Ethics (3rd ed. 1849, p. 117), has related a case which has been the subject of frequent quotation and comment in reference to false charges of rape. A girl aged 4 was admitted into the Manchester Infirmary in February 1791, on account of a mortification of the female organs and general depression of strength. She had been in a bed with a boy fourteen years old, and there was reason to suspect that he had taken criminal liberties with her. The mortification increased and the child died. The boy was tried at the Lancaster Assizes, but was acquitted on sufficient evidence that several instances of a similar disease had appeared near the same period of time, in which there was no possibility of injury or guilt. In one of these cases there was typhus fever with a mortification of the pudenda. There was no cause discoverable on inspection. The lumbar glands were of a dark colour; but all the viscera were sound. This case is distinguished from that of Greenwood above quoted, by the presence of laceration in the latter case, and the occurrence of a discharge on the third or fourth day after the alleged intercourse.

A purulent discharge is very common as a result of vaginitis (inflammation of the vagina) in young children. It often arises from dentition, or local causes of irritation—as worms or uncleanly habits, and is observed especially in children of a scrofulous habit. It is frequently met with in girls up to six or seven years of age: and children thus affected have been tutored to lay imputations against innocent persons, for the purpose of extorting money. This state may commonly be distinguished from the effects of violence, either by the hymen being entire—or by the non-dilatation or laceration of the vagina or perineum—by the red and inflammatory condition of the mucous membrane,—and the abundance of the purulent discharge, which is commonly much greater than that which takes place as a mere result of violence. Capuron mentions two cases, in which charges of rape on children were falsely made against innocent persons, on account of the existence of a purulent discharge, the nature of which had been mistaken. (Méd. Lég. des Accouchements, 41.)

This subject long since attracted the attention of Sir Astley Cooper, Mr. Lawrence, Mr. Kinder Wood and other medical men: but there is still much popular ignorance in reference to it, and
false charges of rape on children are not unfrequently made. Mr. Kesteven has reported a case in which a discharge from the vagina of a child nine years of age, was considered by the parents to indicate that intercourse had been had with her. There was no mark of contusion or violence on or about the pudendum or in the vagina, and the case was very properly pronounced to be one of vaginitis. (Med. Gaz, vol. xlvi. p. 372.) A similar case was referred to me in which a soldier was supposed to have infected a child: but an investigation showed that it was a purulent discharge depending on inflammation of the vagina. Charges of rape are sometimes rashly made in these cases, either in the absence of, or in actual defiance of, a medical opinion. Mr. Hamilton has reported an instance of this kind (Dub. Med. Press, May 4, 1853, p. 276), in a child aged 7. There was an inflammatory state of the vagina, and a yellowish discharge issued from it; but there was no sign of rupture, contusion, or any mark of violence. The medical opinion was to the effect that there was nothing to show that any violence had been used to the child, or that she had been infected with the venereal disease. Nevertheless, the accused was placed on his trial; but the evidence of the child broke down, and the man was acquitted. In the same paper, Mr. Hamilton relates a case in which syphilis was communicated to a girl aged 6 by a boy aged 19. In this case the accused was found to have numerous chancres around the orifice of the prepuce, and on examining the little girl, there were chancrous excoriations on the inside of the labia. Other syphilitic symptoms manifested themselves. The prisoner was convicted.

The subject of infantile leucorrhœa has been fully investigated by Mr. Wilde, of Dublin (Medico-legal Observations, &c. 1853). This gentleman has collected numerous cases illustrating in a remarkable manner the great danger to which innocent persons are exposed by reason of false charges of rape on children. Two of these are especially noticed in his essay. A charge was raised against a respectable man, that he had had intercourse with, and produced disease in, two children. The day and hour were circumstantially given, extorted as it appears from the children by the parent, and the man was put upon his trial. The appearances were such as are usual in these cases,—a purulent discharge from the vagina with some excoriation, but no bruise, laceration, or mark of violence on the pudendum. There had not been any penetration of the vagina. The charge against the prisoner, although unsupported by any affirmative circumstances, received some strength from the admission made by one medical witness for the prosecution, namely, that the appearances might have been the result of violence,—and that the discharge might have been produced by friction with the member of a healthy man. (Wilde, op. cit. p. 14.) It was proved that the prisoner was not affected either with gonorrhœa or syphilis. Drs. Geoghegan,
Churchill, and other medical witnesses of repute, gave testimony to the effect that the child was labouring under an ordinary form of disease, and that there was no medical indication that it had been subjected to any kind of violence. This testimony was not considered by the Court to furnish a complete answer to the charge, since it was inferred that the appearances on the child might have been caused by the accused, without any marks of violence being left on the pudendum. So strong was this feeling, that, had the case rested here, it is probable that the accused would have been convicted upon the unsupported statement of the child. An alibi was, however, clearly proved, and he was acquitted. In this case, it will be perceived it was alleged that a man who laboured under no disease had caused a purulent discharge in a child. At the same time, it was admitted that the pudendum had sustained no violence whatever. Medically speaking there appears to have been not the slightest pretence for charging the accused with the perpetration of rape. The appearances might have been and might not have been caused in the manner suggested. Under such loose medical evidence as this no person is safe. An acquittal from an unfounded charge must depend upon the person accused being able to prove a distinct alibi, i.e., he must prove his innocence. The statement of the child may be simple and artlessly made. At this tender age, a girl may be easily induced, by the fear of punishment and by the aid of leading questions put by a parent, to admit that some one had committed an assault upon her. The statement once made may be persevered in, and its inconsistency may not always be brought out by cross-examination.

If the child be really labouring under syphilis or gonorrhoea, this is, ceteris paribus, evidence of impure intercourse, either with the ravisher or some other person; but we should be well assured, before giving an opinion, that the discharge is really of a gonorrhoeal, and not simply of a common inflammatory, character. The party accused, as in the case just related, might be at the time free from that disease, or, if labouring under it, then we should expect that the discharge had suddenly made its appearance in the child with its usual severe symptoms, at a certain interval of time after the presumed intercourse; i.e., from the third to the eighth day. When these conditions do not exist, it is extremely difficult to form a medical opinion on the subject, since there are no certain means, by the microscope or otherwise, of distinguishing common purulent discharges from those which are gonorrhoeal. Under these circumstances, if the charge be well founded, proof can only be derived from non-medical sources. A case occurred to M. Biasly, in which a mere mucous discharge in a girl was pronounced to be syphilitic, and the party who was falsely accused of rape narrowly escaped conviction. (Briand, Man. Complet de Méd. Lég., 1846, 81.) We should further distinctly satisfy ourselves that
the gonorrhoea in the child, if it exist, could not have arisen from infection by any accident irrespective of intercourse. This limitation is rendered necessary by the publication of a report of two cases by Dr. W. B. Ryan (Med. Gaz. xlvii. p. 744), in which two sisters, one of one year, and the other of four years of age, received the infection by reason of being washed in a vessel with a sponge used by a young woman affected with profuse gonorrhoeal discharge. Dr. Ryan clearly traced the origin of the discharge to this very unexpected accident. Had an accusation of rape been made against a man labouring under gonorrhoea, it is not at all improbable that this condition of the children, resulting from an unsuspected accident, would have been taken as an unanswerable proof of his guilt. Cases of this kind, thus accurately observed, convey an important caution to medical witnesses: i.e. that they should not infer criminal intercourse merely from the existence of a gonorrhoeal discharge, in the absence of marks of violence to the genitals or other strong corroborative proofs.

As a summary of these remarks with respect to purulent discharges, we may observe, that they should never be admitted as furnishing corroborative evidence of rape, except,—1, when the accused party is labouring under gonorrhoeal discharge;—2, when the date of its appearance in the child is from the third to the eighth day after the alleged intercourse;—3, when it has been satisfactorily established that the child had not, previously to the assault, any such discharge. It may be said, however, that all these conditions may exist, and yet the accused be innocent; for a child may, either through mistake or design, accuse an innocent person. This, however, removes the case entirely from the hands of a medical jurist.

In the case of the Queen v. Mosely (Cent. Crim. Court, Sept. 1843), the prosecutrix, a child between twelve and thirteen years of age, charged the defendant with having committed a rape upon her, alleging that she had made all the resistance in her power. Dr. Merriman stated that he examined the prosecutrix two or three days after the alleged offence was committed, but could not give any decided opinion upon the case, although there was every appearance of violence having been used. Another medical witness stated that the prosecutrix had been under his care for the last eight or nine days for a disease (gonorrhoea) with which, in his opinion, she had been infected for a considerable time; and a third proved that the prisoner was not infected with this disease. Dr. Merriman, however, is reported to have said that the prosecutrix was not labouring under the disease when he examined her. It is difficult to explain how this discrepancy on a matter of fact of some importance could have arisen. The jury acquitted the prisoner, probably not trusting to the statement made by the prosecutrix. In another
case, Reg. v. M'Donough (Cent. Crim. Court, Oct. 1843), Mr. French and Mr. Tucker deposed that the gonorrhoea under which the prosecutrix (et. 15) laboured had probably not existed longer than a week,—it might have been of longer standing, but it certainly could not have existed for six weeks, the date at which it was alleged that the rape was perpetrated by the prisoner, and the disease communicated. Upon this evidence the prisoner was acquitted.

The following case was tried at the St. Louis' Criminal Court. A man named M'Comas was charged with an attempt to violate a child et. 9. The evidence against the prisoner was chiefly based on an extorted admission from the prosecutrix, and on the discovery on her clothes of certain stains supposed to have been produced by seminal fluid. The mother examined the genitals, and found them inflamed and discharging matter, although several weeks had elapsed since the alleged attempt. A medical practitioner was called to the girl; he found the nymphae and orifice in a state of inflammation, which might have arisen from some morbid cause; but he was unable to give any positive opinion respecting the nature of the discharge. About eight days after this, the girl was examined by Dr. Stephens: the parts were still much inflamed, and discharging muco-purulent matter. The hymen was uninjured. The defence of the prisoner was, that he was not guilty of the assault, and that he was not labouring under gonorrhoea at the time of the alleged attempt. He was convicted and sentenced to three years' imprisonment. (British American Journal, May 1848, p. 19.) It is not improbable that this was a case of vaginal catarrh mistaken for gonorrhoea; for, as it has been already stated, there are no certain means of distinguishing the two kinds of discharges. The jury, however, appear to have put great faith in the testimony of the prosecutrix. The case was therefore decided by moral circumstances, and not by medical evidence. The existence of an unruptured hymen merely proved that there had not been a violent attempt at carnal intercourse.

With respect to marks of violence on the body of a child, these are seldom met with, because no resistance is commonly made by mere children (see case, ante, p. 697). Bruises or contusions may occasionally be seen on the lower extremities.

ON YOUNG FEMALES AFTER PUBERTY.

When the crime is committed on a female from the age of ten to twelve years, the facts are much the same as those already referred to with respect to children below the age of ten years. There is, however, some difference in the legal complexion of the offence. If carnal intercourse be had with the consent of a female between the ages of ten and twelve years, the offender is
guilty of a misdemeanour only. Above the age of twelve years, the consent of the female does away with any imputation of legal offence. Females who have passed this age are considered to be capable of offering some resistance to the perpetration of the crime; and therefore, in a true charge, we should expect to find not only marks of violence about the pudendum, but also injuries of greater or less extent about the body and limbs. It is probable that in these cases, if the charge were well founded, the hymen would be ruptured, as the intercourse is always presumed to be violent; but there might be some degree of penetration without this being a necessary result, especially if the membrane were small, or placed far up. At any rate a young female at this age may sustain all the injury, morally and physically, which the perpetration of the crime can possibly bring down upon her, whatever may have been the degree of penetration; and for this reason, it is very properly laid down in our law, that the crime consists in the mere proof of penetration. The fact, however, is generally clearly made out by the statement of the female. With respect to marks of violence on the person, the exact form, position, and extent of these should be noticed; because a false accusation of rape may be sometimes detected by the violence being in a situation in which it was not probable that the ravisher would have produced it. When bruises are found, the presence or absence of the usual zones of colour may occasionally throw light upon the time at which the alleged assault was committed. As these marks of violence on the person are not likely to have been produced with the concurrence of the female, they are considered to furnish some proof of the intercourse having been against her will. But the physical appearances of rape about the pudendum may be found, whether the connection has been voluntary or involuntary. Thus rupture of the hymen, laceration of the vagina with effusion of coagula of blood, swelling and inflammation of the vulva, and stains of blood upon the person or dress, may be met with in both cases. In making an examination, the greatest care should be taken by the practitioner to fix a probable date for the marks of injury to the genitals or other parts of the body, as it is by the aid of such observations that the truth or falsity of a charge may be sometimes clearly established.

Unmarried females of the age here supposed are liable to mucopurulent discharges from the vagina, as a result of which the hymen may be destroyed. This kind of discharge arises from inflammation of the vagina (vaginitis), and it has been observed to follow an attack of scarlatina. When it exists, its real cause requires the closest scrutiny. (See remarks by Dr. Barnes, Med. Gaz. xlvii. p. 65.) At a more advanced age, young females are frequently subject to leucorrhoea. These cases are not likely to be mistaken for gonorrhoea; as here the female has it in her power to give some
account of the circumstances, from which a medical opinion may be easily formed.

Defloration. Signs of virginity. — It will be necessary to say a few words respecting the signs of virginity. — A subject upon which, in some medico-legal works, a great amount of poetical discussion appears to me to have been wasted. Independently of cases of rape, this question may occasionally assume a practical bearing in relation to the signs of defloration. In civil cases a medical witness may be asked whether a particular female has ever had intercourse or not. Proof of this fact may be necessary in order to confirm or rebut statements made in evidence. The question may be, not whether a female has had a child or not, for this would resolve itself into a proof whether delivery had or had not taken place: — it may be limited to the probability or possibility of intercourse on her part, at some antecedent period. Now a medical jurist, when consulted in such a case, can only be guided by the presence or absence of the external signs of virginity. The hymen may be intact, but this does not prove non-intercourse, because females have been known to conceive with the hymen uninjured; and an operation for a division of this membrane has been frequently rendered necessary before delivery could take place. (Henke's Zeitchrift der S. A. 1843, ii. 149.) This may be explained by the membrane being hard and resisting, and at the same time small in extent, i. e. only partially closing the vagina. Under opposite conditions, the persistence of this membrane might fairly lead to the inference that the female was chaste, and that there had been no intercourse; but the hymen may be destroyed by ulceration, as a result of inflammation of the genital organs. When the membrane has been thus destroyed by disease or other causes, or when it is congenitally absent, the opinion must be more or less conjectural; for one intercourse could hardly so affect the capacity of the vagina, as to render the fact evident through life, and there is no other datum upon which a medical opinion could be based. The presence of the hymen is of course quite incompatible with the assumption that the female has borne a child. A question of this kind incidentally arose in the case of Fraser v. Bagley (Common Pleas, Feb. 1844). It was alleged by defendant, that the plaintiff, a married man, had had adulterous intercourse with a young female, and that at an antecedent period she had left her home for the purpose of giving birth to a child privately. The late Dr. Ashwell was called upon to examine the party, and he deposed that, in his opinion, the female was a virgin, and had never had a child. (See also Henke, 1844, i. 259.) It is possible, however, that there may be abortion at the early periods of pregnancy, without this being attended with the destruction of the hymen.

This question may become of importance, not only as it may affect the reputation of a female, but the credibility and character of the person who makes the charge of want of chastity. In
1845, a gentleman, then assistant-surgeon in the Bombay Army, was brought to a Court-Martial on a charge of having deliberately and falsely asserted that on several occasions he had had connection with a native female. This was denied by the woman, and evidence was adduced to show that she had still what is commonly regarded as the main sign of virginity, namely, an unruptured hymen. In consequence of this, the gentleman was found guilty, and cashiered. The native female was at the time about to be married, and this rendered the investigation all the more important. An assistant-surgeon, who examined the girl, deposed that he found the membrane of a semilunar form, and tensely drawn across the vagina; and his evidence was corroborated by that of a midwife. The inculpated party took up a double line of defence: 1, That the examination of the female was incomplete; 2, That the hymen, if present, would not justify the witness in saying that intercourse could not possibly have taken place. On the first point, it is unnecessary here to make a remark; but it appeared, from their own admission, that the witnesses had never before examined females with this particular object. Assuming that there was no mistake, it becomes a question whether non-intercourse could in this instance be inferred from the presence of the membrane. Fruitful intercourse, it is well known, may take place without rupture of the hymen. Some instances of this kind were referred to at the Court-Martial; but such cases may be regarded as of an exceptional nature. The real question is, whether, unless the hymen be in an abnormal state, intercourse can possibly occur between young and active persons without a rupture of this membrane. Intercourse is not likely to be confined, under these circumstances, to mere penetration of the vulva. The membrane in this female is stated to have been tensely drawn across the canal, and it was not tough; it was therefore in a condition rendering it most easy for rupture. In the case of an old man, or of one of weak virile power, vulval intercourse might be had without destroying the membrane; but such a case could only be decided by the special circumstances which accompanied it. The presence of the hymen unruptured affords a presumptive but not an absolute proof that the female is a virgin; and if of the ordinary size and shape, and in the ordinary situation, it shows clearly that there can have been no vaginal penetration. Admitting the statements of the examiners to be correct, it is very improbable that this female had had sexual intercourse on several or even on one occasion; hence the imputation on her chastity was unfounded.

In the case of Delafosse v. Fortescue (Exeter Lent Ass. 1853), which involved an action for defamation of character, the plaintiff, a married man, sect. 64, had been charged with committing adultery with a certain female. Several witnesses for defendant positively swore that they had seen the parties in criminal inter-
course. This was denied by the plaintiff; and, as an answer to the case, medical evidence was tendered to the effect that the female with whom the adulterous intercourse was alleged to have taken place had been examined, and the hymen was found intact. In cross-examination this was admitted not to be a conclusive criterion of virginity. A verdict was returned for defendant. The form and situation of the hymen in this case were not described; but it is to be presumed that these were not such as to constitute a physical bar to intercourse, or this would have been stated by the medical witness. Hence the existence of the membrane was not considered to disprove the allegations of eye-witnesses. In the case of Hunt v. Hunt a verdict was obtained at common law against the alleged paramour in a case of adultery, and the damages were assessed at fifty pounds. It was subsequently proved that the lady was \textit{virgo intacta}. So long as there are facts which show that females have actually conceived with the hymen still in its normal state, it is inconsistent to apply the term "virgo intacta" to females merely because this membrane is entire. A woman may assuredly have an unruptured hymen, and yet not be a \textit{virgo intacta}. This can only be decided by the special circumstances proved in each case. Such \textit{virgines intactae} have frequently required the assistance of accoucheurs, and in due time have been delivered of children!

ON THE MARRIED.

The remarks already made apply to married women, with this difference, that when a female has already been in habits of intercourse with the other sex, there is commonly much less injury done to the genital organs. The hymen will, in these cases, be found destroyed, and the vulva dilated. Still, as the intercourse is presumed to be against the consent of the woman, it is most likely that under proper resistance, some injury will be done to the pudendum, and there will be also, probably, extensive marks of violence on the body and limbs. Such cases are generally settled without medical evidence, from the statement of the female alone, corroborated, as it should be, by circumstances. An experienced barrister has suggested to me that this statement regarding the presence of marks of violence on the pudendum of a married woman, on whom a rape is alleged to have been committed, requires some qualification. He informs me that he was concerned in the prosecution of two cases of rape on married females, in which the crime was completed in spite of the resistance of the female, and there were no marks of violence on the genital organs. In one (\textit{Reg. v. Owen and others, Oxford Circuit, 1839}), it appears that while an accomplice held the head of the female, with her face downwards, between his thighs, the prisoner had forcible intercourse with the woman.
from behind,—her thighs having been first widely separated. In the second case, an accomplice held the woman down on a bed by her neck, while the prisoner separated her thighs, and thus had intercourse with her. She was examined nine hours afterwards by an experienced surgeon, and he found no mark or trace of violence or injury on or anywhere near her pudendum. There were bruises on her arms, neck, and legs, where she had been forcibly held down. In both of these cases, it will be seen that the woman had not to struggle with a single assailant; and there can be no doubt that if a married woman be rendered powerless by many being combined against her, or if she be rendered insensible by intoxicating drinks, or narcotic vapours, a rape may be perpetrated without any injury whatever to the pudendum. The gentleman to whom I am indebted for the above cases, has suggested that a separation of the thighs in a married woman will cause such a dilatation of the parts, as to render it easy for the male organ to penetrate the vagina without leaving any traces of violence on the labia or the female organs generally. This is undoubtedly the true explanation.

When a charge of this kind is made by a prostitute, it is justly received with suspicion, and the case is narrowly scrutinised. Something more than medical evidence would be required to establish a charge of rape under these circumstances. The question turns here, as in all cases of rape upon adult females, on the fact of consent having been previously given or not. This is the point at which the greater number of these cases of alleged rape break down; and it need hardly be observed, that this question has no relation to the duties of a medical witness;—all that he can do is to establish, occasionally, whether or not sexual intercourse has been had, with or without some violence. It is obvious that there may be some marks of violence about the pudendum, or on the person, and yet the conduct of the female may have been such as to imply consent on her part. We must not suppose, as it appears to be commonly done, that medical proof of intercourse is tantamount to legal proof of rape.

Possibility of perpetrating rape.—Some medical jurists have argued that a rape cannot be perpetrated on an adult female of good health and vigour; and they have treated accusations made under these circumstances as false. Whether, on any criminal charge, a rape has been committed or not, is of course a question of fact for a jury, and not for a medical witness. The fact of the crime having been actually perpetrated, can be determined only from the evidence of the prosecutrix and other witnesses. Still a medical man may be able to point out to the Court circumstances which might otherwise escape notice. Setting aside the cases of infants, idiots, lunatics, and weak and delicate females, it does not appear probable that intercourse could be accomplished against the consent of a healthy adult female, except under the
following conditions:—1. When narcotics or intoxicating liquids have been administered to her, either by the prisoner or through his collusion. It matters not in a case of this kind, whether the narcotics have been given merely for the purpose of exciting the female, or with the deliberate intention of having intercourse with her while she was intoxicated,—the prisoner is equally guilty. (See Reg. v. Camplin, Law Times, June 28, 1845; also Med. Gaz. xxxvi. 433.) The nature of the substance whereby insensibility is produced is of course unimportant. Thus the vapours of ether and chloroform have been criminally used in attempts at rape. In a case which occurred in France, a dentist was convicted of a rape upon a female, to whom he had administered the vapour of ether. The prosecutrix was not perfectly unconscious; but she was rendered wholly unable to offer any resistance. (Med. Gaz. xl. 865.) A dentist was recently convicted of rape under somewhat similar circumstances in the United States, but it was thought that the female had made the charge under some delusion. Even when the state of unconsciousness arises from natural infirmity, as in idiocy or insanity, carnal intercourse with a female is regarded as rape. (Reg. v. Ryan, C. C. C., Sept. 1846.) The female was in this case an idiot, and it was proved that her habits were not loose or indecent. Platt, held that if she was in a state of unconsciousness at the time the connection took place, whether it was produced by any act of the prisoner or by any act of her own (?) any one having connection with her would be guilty of rape. The prisoner was convicted. In Reg. v. White (Northampton Winter Assizes, 1856), the learned judge, in charging the jury, stated that some doubts were entertained whether the crime of rape could be committed (in law) on the person of a woman who had rendered herself perfectly insensible by drink, so as to be unable to make any resistance. He thought it could not be alleged as an excuse for the man. The question was not reserved as the prisoner was acquitted of the rape, and found guilty of an indecent assault.

It may be a question whether a man can have forcible intercourse with a female while in a state of unconsciousness from natural sleep. A man was charged with rape before a Police magistrate, and the prosecutrix swore that he had effected his purpose during her sleep. The bare possibility of the offence being perpetrated under these circumstances cannot be denied; but this admission would only apply to a case where the sleep was preternatural or lethargic. In this instance the female was a prostitute, and the charge improbable; all such cases can be determined only by the special facts which accompany them. The state of the mind during the act of waking from sleep, i.e. when a person is in a half-conscious state, may also give rise to a question connected with rape. In Reg. v. Clarke (York Autumn Ass., 1854), prisoner was charged with having committed a rape on prosecutrix. The woman had been married to her husband six
years, and had had three children. Prisoner took advantage of his absence from home to get into the bed of prosecutrix; about two o'clock in the morning: she mistook him for her husband, and under that mistake allowed him to have intercourse with her. It was only some time afterwards that she found it was the prisoner, and not her husband, who was in bed with her. The jury convicted him on this evidence. The case was reserved by Crowder J., for the opinion of the judges whether the offence amounted to rape, as it was not included in the ordinary definition, i.e. of carnal knowledge by force and against the will of the woman. The psychological question does not appear to have created difficulty, although it may be doubted whether under such circumstances the act could be perpetrated without the tacit consent of a woman. 2. A rape may be committed on an adult female if she falls into a state of syncope, or is rendered powerless by terror and exhaustion. An eminent judicial authority has suggested to me that, in his opinion, too great distrust is commonly shown in reference to the amount of resistance offered by women of undoubted character. Inability to resist from terror, or from an overpowering feeling of helplessness, as well as horror at her situation, may lead a woman to succumb to the force of a ravisher, without offering that degree of resistance which is generally expected from a female so situated. As a result of long experience, he thinks that injustice is often done to respectable women by the doctrine that resistance was not continued long enough. 3. When several persons are combined against the female, in which case we may expect to find some marks of violence on her person, if not on the genital organs (ante, p. 708). 4. A woman may yield to a ravisher, under threats of death or duress, — in this case her consent does not excuse the crime: but this is rather a legal than a medical question. An aged woman can scarcely be expected to resist a strong man. Dr. Chevers mentions a case in which a man was convicted of rape and aggravated assault on a woman of seventy years of age.

*Loss of physical evidence.*—It is necessary to observe, in relation to the examination of adult females, that the marks of rape, however strong in the first instance, soon disappear or become obscure, especially in those who have been already habituated to sexual intercourse. After two, three, or four days, unless there has been a very unusual degree of violence, no traces of the crime may be found about the genital organs. In unmarried females, and in children, when there has been much violence, these marks may persist and be apparent for a week or longer. Supposing at the period of examination no such marks exist, it may be necessary to consider whether there has been time for them to disappear since the alleged perpetration of the offence; but in such cases it is rarely in a witness's power to express an affirmative opinion of the perpetration of the crime: he must leave this to.
be proved by the general and circumstantial evidence. Marks of
violence on the person can never establish a rape; they merely
indicate, ceteris paribus, that the crime has been attempted.

Pregnancy following rape.—It was formerly a debated question,
whether, in a case of real rape, pregnancy could possibly follow;
and this was even proposed as a rude test of the truth of a charge
made by a female! Such a question requires no discussion in
the present day. Conception, it is well known, does not de-
depend on the consciousness or volition of a female. If the state
of the uterine organs be in a condition favourable to impregna-
tion, this may take place as readily as if the intercourse was
voluntary. Even penetration is not absolutely necessary for im-
regnation. (See case by Dr. Oldham, Med. Gaz. xlv. p. 48.)
Mr. Carrington has communicated to me a case in which a
female became pregnant after a rape committed on her by a man
who subsequently married her. The date of intercourse was
accurately fixed, and the child was born after 263 days’ gesta-
tion (see ante, p. 610).

Microscopical evidence.—Of late years, it has been proposed to
add to the medical evidence in rape, the examination of spots or
stains on the linen of the prosecutrix and the accused. (Ann.
d’Hyg., 1834, 210; 1839, 134.) Cases of rape have in general
been tried in this country without reference to this species of
evidence; and it is not easy to perceive how this can be neces-
sary to the proof of the crime in the living, when the present
law of England demands only proof of penetration, and not of
emission. Thus, a rape may be legally completed without refer-
ce to emission; and, medically speaking, it appears quite pos-
ible that there might be marks of emission without any penetra-
tion. Admitting that certain stains of this description are found on
the clothes of an accused party,—Are these to be taken as furnishing
undeniable proof of the legal completion of rape? It appears
to me that without corroborative proofs from the state of the
female organs they cannot be so taken; and, therefore, the affir-
mative evidence from the microscope, under these circumstances,
is as liable to lead to error as that which is purely negative. The
fact that spermatic stains are found on the linen of the prosecutrix
may, however, become occasionally of great importance in charges
of assault; as the following case (Reg. v. Hamilton), which was
tried at Edinburgh, Nov. 27th, 1843, will show. The prisoner,
who was at the time labouring under gonorrhoea, was charged
with a criminal assault upon a child. The shirt worn by the
prosecutrix, with other articles belonging to the prisoner, were
submitted to Mr. Goodair and Dr. Simpson for examination.
Some of the stains on the linen were of a yellow colour, and
were believed to be those of gonorrhoea; others, characterised by
a faint colour and a peculiar odour, were considered to be stains
caused by the spermatic secretion. Digested in water, they
yielded a turbid solution of a peculiar odour; and, when submitted to a powerful microscope, spermatozoa were detected. The majority of them were mutilated, the long slender filaments being broken off; but perfect specimens were seen, which differed from the living spermatozoa only in being motionless. The stains on the linen of the prisoner and the prosecutrix were similar. The prisoner was convicted of an assault with intent to ravish, and transported for fourteen years. (Cormack’s Edinburgh Journal, April, 1844.)

Analysis of stains.—There are no chemical tests on which we can safely rely for the detection of spermatic stains. The appearance produced by a dried spermatic stain on linen or cotton is very much like that produced by a diluted solution of albumen. The fibre of the stuff is stiffened, and the borders of the stain have a slight translucent appearance. It presents no well-marked colour. Slips of the stained linen, when soaked in a small quantity of distilled water, yield a mucous-albuminous liquid. It was long since noticed by Orfila that this liquid, unlike albumen, was rendered rather strongly yellow by diluted nitric acid. By the action of warm water, the stained linen, even although it may have been kept dry for a considerable period, has been observed to evolve the peculiarly faint odour of the spermatic secretion.

The microscopical detection of the zoospersms is attended with some difficulty, especially when the stained portion of linen has been much rubbed or worn. M. Donné states that he has not succeeded in discovering these bodies in dried stains (Cours de Microscopic, 304); but this must have been owing to the faulty methods of proceeding adopted by some of the French medical jurists. They have recommended that the stained linen should be soaked in so large a quantity of water as to require filtration; that it should be macerated for many hours; that warm water should be used; and that ammonia or some other chemical agent should be employed. These circumstances will account for the non-detection of zoospersms, since these minute fragile bodies are liable to be disintegrated and destroyed by such methods of research. The plan which I have found the most simple is that recommended by Dr. Koblanek, of Berlin. (Vierteljahrschrift für gerichtliche und öffentliche Medicin, 1853, 3d B. 1 Heft p. 140.) Cut out a portion of the stained linen. Pour on it in a watch-glass, or small porcelain capsule, eight or ten drops of distilled water (enough to allow of a general soaking or imbibition of the stained linen). There should be no surplus water in the capsule. After soaking for about ten minutes, press out the watery liquid with a glass rod, aided by the fingers. A portion of this liquid, examined microscopically, will, if the stain be of a spermatic nature, yield evidence of the presence of zoospersms. A high power of the microscope is required for this
experiment. A zoosperm is only indistinctly perceived by a most careful adjustment of the object glass under a power of 126 diameters. It becomes visible at 200 diameters; but here the tail and head may not be seen at the same time. Under a power of 340 diameters they are plainly visible. Dr. Koblanek employed 300 diameters, but used a second and more powerful instrument, to avoid the possibility of error.

The zoosperm has a flattened, oval, and perfectly transparent body, terminating in a filiform tapering tail, which, according to Curling, measure together 1-500th to 1-600th of an inch. I found that the oval body of one had a length of 1-6000th of an inch, and a width of 1-12000th. The tail was about five times the length of the body, and the whole length of the spermatozoon was equal to about the 1-1000th of an inch. These bodies are the chief characteristics of the healthy spermatic secretion; and, when discovered, they clearly indicate that the stains under examination must have been caused by the seminal fluid. They differ in size and shape in different species of mammalia; but there are none that precisely resemble those which are found in the human secretion. Donné thinks it possible that the fine fibres of linen or cotton, washed from the stained staff, might be mistaken for them. The microscopical characters of linen and cotton, however, ought to be sufficiently well known to an observer to prevent such a mistake from being made. Besides, medical evidence should be based on the undoubted detection of a perfect zoosperm. Minute fibres might be mistaken for the tails; and therefore it is desirable not to base an opinion on fragmentary evidence of this description.

Dr. Koblanek contends that, when they are not discovered by the process above described, it may be fairly asserted that the stains are not due to the spermatic secretion; but when the linen has been much rubbed, worn, or wetted by urine, blood, mucus, or pus, it will be a matter of considerable difficulty to discover these bodies, although there may really have been spermatic stains upon it. He has found that most of these foreign substances, however, may be removed by the addition of one or two drops of acetic acid, which exerts no dissolving action on the bodies of the zoosperms unless too concentrated.

As it has been elsewhere stated (ante, p. 667), these bodies, although peculiar to the seminal fluid, are not found in the very young, the very old, or in those who are labouring under long-standing disease of the testicles. In addition to the other facts mentioned respecting their characters, it may be remarked that they move for many hours out of the body when kept at a temperature of 98°, and even retain their rapid motions when the spermatic liquid is mixed with water; but these motions cease immediately on the addition of urine or chemical reagents. According to Müller, the zoosperms may retain vitality (or free
motion) in the body of a female for a period of seven or eight days, and even longer. When this vitality, indicated by free motion, has disappeared, the properties of the seminal fluid are destroyed, and there is reason to believe that it no longer possesses a fecundating power.

The detection of dead or motionless zoosperms in stains may be made at long periods after emission, when the fluid has been allowed to dry. Dr. Koblanek made experiments on this subject in reference to different periods of time. He found the zoosperms distinctly,—after three days; one month; three, four, six, nine, and even twelve months. The number of distinct and perfect bodies diminished according to the length of the period at which the examination was made. Thus, at the end of a year, only two perfect zoosperms could be perceived; but it may be stated, that the discovery of one distinct and entire body is quite sufficient to justify a medical opinion of the spermatic nature of the stain. M. Bayard states that he has been able to detect these zoosperms in stains after the long period of six years! (Man, Prat. de Méd. Lég. 277.)

Medical inferences.—A medical witness must be prepared to consider the precise value of evidence furnished by the microscope in the examination of stains on the dress of a man accused of rape. A shirt may present stains of urine, mucus, or gonorrheal discharge, some of which, but for the microscope, might be mistaken for spermatic stains. Admitting that, by the process above described, the microscope enables an examiner to affirm that the stains have really been caused by the spermatic secretion, this does not prove that a rape has been committed, or even that intercourse has been necessarily had with a female. Such stains may arise from spontaneous natural discharge, or from disease (spermatorrhoea), and therefore in themselves they afford no proof of intercourse. If from other circumstances in the case it should be clearly and satisfactorily proved that there has been intercourse, then the presence of blood mixed with the spermatic stains might, in certain cases, justify an opinion that violence had been used. The discovery of spermatic stains on the dress of a female furnishes stronger evidence of intercourse attempted or perpetrated, than their discovery on the dress of a male; but admitting that intercourse is proved, it may still have taken place with the consent of the female. These stains, when found on the dress of female infants, afford a strong corroborative proof of the perpetration of the crime.

Microscopical evidence from the female.—It may become necessary to determine, in reference to a female, whether intercourse has or has not recently taken place. All observers agree that, within a certain period after connection, the fact may be established by the examination of the vaginal mucous. A small quantity of this mucous, placed upon glass, and diluted with water, will be found to con-
tain zoospersms, if the suspicion be correct. M. Bayard states that
he has thus detected them in the vaginal mucus of females, subject
his various intervals up to three days after intercourse (op. cit. 277); and Donné found them under similar
circumstances in a female who had been admitted into the hospital the day before (op. cit. 305). This evidence may become
of value in a charge of rape; but it may be easily destroyed
by the presence of leucorrhoea: and it is open to an objection, that,
in certain morbid states of the vaginal mucus of the human female, there is found in it a microscopic animalcule, called by
Donné the *Trichomonas vaginae*. This has a larger body, and a
shorter tail, than the zoospersm; but the witness who trusts to
the use of the microscope on such occasions may be fairly asked,
whether he is able to distinguish the spermatozoa from the trichom-
nonades. They who are not used to microscopical investigations
may be easily deceived, especially when the spermatozoa are
dead and mutilated.

*Marks of blood.* — Marks of blood upon the linen can, of course,
not only no evidence unless taken with other circumstances. The
linen may be intentionally spotted or stained with blood for the
purpose of giving apparent support to a false accusation. Dr.
Bayard met with a case of this kind, in which a woman charged
a youth with having committed a rape upon her infant child.
On examination, the sexual organs were found uninjured; and
in a case of this kind, it was observed that the stains had been produced on the outside,
and bore the appearance of smearing. The whole fibre of the
stuff had not even been completely penetrated by the liquid.
These facts established the falsehood of the charge. (Ann. d’Hyg.,
1847, ii. 219.) It may be a question whether marks of blood on
the linen of the prosecutrix were caused by effusion as a result of
violence, or by menstrual discharge. The menstrual fluid in the
normal state is said to be entirely free from fibrin; but in respect
the red colour, the presence of red corpuscles and of serum,
the two kinds of blood are similar. That fibrin is frequently
present, and in large quantity, in the menstrual fluid, is obvious
from its being occasionally discharged in a clotted state: hence
the discovery of fibrin in a stain would not by no means necessarily
imply that the blood was from a wound, and not due to menstrual
discharge, while its non-discovery would not prove the blood to
be menstrual. Small quantities of fibrin are not readily separable
from linen stained by blood as a result of effusion; and suppos-
ing the stain to have been caused by imbibition from another
article of dress already stained, the secondary stain would be free
from fibrin, which would remain in the stuff originally wetted.
A man might thus wrongly pronounce this secondary stain to
be due to menstrual blood. The discovery of epithelial scales
and mucus, by the microscope, would not prove the stain to be
Evidence of violation in the dead. — Sometimes the body of a female is found dead, and a medical witness is required to determine whether her person has or has not been violated before death. There is here some difficulty, because there will be no statement from the prosecutrix herself. The witness can seldom do more than express a conjectural opinion, from the discovery of marks of violence on the person and about the genital organs. Even if spermatozoa were detected in the liquid of the vagina, or on the dress of a female, this would merely prove that there had been intercourse; whether violent or not, must depend on circumstantial evidence. In a case tried at Edinburgh some years ago, the first point to determine was, whether a rape had been committed. The examination of the stains on the dress was conclusive, taken in conjunction with some other pieces of circumstantial evidence. The jury convicted the man of the rape, and yet acquitted him of the murder, although the proof of the latter crime was clearer than that of the rape!

Legal relations. — The statute-law which refers to this crime is the 9 Geo. IV. c. xxxi. s. 17, 18. According to the eighteenth section, "Carnal knowledge shall be deemed complete upon proof of penetration only." The words are, perhaps, not sufficiently precise; for by one judge the law was thus interpreted: Carnal knowledge, i.e. penetration, is not complete, unless the hymen be ruptured. This, as it has been suggested, would divide penetration into vulval and vaginal; the former not constituting rape, but a common assault. The majority of the judges, however,
have not admitted a distinction of this kind. They have strictly adhered to the obvious and literal meaning of the words of the law, and have regarded the rupture of the hymen not as a necessary proof, but as strong evidence of penetration. The question of penetration is not for the medical witness, but for the jury to decide from the whole of the facts. In the case of a child, the prisoner was seen perpetrating the act; but it was proved that the hymen, which was normally placed, was not ruptured: yet this case was decided like that of Rex v. Russen: the crime was considered to be complete. Thus, then, when the material evidence of penetration (rupture of the hymen) is wanting, proofs may be derived from other and non-medical sources.

Rape by females on males.—So far as I can ascertain, this crime is unknown to the English law. Several cases of this kind have, however, come before the French Criminal Courts. In 1845, a female, aged 18, was charged with having been guilty of an act of indecency, with violence, on the person of Xavier T., a boy under the age of 15 years. She was found guilty, and condemned to ten years' imprisonment. In another case, which occurred in 1842, a girl, aged 18, was charged with rape on two children, the one 11, and the other 13 years of age. It appeared in evidence that the accused enticed the two boys into a field, and there had forcible connection with them. This female was proved to have had a preternatural contraction of the vagina, which prevented intercourse with adult males. She was found to be labouring under syphilitic disease; and the proof of her offence was completed by the disease having been communicated to the two boys. She was condemned by the Court of Assizes of the Seine, to fifteen years' hard labour at the galleys. (Ann. d'Hyg. 1847, i. 463.) By the penal code of France, it is a crime in either sex to attempt intercourse with the other, whether with or without violence, when the child is under eleven years of age. That this offence is perpetrated in England cannot be doubted. It is by no means unusual to find, in the wards of hospitals, mere boys affected with the venereal disease. In some instances this may be due to precocious puberty; but, in others, it can only be ascribed to that unnatural connection of adult females with male children, which is punished as a crime in the other sex. The only accessible medical proof would consist in the transmission of gonorrhoea or syphilis from the woman to the child.

SODOMY. BESTIALITY.

This crime is defined, the unnatural connection of a man with mankind or with an animal. The evidence required to establish it is the same as in rape, and therefore penetration alone is sufficient to constitute it. There are, however, two exceptions: it is not necessary to prove the offence to have been committed against
the consent of the person upon whom it was perpetrated; and
2ndly, both agent and patient (if consenting) are equally guilty;
but the guilty associate is a competent witness. In one case (Rev
v. Wiseman), a man was indicted for having committed this offence
with a woman, and a majority of the judges held that this was
within the statute. Unless the individual be in a state of insens-
sibility, it is not possible to conceive that this offence should be
perpetrated on an adult of either sex against the will of a person.
The slightest resistance will suffice to prevent its perpetration.
In August 1849, a question on this point was referred to me from
Kingston, Jamaica. A man was convicted, and sentenced to
transportation for life, for the crime of sodomy, alleged to have
been committed on the complaining party while he was asleep.
The only evidence against him was the statement of the com-
plainant. The opinion given was in conformity with that of
Dr. J. Ferguson, who referred the case to me, namely, that the
perpetration of the act during a state of natural sleep was con-
trary to all probability. If the crime be committed on a boy
under fourteen years, it is felony in the agent only; and the
same, it appears, as to a girl under twelve. (Archbold, 409.)
The act must be in the part where it is usually committed in the
victim or associate of the crime, and if done elsewhere it is not
sodomy.

The facts are commonly sufficiently proved without medical
evidence, except in the cases of young persons, when marks of
physical violence will in general be sufficiently apparent. In
some instances, proof of the perpetration of the crime may be
obtained by resorting to microscopical evidence. (See Donné,
op. cit. 305.) Stains upon the linen of young persons may thus
furnish evidence that the crime has been attempted, if not actually
perpetrated. Trials for this crime are very frequent, although
it was not, like rape, specially excepted from capital punishment
by the 4th and 5th Vict. cap. 111. It is also said to be on the
increase. (Law Times, Jan. 4th, 1845.) There cannot be the
slightest doubt that false charges of this crime are more numerous
than those of rape, and that this is too often a very successful
mode of extortion. This is rather a legal than a medical ques-
tion; but it is especially deserving of notice, that these accusa-
tions are very frequently made by soldiers and a bad class of
policemen.
ASPHYXIA.

DROWNING.

CHAPTER LVII.

The cause of death. Apnœa.—Asphyxia.—Many opinions have been entertained respecting the manner in which death takes place by drowning. It was at one time supposed that the water which passed into the stomach of a drowning animal had an injurious effect, and operated as the immediate cause of death. This opinion prevailed before the importance of the respiratory process in the economy was fully understood. It would, however, have been easy to show the insufficiency of this explanation by a simple appeal to facts. Water is not invariably found in the stomachs of the drowned; and, again, it may be introduced into the stomach in much larger quantity than we are accustomed to meet with it in the body of a drowned person, without producing any deleterious effect. The presence of water in the bronchial ramifications of the lungs has been suggested as a probable cause of death: it was thought that it operated here by arresting the circulation of blood in the minute pulmonary vessels. This explanation of the cause of death in
drowning would imply that water was always present in the lungs of the drowned, which, however, is not the case; and, indeed, when found, it is often met with in small and variable quantity: facts which sufficiently show that this hypothesis cannot be entertained. The spasmodic closure of the glottis during the act of drowning, tends greatly to prevent the entrance of water into the wind-pipe. Death has also been attributed to collapse of the lungs, by which the blood is presumed to be mechanically prevented from traversing the pulmonary structure. It is a generally admitted fact that a considerable quantity of air is, in most cases, expelled from the lungs during the act of drowning, but these organs are not commonly found collapsed in drowned animals; and when this condition is observed, it is rather to be regarded as a consequence, than a cause, of death.

No doubt now exists among physiologists that death by drowning is due to apnea (from a priv. and λυω I resipe) or suffocation, in which condition breathing is arrested, and the blood is at first circulated in a state unfitted to support animal life, and sooner or later its circulation through the minute vessels of the lungs is wholly arrested; then producing the state of asphyxia (from a priv. and σφυείς pulse). According to some authorities, however, apnea and asphyxia express the same condition, i.e., the state of lifelessness induced by the stoppage of respiration, while others consider apnea to be the first stage of asphyxia. To the arrest of the pulmonary circulation as a consequence of the suspension of breathing, must be ascribed the gorged or congested condition of the right cavities of the heart as well as of the lungs of the drowned, which is frequently observed in death from asphyxia. The observations of Sir B. Brodie (Lectures on Pathology, 66) and others clearly prove that the circulation may be carried on for two or three minutes, or even longer after respiration has ceased, so that there is not a sudden cessation of the heart’s action. Asphyxia is induced in drowning owing to a physical impediment to the introduction of air into the lungs; and we have, therefore, in this form of death, a simple illustration of that state. The medium in which the individual is immersed acts mechanically and as effectually as a rope or ligature around the neck; for although air escapes from the lungs, and water may penetrate into the minute air-tubes, yet no air can enter to supply the place of that which has already expended a certain quantity of its oxygen on the blood. Hence this fluid must circulate in the first few minutes after submersion in a state unfitted for the support of existence (un-aerated); but the individual lives and is susceptible of recovery so long as this circulation continues. After the entire suspension of respiration, the action of the heart gradually slackens, and finally stops. It is at this period of the complete arrest of circulation that asphyxia passes into death. Apnea is deter-
DROWNING. SYMPTOMS PRECEDING DEATH.

When a person falls into water, and is exposed to this kind of death, vain attempts are made to expire: at each time that he rises to the surface a portion of air is received into the lungs, but owing to the mouth being on a level with the liquid, water also enters and passes into the fauces. A large quantity of water thus usually passes into the mouth, which the individual feels himself irresistibly compelled to swallow. The struggle for life may continue for a longer or shorter period, according to the age, sex, and strength of the person; but the result is, that the blood in the lungs is imperfectly aërated, and the individual becomes exhausted. The mouth then sinks altogether below the level of the water, and no longer enter into the lungs,—a portion of that which they contain is expelled, and rises in bubbles to the surface: an indescribable feeling of delirium, with a ringing sensation in the ears, supervenes,—the person then loses all consciousness, and sinks asphyxiated. Before death, and while the body is submerged, frequent attempts are made to breathe, but at each effort air escapes from the lungs, so that these organs may, according to the duration of the struggle, become more or less emptied, and even be found collapsed after death. During the state of asphyxia dark-coloured blood is circulated,—convulsive motions of the body follow, and the contents of the stomach are sometimes ejected prior to dissolution. There is not the least sensation of pain, and, as in other cases of asphyxia, there is a total unconsciousness of suffering during the period when the access of air is cut off from the lungs. I state this from having accidentally experienced all the phenomena of drowning up to the complete loss of sensibility and consciousness. (See, in reference to the phenomena of asphyxia from drowning, a paper by Mr. Eccles, Med. Gaz. Vol. xlv, page 657.)

Some persons who fall into water are observed to sink at once without making any attempt to extricate themselves. This may arise from the stunning produced by the fall; and if the fall take place from a great height, the effect is probably aided by the forcible compression which the thorax then sustains, whereby the lungs are in great part emptied. Should the person be intoxicated or otherwise incapacitated, as by striking his head in falling, he may not again rise. These different conditions under which death may take place will sufficiently account for the great difference in the appearances met with in the bodies of those who have died under these circumstances. Some medical
DEATH NOT CAUSED BY APOPLEXY.

jurists have considered that they who are submerged while living, frequently perish by syncope, and in other instances by what has been termed syncopal asphyxia—a mixed condition. It has been supposed that the state of terror into which a person may be thrown prior to submersion, would be sufficient to bring on syncope; and this, it was presumed, offered an adequate explanation of the recovery of the apparently drowned, when the body had remained a long time in water. It may readily be admitted that in some instances the mental shock may be so great to a person falling into water, as to induce syncope, especially in females; but the occurrence of this state appears to be founded rather upon presumption than upon actual observation.

Death not caused by Apoplexy.—Some have ascribed death in drowning to a congested state of the cerebral vessels,—in other words, they conceive that death takes place in most cases by a species of apoplexy. That a congested state of the cerebral vessels is often met with in the bodies of the drowned, is a fact which cannot be disputed; but the same degree of congestion is observed, not only in other cases of asphyxia, but also in the inspection of bodies when death has proceeded from various causes unconnected with cerebral disturbance. There is no ground, therefore, for attributing death to an apoplectic attack;—a mere fulness of the cerebral vessels is certainly of itself insufficient to justify this view, for upon the same evidence we might pronounce three-fourths of those deaths which are distinctly referable to other causes, to be dependent on apoplexy. The obstruction to the passage of the blood through the lungs is sufficient to explain why we meet with a sanguineous congestion in the cerebral vessels of drowned subjects; and there is great reason to believe that the occurrence of this congestion is posterior to the interruption of the cerebral functions. The most characteristic appearance of apoplexy—effusion of blood on the brain—is rarely seen in the drowned; and probably, when it exists, it might be traced to mechanical violence before submersion, or to the head having come in contact with hard bodies beneath the water. I have met with three instances in which extravasation of blood on the brain was found:—the one was in the case of Leopold, Duke of Brunswick, who was drowned in the Oder during the German war (see Henke, Gericht. Med. 327); the second was in a case which occurred in London in 1839; and the third is reported by Casper. A man was drowned in a marsh. There were the usual appearances in the body. The membranes of the brain were strongly congested, and blood was effused to the extent of an inch beneath the outer membrane (dura mater). In general, the term apoplexy is applied to those cases of drowning in which there is great fulness of the cerebral vessels; but, in most of
these, there are also signs of death from asphyxia. (Ger. Leich-Oeffn., ii. p. 110.)

Mixed cases.—It is obvious that they who die from apoplexy, concussion, or syncope, at or about the time they fall into water, cannot be said to die from drowning. An individual so situated makes no effort to respire, and it is only by interfering with respiration that water operates. Admitting, then, that in strictness asphyxia is the sole cause of death in drowning, these mixed cases are of interest in medical jurisprudence only because the apparent may be mistaken for the real cause. It may be occasionally necessary to determine whether the person really died by drowning or not, i.e. whether he was asphyxiated by water or not; since an answer to this question may materially affect the position of a prisoner charged with homicide. The only conclusion at which we can arrive is, that many persons may fall into water, and appear to be drowned, whose deaths have actually preceded their submersion. They may have died from fright or terror at their situation, or have been killed by their heads coming accidentally in contact with hard bodies during the fall, or even with the surface of water itself; for this may be sometimes sufficiently resisting to produce concussion of the brain, when the fall is from a great height, and the head comes first in contact with the water. It is probable that some also perish owing to a shock received at the pit of the stomach by the violence of the fall. A shock thus received in the region of the heart might possibly suspend the functions of that organ, and kill the person by inducing sudden syncope. A case is mentioned in the Dublin Medical Journal for May 1837, which appears to bear out this view. Again, there may be extensive but latent disease of the heart which may fully account for sudden death irrespective of submersion. (See case in Lancet, Nov. 16, 1850, p. 550.)

Death from secondary causes.—Drowning may operate indirectly as the cause of death. Thus it has been repeatedly remarked that persons who have been rescued from water in a living state, have died, in spite of the application of the usual restoratives, after the lapse of some minutes or hours; others have lingered for one or two days, and then have sunk apparently from exhaustion. In those who perish soon after removal from the water, death may arise from the exhaustion produced by the struggles of the individual for life, aided by the long contact of the body with a cold medium. In the case of Mr. Gudge (May 1857) death was owing to the secondary effects of submersion. The deceased was removed from the water and conveyed to the Westminster Hospital. He was cold and insensible, but he breathed tolerably well and had a fair pulse. In about three yours, he became conscious and spoke a little. The insensibility subsequently returned accompanied by great difficulty of breathing, and he died in about twenty hours from the time of sub-
mersion. Dr. Marjet states that spasm of the glottis has been among the severe secondary symptoms in those who have been removed from water apparently drowned. A severe spasm of this kind manifested itself in one case while placing the person in a warm bath. (Med. Times and Gazette, Feb. 7, 1857, 148.)

When death occurs at a remote period, it may be due to disease; and the question will then be, whether the disease was produced by the immersion in water or not. Such cases occasionally present themselves before our Courts of Assize. In one of these (Reg. v. Pulham, Gloucester Summer Assizes, 1845), the prisoner was charged with the death of deceased by pushing him into a pond of water, from the effects of which he died. The deceased was an old man; he was taken out of the water in a very exhausted condition, and died a few weeks afterwards. One medical witness referred death to the effects of the immersion; but as he had not attended the deceased after the violence, and there was no clear account of the cause of death, the prisoner was acquitted. In most of these cases it will be found exceedingly difficult to connect death with the immersion, when the fatal result does not take place until after so long a period of time. We must on such occasions rely upon the nature of the disease alleged to have been caused by immersion, e.g. inflammation of some cavity or organ, and its progress until death without intermediate recovery or interference by improper treatment, as the basis of our evidence.

According to M. Devergie (Méd. Lég. ii. 336), of one hundred individuals who fall into the water, or are exposed to the chances of drowning, the following may be taken as the numerical ratio of the causes of death:

<table>
<thead>
<tr>
<th>Cause</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Asphyxia pure</td>
<td>25.0</td>
</tr>
<tr>
<td>and Syncope</td>
<td>62.5</td>
</tr>
<tr>
<td>Cerebral Congestion</td>
<td>87.5</td>
</tr>
<tr>
<td>Syncope, Apoplexy, or Concussion</td>
<td>12.5</td>
</tr>
</tbody>
</table>

Total: 100.0

From this table we learn that out of one hundred bodies removed dead from water, where death was due either directly or indirectly to immersion,—if the body were removed immediately after death, and examined soon after removal, the signs of drowning would be present in about 25;—they would be imperfectly apparent (asphyxia more or less marked) in about 62, and they would be wholly absent in about 12. This table may not represent the actual truth, but as the medical jurists of Paris have ample opportunities of examining the drowned, it is probably as near an approximation as the present state of science will permit us to reach. (For a full examination of the causes of death in
drowning, by Dr. Loeffler, see Henke, Zeitschrift der S. A. 1844, i. 1.)

Period at which death takes place.—A witness may be asked how long a time is required for death to take place by drowning. In giving an answer to this question, it must be remembered that all who fall into water and are exposed to the risk of drowning, do not really die by this kind of death. Thus all cases of death from syncope or apoplexy must be excluded from our consideration. In these, circulation and respiration are simultaneously arrested. Some persons who are strong, who are good swimmers, and retain their presence of mind, may support themselves for a length of time in water, while others who are weak and delicate may struggle only for a few seconds, and then sink exhausted and lifeless. There are two very different points involved in this inquiry:—1. How long can a person remain beneath the surface of water without becoming asphyxiated (drowned ?) and 2. After what period of entire submersion of the body may we hope to resuscitate a person? In regard to the first point, it may be remarked, that when the mouth is so covered that air cannot enter, asphyxia supervenes in the course of one or two minutes at the farthest, and the time at which this occurs does not appear to vary materially with the individual. It has been observed that perfect insensibility has supervened after a minute's submersion, and it is probable that in most cases a few moments would suffice for the commencement of asphyxia. In the case of a healthy diver who was accidentally submersed, at Spithead, in July, 1842, for a minute and a half without the power of breathing, at the depth of eighty feet, it was observed that when drawn up he was faint but sensible. (Med. Gaz. xxxi. 90.) Observations made upon sponge and pearl-divers show how short a period a human being, even when practised in the art of diving, can continue without breathing. Dr. Lefevre, of Rochefort, found that among the Navarino sponge-divers, accustomed as they were to the practice of diving, there was not one who could sustain entire submersion of the body for two consecutive minutes. The average period of entire submersion was seventy-six seconds. (Med. Gaz. xvi. 608.) According to Mr. Marshall, the best pearl-divers of Ceylon could rarely sustain a submersion of more than fifty seconds. Thus, then, it would appear from these and other observations, that asphyxia is probably induced in most individuals in the course of a few seconds, and that at the farthest it occurs in from a minute to a minute and a half. But asphyxia is not synonymous with death, and while in most persons asphyxia may commence at or about the same period of time, there are probably very few in whom, under complete submersion, the circulation would be arrested or death take place at precisely the same instant of time. Such a simultaneous arrest of the action of the heart in two persons must be the result of a pure coinci-
DROWNING. PERIOD FOR RESUSCITATION.

Dence. This medical question may be occasionally of importance in reference to the presumption of survivorship, as when husband, wife, and children have died from drowning under a common calamity.

Period for resuscitation.—The second point to be considered is — how long a period of entire submersion is required for death to take place, i. e. when is there no further hope of resuscitating a drowned person? This question is of great importance in relation to the treatment of the drowned. The insensibility which is the result of submersion will give to a body which has been immersed only a few minutes, or even seconds, the characters of apparent death; but we are not therefore to suppose that the person is irrecoverably lost, or to desist from applying all the means in our power to restore animation. On the contrary, it is only a proper act of humanity that the means should be applied without delay, even to bodies which have remained so long in water as to afford, physiologically speaking, but little hope of ultimate resuscitation. A man who would neglect the application of these, would consign the body to certain death; while, by adopting an opposite course, he might, perhaps, unexpectedly to himself, succeed in restoring a fellow-creature to existence. Hence we are not to allow ourselves to be influenced, in the treatment of the drowned, by the shortness of the period at which death most commonly takes place; for it is possible that two individuals may be drowned under the same circumstances, and treated, on removal from water, in the same way; yet the means of resuscitation will be effectual in one case, while they may totally fail in the other. It ought to be borne in mind that the period of death, and the susceptibility to the restoration of life, may be very different in the two subjects: were this not the case, it would be impossible to explain why, under the most judicious treatment, every effort will fail in restoring animation in a subject which has been submerged only two minutes, while the same means will perfectly succeed in resuscitating another subject which may have been submerged five or even ten minutes. Devergie states that it has been found impossible to restore some who had not been entirely submerged for more than a minute, and when the bodies were removed with all the warmth and pliancy of life about them: but, on the other hand, others have been resuscitated who, there was reason to believe, had been entirely submerged for five minutes. It is necessary that these circumstances should be clearly explained; for many of the marvellous recoveries reported, have no doubt been cases of the resuscitation of individuals who had not been entirely submerged, i.e. with the head entirely below water, for the period alleged. If we are called upon to state, physiologically, how we can reconcile the accounts of resuscitation after the body has remained for a quarter of an hour or even for a longer period in water with the fact of
the general occurrence of death within the short interval of a few
seconds or minutes from the time of submersion, we must look
upon such accounts, provided their authenticity be placed beyond
all doubt, as extraordinary exceptions to a very widely-extended
rule. It is necessary to observe that the head of the subject may
not have been under water during the whole of this time: the
individual may have struggled long, and have risen frequently to
the surface, or the upper part of his body may have received
support from some mechanical obstacle. All these circumstances,
as well as the depth of the water in which the body is found,
should be duly considered before we proceed to admit statements
which are opposed to facts well established by experiment and
observation. In most of the cases on record, the evidence has
been derived from ill-informed and ignorant persons, who were
but little fitted to convey accurate information upon so important
a question, and whose opinions we should be extremely cautious
in receiving. Besides, the period of submersion has been stated
upon conjecture, not upon actual observation of the time.

Recovery after submersion for long periods.—The following facts
may, it appears to me, be relied on, in relation to this question.
Dr. Woolley, formerly an active medical assistant of the Royal
Humane Society, met with one case in the Records of the
Society, in which the individual was resuscitated after five minutes'
submersion (Lancet, Oct. 1841). He informs me that another
has since occurred. In the Report of the R. H. Society for 1840
there were two cases of successful resuscitation after one minute
and a half,—and two cases after three entire minutes' submersion.
In a case communicated to me by Mr. Bloomfield, in 1841, a boy
recovered after a submersion of from five to ten minutes. In
another, communicated to the Lancet by Mr. Smethurst (July
1841), a girl aged two years recovered after ten minutes' immer-
sion:—it is not quite certain whether, in this instance, the head
was under water during the whole of this time. A case of
recovery after six minutes' alleged submersion will be found in
the Med. Gaz. (xxix. 78): and in a case communicated to the
Medical Times (Dec. 2, 1848, p. 125), by Dr. Octavian Royle, it
was inferred that there was partial recovery after a submersion
of at least eight, and probably thirteen minutes. In Vol. xxxi.
p. 448, of the Med. Gaz., is perhaps one of the most remarkable
of these cases, in which an individual is stated to have been
resuscitated after fourteen minutes' submersion; and the case
carries with it great probability, although the time was derived
rather as a matter of calculation from circumstances than from
actual observation. Mr. Jennings has reported a case in which
by prompt treatment a female recovered after twenty minutes'
This is the longest authentic period with which I have been able
to meet. Cases of alleged recovery after half an hour and even
TREATMENT OF THE RECENTLY DROWNED.

three quarters of an hour will be found reported; some have endeavoured to explain these by assuming that the individuals in question were restored from a form of syncope which had occurred in consequence of the mental shock experienced at the moment of submersion. It has been admitted that syncope may occur under these circumstances, and it is possible also that the susceptibility of resuscitation may remain longer in a subject labouring under syncope, than in one who has perished by asphyxia: but the question here obviously presents itself, whether the lungs can cease to act, and the heart to circulate blood, for the period of half an hour, consistently with the maintenance of life. The medical jurist must remember, that respiration cannot possibly continue when the body remains entirely submerged; for it is impossible that air can enter into the lungs, and although, provided syncope be not previously induced, the circulation does continue, it is not, generally speaking, maintained above three or four minutes in a person so situated. There are few, indeed, who would be disposed to admit that respiration and circulation could remain so long entirely suspended in any individual whether he be in a state of syncope or asphyxia, without the complete destruction of life; or if they did admit the possible occurrence of so great a deviation from the common phenomena of vitality, they would require better evidence for such an admission than that by which these cases are usually supported. It is probable that in these instances of protracted asphyxia, in which persons have recovered, some slight action of the heart has still continued. In experiments on drowned animals I have never found that life could be restored after the animal had remained entirely submerged for the space of four minutes. In one case, in which a stout healthy man had been submerged five minutes, and every means for resuscitation speedily used, the result was unfavourable. We are, then, bound unhesitatingly to declare that in drowning, life is very speedily destroyed,—that the time within which resuscitation may be successfully attempted is subject to variation,—and lastly, that the cases which have been hitherto recorded of restoration after lengthened submersion of half an hour and upwards, are to be regarded as extravagant fables. I am glad to be supported in these views by the observations of so experienced a writer as Sir B. Brodie. (Lectures on Pathology, 90.)

**Treatment.**—A question has often arisen at coroners' inquests, whether death may not have been really due to neglect in the treatment. The principles to be observed are, 1. To wipe the body dry. 2. To keep the head and shoulders raised. 3. To restore the warmth of the body. This may be done, according to the means at hand, by warm blankets, bottles or bladders of hot water, bags of hot sand or salt, hot bricks, the warm-water-bath (at 100°F.), or the warm-air-bath. (For an account of the
latter, see Med. Gaz. Sept. 1838.) A heated covered warming-pen may be passed over the abdomen and back. The warmth should be especially applied to the feet and abdomen. The body may be fomented with hot flannels, and the surface rubbed briskly with the hand. 4. The cautious application of stimulants, such as snuff or diluted ammonia, to the nostrils. 5. Having cleared the mouth and fauces, we should move the chest, in order to simulate the act of respiration. 6. The employment of stimulating embrocations, such as the Compound Camphor Liniment rubbed by a warm flannel on the trunk and limbs. It is not advisable to employ venesection until signs of recovery appear, nor even then unless this treatment should be indicated by great cerebral congestion. Much difference of opinion exists on the propriety of introducing air into the lungs by artificial processes. Dr. Woolley, who has had considerable experience in the treatment of the drowned, denies its efficacy (Med. Gaz. xvii. 663), and states that in the cases in which he had been successful in resuscitating them, he had not inflated the lungs. This is certainly strong evidence against the alleged necessity for the practice, and it is corroborated by the observation of Dr. Douglass (Med. Gaz. xxxi. 449), in one of the most remarkable cases of resuscitation on record; for the individual here had been fourteen minutes under water, and no signs of returning animation were evinced, until the treatment—which consisted simply in the application of warmth, and constant friction—had been persisted in for eight hours and a half from the time of the accident. Inflation of the lungs was tried, but not continued, as, while it did not appear to be attended with any good effect, it interfered with the frictions on which the greatest dependence was placed. Dr. Woolley informs me, as the general result of his experience on the restoration of the drowned, that the warm bath at 100°, with friction, has always afforded the best chance of recovery, and when some signs of animation were not elicited by the use of the bath, there was very little hope of any other plan succeeding.

The experience of Dr. Woolley, regarding the inefficacy of artificially inflating the lungs, has been confirmed by the observations of the late Dr. Marshall Hall. This physiologist advises that respiration should be imitated, not by moving the chest, as in rule 5, but by moving the body. I subjoin Dr. Hall's suggestions for the treatment of the drowned. It will be perceived that he is adverse to the use of the warm bath, which was found so efficacious in the hands of Dr. Woolley. Dr. Hall's mode of treatment is stated to have been found effectual in cases in which it has been tried; but further experience is required in order to determine whether it should entirely supersede the other plans recommended. According to Dr. Hall, the duration of life in asphyxia, is proportionate, not to
the warmth, but to the maintenance of a medium temperature of the patient or animal that is made the subject of experiment. The restoration of warmth can only be safely effected when respiratory movements are maintained and the circulation is promoted.

1. Treat the patient instantly, on the spot, in the open air, exposing the face and chest to the breeze (except in severe weather). I. To clear the throat.—2. Place the patient gently on the face with one wrist under the forehead [all fluids and the tongue itself then fall forwards, leaving the entrance into the windpipe free.] If there be breathing wait and watch; if not, or if it fail—II. To excite respiration.—3. Turn the patient well and instantly on his side, and 4. Excite the nostrils with snuff, or the throat with a feather, &c., and dash cold water on the face previously rubbed warm. If there be no success, lose not a moment, but instantly—III. To imitate respiration.—5. Replace the patient on his face, raising and supporting the chest well on a folded coat, or other article of dress. 6. Turn the body very gently on the side, and a little beyond, and then briskly on the face, alternately, repeating these measures, deliberately, efficiently, and perseveringly fifteen times in the minute, occasionally varying the side [when the patient reposes on the chest, this cavity is compressed by the weight of the body, and expiration takes place; when he is turned on the side, this pressure is removed, and inspiration occurs]. 7. When the prone position is resumed, make equal but efficient pressure, with brisk movement, along the back of the chest, removing it immediately before rotation on the side [the first measure augments the expiration, the second commences inspiration]. The result is—respiration, and, if not too late, life. IV. To induce circulation and warmth—8. Meantime rub the limbs upwards, with firm grasping pressure and with energy, using handkerchiefs, &c. [by this measure the blood is propelled along the veins towards the heart]. 9. Let the limbs be thus warmed and dried, and then clothed, the bystanders supplying the requisite garments. 10. Avoid the continuous warm bath, and the position on or inclined to the back. (Med. Times and Gaz. June 13, 1857, p. 609.)

Although a person may have been only one minute submerged, if much time has elapsed before the means for resuscitation are employed, there can be no hope of success. It has been stated that, after ten or fifteen minutes' submersion, there is but little hope of recovery; yet these attempts at restoring animation often fail from the delay which ensues in commencing the treatments. In this respect, Dr. Marshall Hall's plan has the advantage of all others: hence it has been called the "ready method." Thus there will be a better chance of recovering one who has been five minutes submerged, where the
treatment is immediate, than another who may have been only two minutes submerged, but where a delay of from ten to fifteen minutes has occurred in the application of the means. This obstacle to recovery is often overlooked—attention being paid to the period of submersion only. On these occasions we should not be justified in declining to employ the means of resuscitation, merely because the body was cold and apparently lifeless. Another point to be considered is, for how long a period should the efforts at restoration be continued. When the treatment is commenced under circumstances which justify a fair hope of success, it would be proper to continue it for at least an hour. In a case which occurred to Mr. Bloomfield, an hour and a half elapsed before there were any signs of returning animation. In Dr. Douglass's case, resuscitation began to be only feebly established after eight hours and a half spent in the treatment! (ante, p. 730.) There is no doubt that this case would have been abandoned as hopeless by many, long before this period, especially as the man had been submerged fourteen minutes: and thus, perhaps, many persons are lost, who might be recovered by perseverance. The tendency to restoration is often evinced by the occurrence of a slight lividity in the face, with convulsive twitchings in the facial muscles; and before recovery takes place there are sometimes convulsive movements of the limbs and trunk. In Paris, from 1821 to 1826, out of five hundred and seventy-six cases of drowning, four hundred and thirty were resuscitated.

Appearances after death.—In conducting the examination of the body of a drowned person, it is necessary to remember that the external and internal appearances will vary much, according to the length of time during which the body may have remained in the water, or the period that may have elapsed after its removal and before it is examined. Two subjects may be taken out of water at the same time—one may be examined immediately, while the examination of the other may be deferred for several days. In these cases the appearances after death will be no longer similar; and the differences will be particularly great, when the last-mentioned body has been exposed to a high temperature and to the free access of air.

1. External Appearances.—Supposing that the body has remained in the water only a few hours after death, and the inspection has taken place immediately on its removal, the skin will be found cold and pallid—sometimes contracted, under the form of cutis anserina. (Ed. Med. and Surg. Jour. Jan., 1837.) This contracted state of the skin furnishes strong evidence of the body having gone into the water living. (See post, p. 741.) The skin is often covered to a greater or less extent by livid discolorations. The face is pale and calm, with a placid expression, the eyes are half-open, the eyelids livid, and the pupils dilated; the mouth
closed or half-open, the tongue swollen and congested, frequently pushed forwards to the internal edges of the lips, sometimes indented or even lacerated by the teeth; and the lips, together with the nostrils, covered by a mucous froth which oozes from them. A singular external appearance has been noticed by Kanzler in reference to the male subject — namely a remarkable retraction of the penis. In men who have gone living into the water and been drowned, this appearance has been observed by Casper and Kanzler; and the former states that he has not met with this condition of the male organ after any other form of death. In strong and robust men, the organ has been found very short, and strongly retracted into the skin. (Gér. Leich.-Öffn. ii. 109.)

Rigidity and spasm. — The body may be found rigid, and the hands clenched. An important question arose in the case of the Queen v. George (Hereford Lent Assizes, 1847), namely, whether drowning was likely to produce a convulsed or contracted state of the limbs. The prisoner was indicted for the murder of her infant child, by drowning it. When taken from the water (in the month of December), about nine days after the supposed murder, there were no marks of external violence. The arms and legs were contracted, and the hands closed. On inspection, the vessels of the brain were congested, the lungs were collapsed, and there was farinaceous food in the stomach, partially digested. The state of the trachea, and the presence or absence of mucous froth, are not referred to. It will be seen from this description, that there was no appearance to indicate death from drowning with any certainty, and the medical witness admitted, that but for the discovery of the body in water, a suspicion of death from drowning would not have been entertained. From the state of the brain, death might have been referred to convulsions. The defence was, that the child had probably died of convulsions, and that, in order to dispose of the body, the prisoner had stripped it of its clothes, and thrown it into the water after death. The medical evidence failed to show that the child had died from drowning, and the prisoner was acquitted. The contracted state of the child’s limbs appears to have created a difficulty in the defence. The clothes of the child were neither cut nor torn, and the medical witness considered that had the limbs been as contracted as they were when the body was found, they could not have been removed without cutting or tearing. The medical question therefore was, whether the state of the child’s limbs did not prove that it had been put into the water while living. As the usual appearances of death from asphyxia were entirely wanting, it is proper to consider whether there may not be some explanation of the facts consistently with death before immersion. The admission made by the witness in cross-examination, appears to supply all that is necessary for this explanation. If the child
had died of convulsions, if the clothes were then removed, and
the body thrown in immediately, the sudden effect of the cold
water might have occasioned the contraction of the limbs; or
the child may not have been really, but only apparently dead,
when the mother stripped it. If some time had elapsed before
immersion, so that the body had become cold, then the limbs
would have been found either relaxed, or stiffened in a straight
position. The persistence of this contracted state for so many
days, may be explained by the immersion having taken place at
the coldest season of the year.

In general, when the dead bodies of the drowned are taken
from water, the limbs are found relaxed; but this must depend
on the period at which they are removed. Convulsions are
known to precede death by asphyxia, but the effects of these
on the body are generally lost when the person dies. Rigidity
of the muscles takes place after death in water, perhaps more
rapidly than in air. If the water be intensely cold, and the
individual have struggled violently, the last struggles of life may
be indicated by the contorted state of the limbs persisting
through rigidity. Mr. Beardsley, a former pupil, has commu-
nicated to me the following case which he had to examine. A
young man, while skating, fell through the ice of a pond about
seven yards deep. This was in February 1847. He was not
totally immersed, for he kept his head and shoulders out of
the water above the ice, with his arms resting upon it; and
as the ice gave way under his weight, he sprang on to a fresh
portion. Before assistance could be rendered, he sank to the
bottom. The body was removed the next day; it was found
at the bottom of the pond, beneath the hole in the ice. The
arms of the deceased were quite stiff, and still retained the
position in which he had rested upon the ice; his legs were quite
extended, and the muscles on the fore part of the thigh were
very much contracted, as if they had been powerfully exerted
in keeping him erect while he was hanging on the ice. There
was no appearance of his having attempted to breathe after he
had gone below the water. His countenance was quite natural—
there was no water or froth in his mouth; and in Mr. Beardsley's
opinion, the subject had the appearance of a body immersed
after death from some other cause. There was no internal in-
spection. Mr. Beardsley's opinion was, that the water being
about 32°, the man was in reality killed by cold, or frozen; and
there is no doubt, that if this did not operate as the direct cause
of death, it materially accelerated it.

This case is of interest in reference to a point to be presently
adverted to; namely, the fact of drowned persons being often
discovered with substances firmly grasped in their hands. A
contracted state of the muscles at the time of death may pass
into perfect rigidity by the effect of cold water; and thus the
attitude, or the last act of life of the individual, may be preserved. It is precisely analogous to what has been called cadaveric spasm.

Changes produced by putrefaction.—If the body has been submerged for a long period, or has remained long exposed before inspection, the skin will be found variously discoloured, according to the degree to which putrefaction may have advanced. If three or four months have elapsed before its removal from water, the skin covering the legs may be, in the first instance, of a deep blue colour: but when the body is exposed to air, this colour gradually disappears, and the skin becomes of a dirty brown with a tinge of green. The influence of air upon the skin of a drowned subject is most remarkable in the face and thorax. When the body has remained for some days in water, and has been exposed for a few hours only after its removal, the temperature of the atmosphere being moderately high, the face will commonly be found livid and bloated, and the features so distorted that they will be with difficulty recognised. The change chiefly consists in the skin becoming at first of a livid brown colour, which gradually passes into a deep green. That these effects are to be ascribed to the free contact of air, appears evident, from the fact that they are most fully developed in those parts of the body which are the most exposed to the atmosphere. Thus, the changes of colour in the skin are not commonly met with where any parts of the cutaneous surface have been in close contact, as in the armpits and inner surfaces of the upper and lower extremities, where the former have been closely applied to the sides of the trunk, and the latter have remained in close proximity to each other. For the same reason, the discoloration is not commonly observed at the back of a subject, or in those parts where the body has been closely wrapped in clothes.

The changes from putrefaction, even when these are comparatively slight, may, as Casper justly remarks, seriously affect the value of medical evidence. The blood becomes decomposed, acquires a darker colour, and produces congestions in the brain, lungs, right side of the heart, and other parts of the body, so as to render it difficult to form a conclusion on death from apoplexy or asphyxia (Gerichtliche Leichen-Öffnungen, i. 89).

The special researches on drowning made by Casper and Kanzler show that putrefaction of the bodies of the drowned generally commences at the upper part and extends downwards. Thus, after a few days, while the lower part of the body may be in a tolerably fresh condition, the face, head, neck, and upper part of the chest may present a reddish colour passing into patches of a bluish green, first seen on the temples, ears, and nape of the neck, thence spreading to the face, and afterwards to the throat and chest. These changes may be observed in summer when a body has remained in water from eight to twelve days, and in
winter at a still later period. The head of a drowned person is sometimes much discoloured from putrefaction, when the rest of the body may preserve its ordinary condition. Casper considers that this inverted order of the putrefactive process may be taken as a strong indication of death from drowning. (Ger. Leich.-Oeff. ii. 103); but while it may be admitted that attention should be given to this circumstance, it yet remains to be proved whether a dead body thrown into water (when death has taken place from asphyxia by suffocation or strangulation) would not undergo decomposition in a precisely similar manner. It is worthy of remark that the uterus resists decomposition more than other internal organs. In a case in which the body of a female, who had been missing nine months, was found and examined, although all other parts were completely decomposed, the uterus was of a reddish colour; firm in structure, and its parts recognisable, so that Casper, who examined the case, was able to affirm that the female was not pregnant at the time of her death (Ger. Leich.-Oeff. i. 93).

Abrasions.—There is another external appearance which is sometimes met with in the drowned: the fingers or surface of the body may occasionally present abrasions; and gravel, sand, or other substances, may be found locked within the hands or nails of drowned subjects; for in the act of drowning, as common experience testifies, an individual will grasp at any object within his reach, and in his efforts to extricate himself he may exorci\--or wound his fingers. There are, however, many cases of drowning, in which this appearance is absent. There may be no substance for the drowning person to grasp;—this will depend in great degree upon the fact of the water being deep or shallow, of its being confined within a narrow channel or not, and many other contingencies. In all cases, when the individual is senseless before he falls into the water, or when his death is occasioned by syncope from sudden terror, he will, of course, be incapable of making those exertions which are necessary to the production of this appearance, and it is probable that this frequently occurs among females who are accidentally drowned. When the body has remained several days in water, the skin of the palms of the hands and soles of the feet is found thickened, white, and sodden, as a result of imbition.

2. Internal Appearances.—On examining the body internally, we may expect to find, in a recently drowned subject, that the viscera of the thorax will present the appearances usually indicative of asphyxia.

The Blood.—The venous system is generally gorged with dark-coloured blood. If death has not taken place from asphyxia, or if the subject has remained a long time in water before an inspection is made, the viscera of the thorax will not present the characters about to be described. Some physio-
logists have asserted that the blood remains fluid in the bodies of the drowned. Orfila observes, that, with one exception, he has not met with blood in a coagulated state, in the examination of a drowned person. Much more importance has been attached to this appearance than it really merits. Some observers have found the blood coagulated in the drowned; and I have repeatedly seen coagula, like those usually met with after death, in the bodies of animals which were drowned for the sake of experiment. If the blood be generally found liquid, this may be due to the imbibition of water, or to putrefactive changes. The state of the blood in the drowned, formed a subject of inquiry in the case of Reg. v. Barker and others (York Winter Ass. 1846). From the remarks above made, it will be perceived that it may be found either coagulated or uncoagulated in those who go into the water living, and die by drowning.

The Lungs.—The state of the lungs is of considerable importance: they are more frequently found distended than collapsed. According to Dr. Riedell, they are very flabby and greatly increased in weight. The accurate observations of Casper and Kanzler show that the lungs of the drowned are, as a general rule, greatly increased in volume: they appear as if they were inflated, and completely fill the cavity of the chest. This increase of volume does not depend entirely on that congestion or fulness of blood which is a result of asphyxia in drowning; for Casper states he has met with this augmentation of volume in those cases where death has taken place suddenly in the water from apoplexy or other causes than asphyxia (Ger. Leich.-Oeff, ii. 112).

The Heart.—The state of the heart in the drowned has given rise to some discussion. In asphyxia, the right cavities are, I believe, generally found to contain blood; while the left cavities are empty, or contain much less than the right. Out of fifty-three inspections made by Dr. Ogston, the right cavities were found empty only in two cases, and the left cavities empty in fourteen (Med. Gaz. Vol. xl.viii. p. 291). In a case of drowning, which was examined by Mr. Bishop (post 739), it will be perceived that the right side of the heart contained scarcely any blood; and another case has been communicated to me (Dec. 1837), in which the only medical difficulty regarding death by drowning, presented itself in an emptiness or nondistension of the right cavities of this organ. The facts and observations accumulated by my friend, Dr. Norman Chevers, of the Calcutta Medical Board, show that a full condition of the heart, although a common, is not an invariable, concomitant of asphyxia, from drowning or from any other cause (Medical Jurisprudence for India, 1856, p. 441). It has been elsewhere remarked, that the action of the heart continues after the stoppage of respiration, and that the period at which this organ ceases to
contract is variable. Hence, in some cases, there may be sufficient power in the right cavities to contract upon their contents, and to expel, more or less completely, the last traces of blood received by them from the body. Emptiness of the right cavities of the heart must not, therefore, be regarded as inconsistent with death from drowning (See cases pp. 743, 752, post); at the same time, it cannot be taken as a proof that the person has died from asphyxia. As in death from strychnia, prussic acid, and other causes, the condition of the right cavities of the heart as to fullness or emptiness, is more closely connected with the mode of dying, than with the actual cause of death.

The Brain.—A greater or less fullness of the vessels of the brain is described as one of the appearances met with in a drowned subject; but this, when it exists, is probably a consequence of a congested state of the lungs. Some remarks have been already made on this subject, and from these it is evident, that the state of the cerebral vessels can afford no presumption that death has taken place by drowning. In regard to the cases which I have had an opportunity of examining, the quantity of blood contained within the cerebral vessels has rarely been so great as to call for particular notice.

The Stomach.—In examining the viscera of the abdomen, it will commonly be found that the stomach contains a certain quantity of water, which appears to enter into this organ by deglutition. This may be salt or fresh according to the medium in which the drowning has taken place. The quantity is subject to great variation; sometimes it is large, at other times small; and in some instances, no water whatever is to be met with. The absence of water may probably indicate a very rapid death, as there could have been no power to swallow. Orfila has remarked, that the mucous membrane of the stomach and bowels is occasionally much discoloured in drowned subjects. He observed, also, that when drowning took place while the process of digestion was going on, the mucous membrane of the stomach often had a pinkish red or violet tint. When the drowned subject had remained a long time in water, this membrane was observed to acquire a very deep violet or brown colour. A knowledge of this fact will be of importance in those cases in which the subject removed from water is suspected to have been poisoned previously to submersion. Among the other internal appearances met with in the body of a recently drowned person, which require to be mentioned, is the presence of a mucous froth, sometimes of a sanguineous hue, covering the lining membrane of the trachea, which may be itself slightly reddened. Water is, also, occasionally found in the ramifications of the air-tubes, but in very variable quantity. If the body has remained a long time in water, or if, after removal, it has been exposed to the air several days previously to an inspection being made, there is
commonly no appearance of mucous froth in the trachea or its ramifications. It has been said that the diaphragm is generally much raised towards the chest, but this depends on putrefaction, and the increase in the size of the abdomen by the formation of gas in the intestines. The urinary bladder in some cases contains urine; in others it is perfectly empty. Casper found it empty in one-half of all the cases which he examined. It is obvious that the state in which the bladder is found must depend on its condition at the time at which the drowning occurred. (See, in reference to the appearances in the drowned, a paper by Dr. Ogston, Med. Gaz. Vol. xlvii. pp. 763, 854, et seq.; also another by Dr. Riedell, Med. Gaz. xlvi. p. 478; and Casper, Ger. Leich.-Oeff. i. 87, ii. 105.)

Cases.—Mr. Bishop communicated to me the result of an inspection made by Dr. Bull, of Hereford, and himself, in the case of a female whose body had been in the water about an hour and a half. The inspection was made twenty-four hours after death. The contracted state of the skin (cutis anserina) was well marked. The vessels of the membranes of the brain were somewhat congested, the principal seat of engorgement being at the base. The tongue was neither swollen nor indented, but pallid. Mucous froth in considerable quantity was found in the wind-pipe;—the vesicles were exceedingly minute in the upper part, but at the lower portion of the tube they were as large as a mustard seed. A small quantity of clear fluid flowed through the bronchial tubes when the lungs were raised. The lungs were not collapsed; they crepitated on pressure, and were rather bloodless anteriorly; posteriorly they were somewhat gorged with blood, apparently from gravitation. The stomach had about a pint of fluid in it, which seemed to be water mixed with some undigested meat. The lining membrane was slightly pink in colour. The right side of the heart was very flabby, and contained scarcely any blood. The blood throughout the body was quite fluid. The appearances of asphyxia were not so well marked in the lungs and heart of this subject as they usually are; nevertheless, the state of the trachea, bronchial tubes, and stomach, was quite characteristic of death from drowning. As a contrast to this, and as showing the variable nature of the appearances met with in the drowned, the following case, reported by Professor Dunglison, may be quoted.

A woman, in full health, was observed to be intoxicated on the banks of the Schuylkill, U. S., about one hour before her body was discovered in very shallow water. She could not, therefore, have remained long under water. The body was examined by Dr. Farquharson, one of the resident physicians, about sixteen hours after death. The face was swollen, and of a mottled purple colour. The arms and thighs presented patches of discoloration, and a small quantity of whitish froth.
issued from the mouth, the amount of which was not increased by pressure upon the chest, although a small quantity of watery fluid escaped when the body was turned over. On opening the chest, numerous old pleuritic adhesions were found, on the removal of which, and by the consequent compression of the lungs, a discharge of watery froth took place from the mouth. All the parts of the pulmonary tissue were gorged with blood, and were much heavier and of a darker red colour than in the normal state. The posterior portions of both lungs were more engorged underneath, or from position. The trachea and bronchial tubes contained the same kind of watery froth or frothy mucus, as that which had issued from the mouth. The liver was large, engorged, and of a bright red colour. The right cavities of the heart and the coronary veins were filled with dark fluid blood. The left cavities were empty. Such, observes the Professor, are the main phenomena occasioned by the mode of death— asphyxia from drowning. (Phil. Med. Examinor, March, 1845, 169.)

Mr. Semple, of Islington, reported in the Lancet (May 29, 1841), two cases of drowning, in each of which he had made a careful inspection of the body. The subjects were both adult females. In one, the cerebral vessels were nearly empty,—the lungs rather voluminous: the bronchial tubes containing a small quantity of frothy mucus,—and the right side of the heart contained a quarter of a pound of fluid blood. There were slight marks of inflammatory redness about the mucous membrane of the stomach and intestines,—accounted for in the stomach by digestion going on at the time of death. The organ contained about a quart of fluid matter, consisting of food mixed with water, probably swallowed in the act of drowning; there were no traces of poison in the stomach or marks of violence on the body. In the other case, the eyes were half open, hands not clenched, fingers straight:—cerebral vessels very much congested. The lungs were distended; trachea empty; bronchial tubes in their smaller ramifications filled with a soapy (?) tenacious mucus. The right side of the heart and larger veins were distended with fluid blood. The oesophagus contained a clear watery fluid, and in the stomach, there were three ounces of a clear fluid destitute of smell and colour, with the exception of a green tint from a minute quantity of vegetable matter, resembling the conserve of ponds. Liver much congested: This woman was found drowned in a shallow pond. Both subjects were examined recently after death.

_Was death caused by drowning?—_ It is obvious that for a correct solution of this question, we shall have to consider the appearances met with in the bodies of the drowned, and to determine how far they are characteristic of this form of death. Among the external signs of drowning, when the body is seen soon after
WAS DEATH CAUSED BY DROWNING?

741

dehth, are paleness of the surface, a contracted state of the skin (cutis anserina) and the presence of a mucous froth about the nostrils and lips. The absence of these appearances, however, would not prove that the individual had not been drowned; for if the body has remained some time in water, or if it has been long exposed to air before it is seen by a medical practitioner, the skin may have undergone various changes in its condition and colour, and mucous froth may no longer be found adhering to the nostrils and lips.

State of the skin.—The goose-skin or cutis anserina is frequently observed in the drowned, and according to Casper it is a common accompaniment of death by drowning. Like the other appearances it is not always met with, and a question has arisen whether when it exists, it can be regarded as an unequivocal sign of death from drowning, or rather of a person having gone into the water living. Wagner believed that it might occur in a dead body submerged while still warm; but in Casper's opinion, the most important fallacy to which this appearance is liable, is the fact that many persons have naturally a hard rough or horny skin, which might be mistaken for the goose-skin, resulting from contact with cold water. (Ger. Leich.-Oeffn. i. 89.)

Substances grasped in the hand.—In speaking of the external appearances of the body, it was stated that foreign substances are sometimes found locked within the hands, or lodged under the nails of drowned subjects. This fact may occasionally afford strong circumstantial evidence of the manner in which the individual has died. If materials be grasped within the hands of the deceased which have evidently been torn from the banks of a canal or river, or from the bottom of the water in which the body is found, we have strong presumptive evidence that the individual died within the water. For although it is possible to imagine that the deceased may have struggled on the bank and have been killed prior to submersion, yet in the value attached to this sign we are presuming that there are no marks of violence on the person, nor any other appearances about the body sufficiently striking to lead the examiner to suspect that death has taken place in any other way than by drowning. If the substance locked within the fingers or finger-nails, be sand of the same character as that existing at the bottom of the river or pond, it is difficult to conceive any stronger evidence to establish the fact of death having taken place subsequently to submersion. The abrasion of the fingers is a circumstance of minor importance,—no value could be attached to this state of the fingers as an indication of the individual having perished by drowning, unless it were in conjunction with the appearances above described. A witness would be constrained to admit, in many cases, that the extremities of the fingers might become abraded
or excoriated after death, or even before submersion, while in no case could he be called upon to make, in regard to substances found grasped within the hands, an admission which would invalidate the evidence deducible from this condition. This must be regarded as satisfactory evidence of the individual having been alive after his body was in the water. It is well known that when two or three persons are drowned by the same accident, they are not unfrequently found clasped within each other’s arms,—a fact which at once proves that they must have been living when submerged. So if a dead body be discovered still holding to a rope, cable, or oar, no further evidence is required to show that the deceased must have died by drowning. The signs upon which medical jurisists chiefly rely as proofs of death from drowning, are,—1. water in the stomach; and 2. water with a mucous froth in the trachea and lungs.

Water in the stomach. — It has been remarked, that water commonly passes into the stomach of a living animal while drowning, and this most probably takes place by the act of deglutition. It has been observed, that when an animal is stunned prior to submersion, water does not pass into the oesophagus, and when syncope occurs none will be found. As a proof that its entrance into that organ depends on deglutition, it may be stated that the quantity contained within the stomach is greater when the animal is allowed to come frequently to the surface and respire, than when it is maintained altogether below the surface. The power of swallowing is immediately suspended on the occurrence of asphyxia, and in this way we may perhaps satisfactorily account for the difference observed in the two cases. The water thus found is in variable quantity; and there are some cases of drowning in which water is not discovered in the stomach. It was found by Dr. Ogston of Dundee, in five cases out of seven. (Ed. Med. and Sur. Jour. Jan. 1837.) In dissecting cats, which had been drowned, I have repeatedly remarked the absence of water from the stomach; in these instances, the animals have been invariably kept under water from the first moment of their submersion, and thus in a condition but little favourable to the exercise of deglutition. Water does not readily penetrate into the stomach of a body which has been thrown in after death; the sides of the oesophagus applying themselves too closely to each other, to allow of the passage of the fluid. If putrefaction has advanced to any extent it is possible that some water may enter; but the practitioner will easily judge from the general state of the body how far this process may have been concerned in the admission of fluid into the stomach and alimentary canal. Orfila has suggested that water may be found in the stomach of a subject apparently drowned, in consequence of this liquid having been drunk by the individual, or artificially injected by another into the stomach after death. It is difficult to conceive
under what circumstances such an objection could be made, or what purpose it would answer. In relying upon the presence of water in the stomach it must not be forgotten that the deceased may have drunk water before his body was submerged. The body of a child aged two years was taken out of a piece of water and inspected. The usual appearances of drowning, with one exception, were absent. There was no congestion in the brain or lungs, there was emptiness of the cavities of the heart, no water in the air-passages, and thus a want of evidence of death from apoplexy or suffocation. The blood was of a clear red colour, and very fluid: the stomach was almost filled with water, in which a portion of the food floated. No cause of violent death was apparent on inspection. The presence of water in the stomach was explained by the fact that the child had been playing with its nurse on the banks of the stream. It complained of intense thirst, and the nurse gave it a copious draught of water. Almost immediately after this, the nurse having walked away, the child must have fallen from the bank into the water (Casper, Ger. Leich.-Oeffn. i. 91). The discovery of water in the stomach, except under circumstances to be presently mentioned, is not, therefore, a necessary proof that it has been swallowed during the act of drowning (see case, post, page 755).

It is of course presumed that the liquid contained within this organ is of the same nature as that in which the body is immersed; for it is possible that fresh water may be found in the stomach of a person drowned in salt water, and in such a case it would be obviously improper for a medical witness to affirm, from the mere existence of water in this organ, that the individual had died within the medium in which his body was discovered. If the water contain mud, straw, duckweed, moss, or any substances existing in the pond or river, where the drowning occurred, this is a proof, when the inspection is recent, of its having been swallowed by a living person. In the well-known case of Mary Ashford (Rex v. Thornton, Warwick Summer Ass. 1817), some duckweed with about half a pint of water was found in the stomach of the deceased. The body was discovered in a pond in which duckweed was growing. This fact, notwithstanding the presence of other marks of violence, proved that the deceased must have been living when immersed. The following case occurred at Maidstone, in July 1843. The body of a young woman was found in the Medway under circumstances that led to a strong suspicion of murder. The medical witness deposed that there were no marks of external violence, nor any sign of the deceased having struggled with the supposed murderers. There was some long grass at the back of the mouth, and in the throat. The grass was not the same as that growing on the banks of the river, but such as grew at the bottom, and which
the deceased had probably swallowed after having gone living into the water. On this evidence the accused was discharged. In another case investigated by Mr. Image (Reg v. Curn. Bury St. Edmunds Lent Assizes, 1851), the body of deceased was found with her head among water weeds, some of which were discovered in her throat, and the finger-nails were filled with sand and mud, as if clutched convulsively. These facts aided in proving that deceased had died by drowning. The absence of water from the stomach cannot, however, lead to the inference that the person has not died by drowning, because in some instances it is not swallowed, and in others it may drain away and be lost after death.

Mucous froth in the trachea and lungs. — The interior of the trachea in a drowned subject is frequently covered by a mucous froth, and this is stated in some instances to have been so abundant as to have filled the air-tubes and their ramifications. It is sometimes disposed in a layer of minute vesicles tinged with blood. The origin of this appearance has been variously accounted for; but it is probable that it is produced by the simple agitation or admixture of the air respired during the act of drowning with the mucous secretion of the air-passages, which perhaps under these circumstances is more copiously poured out. This mucous froth is not always met with in drowned subjects: 1. It has not been found in the bodies of those who have sunk at once below the surface. 2. The appearance may not be seen when the body has remained for a long period in the water after death, since by the free passage of this fluid into and out of the air-passages, the mucous froth, although formed in the first instance, will disappear. 3. If, after removal from the water, the subject be exposed to the air for several days before it is examined, it is rare that this appearance is seen. 4. The mucous froth may have been formed in the wind-pipe, but it may have entirely disappeared, owing to the incautious manner in which the body has been handled on its removal from the water. Thus, if the subject be removed from water with the head depending, any fluid which may be contained within the lungs will escape; and in passing through the air-passages this fluid will effectually obliterate the frothy appearance. A similar appearance has been found in the bodies of those who have been hanged, or who have died from apoplexy. The introduction of any liquid into the wind-pipe during deglutition, may produce it. A case of poisoning by laudanum is reported, in which water containing sulphuric ether was forced down the throat of a person after the power of swallowing had ceased. On dissection a quantity of reddish froth was found filling up part of the trachea. Dr. Riedell looks upon the presence of this froth in the air-tubes as a constant sign of death by submersion, when the body is recently inspected (Med. Gaz. xlvi. p. 478). In some cases the con-
tents of the stomach are found in the wind-pipe and lungs. This occurs when the person has been drowned with a full stomach. Vomiting takes place, and the vomited matters are drawn into the lungs by the attempt to breathe.

**Water in the lungs.**—Many contradictory statements have appeared relative to the presence of water in the lungs of the drowned. It is an appearance only occasionally met with: for the glottis does not in every case of drowning become so effectually closed by spasm, as to prevent the introduction of a small portion of liquid into the air-passage. In certain cases no water is found in these passages after death, and when present, the quantity depends on many contingencies. It is commonly small, often about an ounce, but it is subject to variation, and is probably affected by the number of forced attempts at respiration made by the drowning animal. In experiments on animals, I have not remarked any difference in the quantity whether the animal was allowed to rise to the surface and respire, or whether it was maintained altogether below. There is but little doubt that the quantity may become increased after death, because it is now well known that water will penetrate into the lungs, before the access of putrefaction, when a body has been thrown in dead. It is important for a medical jurist to bear this in mind, as it may influence materially the opinion which he may be disposed to form on the discovery of water in the lungs of an apparently drowned subject. Water may therefore be present in the lungs, and yet it will afford no evidence of drowning. When the water in the lungs is mixed with weeds or mud, and water presenting the same admixture is found in the throat and stomach, this is strong evidence that the body has been plunged into the medium when the power of breathing and swallowing still existed, and hence that the deceased has been drowned. An attention to the condition of the stomach and lungs together, will therefore be of importance in cases of alleged child-murder by drowning, since it may aid in proving or disproving the charge. In a case tried at the Central Criminal Court, April 1851, in which I was consulted by Mr. Tyte, of Harrow, some greenish-coloured mud was found in the throat, lungs, and stomach of an infant whose body had been removed from a pond. The prisoner was acquitted, because it was suggested that she might have thrown the body of her child into the water, when she believed it to be dead, and one or two gasps might have accounted for the appearances presented by the stomach and lungs.

Dr. Norman Chevers, of Calcutta, was required to examine the body of a child found in a tank at a distance from the house of the parents. The internal appearances showed that the child had died by drowning. The air-passage contained green vegetable matter, and the right air-tube was almost completely filled with so large a portion of an aquatic weed doubled to
gether, that it appeared astonishing how such a body could have passed into the wind-pipe. It was proved that no weed of this kind grew in the tank where the body was found. Further inquiry led to the discovery, that the body of the boy had been found by a woman in a tank near his home, in which the weed found in the air-passages grew abundantly. This female conveyed the corpse to the more distant tank which belonged to a person against whom she bore a grudge! (Medical Jurisprudence for India, 1856, p. 441.)

It has been suggested that water may be injected into the lungs after death, in which case an incorrect opinion might be formed from its presence, if the body were discovered on the bank of a river or canal. This, however, is an obstacle but little likely to interfere with any medical investigation. On the other hand, the absence of water from the lungs of a body found apparently drowned, must not be considered to indicate that death was not a consequence of drowning; for if the body of a drowned person be allowed after removal to remain with the head depending, the water originally contained within the air-passages will drain out; or if it be long exposed before undergoing an examination, the probability is that none will be discovered in these organs, since in the progress of time, it may disappear by imbibition and evaporation.

Want of evidence on inspection. — It may be fairly considered that after the lapse of five or six weeks, especially if the body have been removed from the water for the greater part of that period, none of the usual appearances of drowning will be met with: in the present day, no practitioner would think of seeking for evidence under such circumstances. The medical opinions expressed by the witnesses for the prosecution at the trial of Spencer Cowper, for the murder of Sarah Stout (Hertford Assizes, 1699), are therefore worthy of remark, if only as affording an example of what is to be avoided on these occasions.

The body of the deceased was found floating in a stream probably not more than thirteen hours after she was missed. It was buried, and six weeks afterwards was exhumed and examined. No water was found in the stomach or lungs, which were not putrefied. Six medical men deposed, that when a person was drowned, water was invariably taken into the stomach and lungs; and as none was found in this instance, they were of opinion that deceased came to her death by some other means; — in other words, that, as alleged in the indictment, she had been murdered by the prisoner, and her dead body afterwards thrown into the water! The prisoner asked one of these witnesses, whether, after six weeks' time, water would remain in the body? The reply was that there should be some, because "it can't come out after the body is dead, but by putrefaction; and there was no putrefaction." The witness does not appear to have had the least suspicion that
THE CASE OF KIRWAN.

the deceased might have died without swallowing any water, or
that the quantity swallowed might have been small, and entirely
lost in six weeks by transudation through the soft coats of the
stomach. The prisoner was acquitted.

A case presenting some remarkable features in reference to
death by drowning, was the subject of a trial at the Commission
Court, Dublin, in December 1852 (The Queen against Kirwan.
Report by J. S. Armstrong, Dublin, 1853). The prisoner was
charged with the murder of his wife. He was an artist, and
had gone with his wife, on the 6th September, 1852, for a day's
excursion, to a small island not far distant from Howth harbour.
When the men who took them over in the morning returned to
fetch them about eight o'clock in the evening, the prisoner only
was seen on the shore; and on being asked where his wife was,
said that he had not seen her for more than two hours, and that
she had gone to bathe. After searching for some time, the body
of deceased was found about ten o'clock, lying on her back, on a
small rock just out of the water, between high and low water
mark, the tide having fallen. Her bathing suit was on her about
her waist, and a sheet was beside her and partly under her: she
had on bathing boots. Her clothes were ten or fifteen yards
from where her body was found, on a rock about six feet above
the water's edge. It was a spot where ladies were in the habit
of bathing. It was stated by several witnesses, that about seven
o'clock on the evening on which the body was found, cries or
screams, as of a person in distress, were heard to proceed from
the direction of the island, and apparently from this spot. The
body was superficially examined the next day by a medical gen-
tleman, and he found abrasions of the skin around the eyes, and
a scratch on the right temple. The face was rather pale. Froth
issued from the mouth, but there was no appearance of blood
mixed with it. There was a stain of blood on the cap, about the
size of a five-shilling piece, which appeared to have come from
one of the ears. He saw no wound or other marks of violence
about the body,—nothing to show that the deceased had not died
by drowning. On the 6th of October, thirty-one days after
death, and twenty-six after interment, the body was re-examined
and for the first time carefully inspected by Dr. Hatchell. It had
been lying nearly a month in a wet grave, and was to a certain
extent “inacerated.” The water had had the effect of hastening
the decomposition of the surface of the body. There was no
mark of violence on the scalp: there were abrasions, or marks
of scratches, on the prominent part of the right cheek under the
right eye. The eyes were protruded from decomposition. There
were no injuries outside, inside, or behind the ear: the upper
lip was swollen, and the tongue protruded between the teeth:
the tongue was marked by the teeth both above and below.
There was a sort of scabby matter about the mouth, such as
usually presents itself in bodies which are in an advanced state of decomposition. The brain was of a light pinkish colour, and fluid from decomposition. There was no fracture of the skull, and nothing remarkable in the air-passage. There was a superficial cut or scratch under the nipple of the right breast. There was an appearance of congestion about the organs of generation. The lungs were congested at the back and lower part, arising from engorgement of blood. The internal organs were not decomposed. The heart was healthy; its cavities, as well as the large vessels leading to it, were empty. The stomach was found empty and contracted. The generative organs were carefully examined, but there was no wound in or about these parts.

The cause of death, in the opinion of this witness, was asphyxia, or a sudden stoppage of respiration. Owing to the congested state of the vagina and the engorgement of the lungs, he thought that the simple stoppage of respiration must have been combined with pressure of some kind, or constriction. Simple drowning (i.e., drowning alone) would not produce the appearances. The engorgement was greater than he had ever seen in cases of drowning, and he did not think it compatible with drowning alone; but he at the same time admitted that the engorgement was subject to great variation, and might be great if a drowning person struggled to save himself:—"The appearance presented by the lungs must have been caused by struggling. I (continued the witness) think it very likely that the appearance of the vagina would have been occasioned by struggling in the water for life." The witness was not prepared to say whether death was or was not caused by a sudden fit on the deceased entering the cold water. The prisoner was found guilty, but capital punishment was subsequently commuted for transportation.

The moral circumstances of the case were, as I am informed, strongly adverse to the prisoner. He was of bad moral character, and the account which he gave of the disappearance of his wife was not satisfactory. It was said that the circumstances under which the body was found were such, that its position on the rock could not have resulted from any accident. These points of circumstantial evidence, however, rested on the statements of witnesses who differed from each other. Owing to the body not having undergone a proper inspection until a month after death, the case presented considerable difficulties respecting the cause of death. One view was that the deceased was smothered; another that she was strangled, and the body placed after death in the position in which it was found; and a third that she was accidentally drowned. Viewed apart from the moral circumstances, the inspection of the body threw no light on the cause of death.

The dead body of a person may be found in water under circumstances which may lead to a strong but erroneous suspicion of homicidal interference. The following case occurred in May
1854:—A gentleman, aged 30, who had retired to his dressing-room in apparently good health, was for some time missing, and on breaking open the door his body was found lying in a sponging-bath which he was in the habit of using. He was quite dead, but there was still some warmth about the body. He was lying on his face in the bath, with his nose and mouth below the level of the water. Some time before he was thus discovered, a fall had been heard in his room; but no particular notice was taken of it. The body was inspected twenty-four hours afterwards. Externally there was a recent wound of the skin of the right arm above the wrist,—this had apparently been caused by pieces of a wash-hand basin which had been broken. There was strong and well-marked congestion of the brain and membranes. The heart was slightly enlarged, and the walls of the left ventricle thickened. In the right ventricle only a small clot of blood was found: with this exception the cavities were perfectly empty. There was some cartilaginous deposit in the aortic valves. The right lung was healthy, and presented no congestion; the left was wasted but slightly congested. An inquest was held, when the medical and other evidence tended to show that, although the body was found with the face under water, the deceased had not died from drowning, but that he had been seized by a fit, probably epileptic,—that he had fallen into the sponging-bath, breaking the wash-hand basin in the fall, and thus producing the recent wound of the right arm. It turned out that he had previously had two epileptic fits. Mr. Keseveen relates a singular case in which a man, who was just about to jump into the water to rescue a boy who had fallen in by accident, was suddenly seized with paralysis and died in three hours. On examination there was effusion of blood on the brain, and this accounted for the apoplectic seizure (Med. Gaz. Vol. xliv. p. 295).

CHAPTER LVII

SPECIFIC GRAVITY OF THE HUMAN BODY LIVING AND DEAD—

Specific gravity of the human body. — At the trial of Spencer Cowper (ante, p. 746) for the murder of Sarah Stout, the buoyancy
of the human body, living and dead, formed an important part of the inquiry. The body of the deceased was found floating at about five or six inches below the surface of water in a pool which was only five feet in depth. From this circumstance it was assumed that deceased could not have gone living into the water, because, as it was alleged, and attempted to be proved by scientific as well as nautical testimony for the prosecution, the body of every living person who died in water sank, while a dead body thrown into water floated! A sailor was called to support this strange piece of nautical philosophy; and although his statements were contradictory, he swore that in all the battles and shipwrecks, in which he had been engaged, he had uniformly observed that those who were drowned, sank; while those whose bodies were thrown in dead floated! Hence he contended, it was necessary to attach weights to the bodies of those who died at sea. “Why,” said this witness, “should Government be at that vast charge to allow threescore or fourscore weight of iron to sink every man, but only that their swimming about should not be a discouragement to others?” (Smith: Anal. of Med. Ev. 278.) The medical witnesses for the prosecution contended themselves with stating that the bodies of persons who were drowned, sank, without taking into consideration that there were circumstances here which might have accounted for the floating, and have entirely set aside the hypothesis of death before immersion. This female was drowned in her clothes; there were some stakes near the body, which might have aided in supporting it; and the presence of air or gases in the intestines, or in the clothes, would have sufficed to explain a simple fact, by which the Court and scientific witnesses appear to have been completely bewildered. Other sailors were called for the defence, who depose, that after battles and shipwrecks, they had always observed the bodies of the dead to sink, and that weights were attached to bodies buried at sea, not for the purpose of sinking them, but of preventing them floating afterwards by putrefaction. Although it is not likely that the life of any one will ever again be endangered by a question of this kind, it is proper to state a few facts connected with the specific gravity of the human body.

The specific gravity of the human body, in the living healthy state, is made up of the combined specific gravities of its different parts:—so that, as in all heterogeneous solids, it is a very complex quantity. The only part of the body which is lighter than water, is fat. The specific gravity of this is 0·92, and it is calculated that the proportion of fat in an adult forms five per cent. of the weight of the body, or one-twentieth part. The specific gravity of muscle is 1·083, of brain 1·04; and of bone—the heaviest part of the body—2·01. The lightness of the fatty portions is more than counterbalanced by the weight of the skeleton (about ten
and a half pounds in the male, and nine pounds in the female), so that the naked human body, placed on water has a tendency to sink. This tendency diminishes just in proportion to the quantity of the body immersed:—because all those parts which are out of water, not being supported by water, become so much additional absolute weight to the portion immersed. Hence the frequent cause of death by drowning. An inexperienced person exhausts himself by exertion, raises his arms continually out of the water, and as often sinks owing to their weight having just so much effect on his body as if a leaden weight had been suddenly applied to his feet to sink him. When the whole of the living body is immersed, the specific gravity, owing to the expansion of the chest, differs so little from that of water, that very slight exertion will suffice to keep an individual on the surface. From what has been observed relative to the component parts of the body, there are two circumstances which must cause its specific gravity to vary. If the quantity of fat be abundant, it will be diminished; and such an individual will float more readily than another in an opposite condition. On the other hand, the abundance of bone will render a person heavier than his bulk of water; and his body will sink more rapidly than that of another. Now these two modifying cases of buoyancy are liable to constant variation; hence the different accounts given by experimentalists relative to the specific gravity of the human body. The bodies of females are, ceteris paribus, of less specific gravity than those of males: the skeleton is smaller, and there is a greater abundance of fat, hence they more readily float. Very young children float with the greatest ease; the quantity of fat is usually in large proportion and the bones are light,—the earthy matter being not yet fully deposited. Thus in infanticide by drowning, the body of the child rises very speedily to the surface,—if, indeed, it does not remain altogether upon it.

There are some other points to be considered in relation to the buoyancy of the living human body. 1. Respiration.—It is the fact of the lungs being filled with air that gives the general lightness to it. If these organs were emptied, and the chest contracted, then the specific gravity would be considerably increased: hence it follows, that, ceteris paribus, an individual with a large and capacious chest floats more readily than one whose chest is small and contracted. Hence, also, in a living person, the body has a tendency to rise out of water during inspiration, and to sink during expiration:—the quantity of water displaced under these two opposite conditions of the respiratory organs being very different. The entrance into water with the chest nearly emptied as the result of a loud scream or shriek is very unfavourable to the buoyancy of the body.

2. The fact of clothes being on the person will make a differ-
ence; either, from their nature, serving to buoy up the body, or to sink it more deeply. Females are sometimes saved from drowning by reason of their clothes floating and presenting a large surface: and it is partly owing to this circumstance that the bodies of drowned females often remain floating on the water immediately after death. This happened in the case of Sarah Stout (ante, p. 750). In a case of suicide at Plymouth (January 1849), it was proved at the inquest that the body of the deceased floated on the sea-water for half an hour after the act of drowning. It was probably buoyed up by the clothes. But it is to be observed that the specific gravity of sea-water is 1.026. This differs but little from the specific gravity of the muscles and soft organs: hence the human body floats much more readily in sea than in fresh water, and indeed, except for the weight of the skeleton, it would have but a very slight tendency to sink in the sea. I have found by experiment that every structure of the human body excepting bone floats in the water of the Dead Sea, which is remarkable for its great specific gravity (1.117). I am indebted to Mr. W. J. Cooper, coroner for Portsmouth, for the account of a case, in which a drunken man, aged 40, who had gone to bathe in the sea, was accidentally drowned. The body did not sink. It was observed to be floating with the face downwards, and the mouth below the level of the water: when turned over, froth issued from the mouth: the man appeared to be alive, but not sensible. An attempt was made to resuscitate him by the aid of the warm bath and other means: this failed, probably owing to the deceased having first undergone the popular mode of treatment, namely:—being turned on his back to let out the water, and then carried from the beach with his head downwards and back upwards! The appearances met with in the body were somewhat peculiar. The lungs were fully inflated, but there was no bloody mucus or water. In the wind-pipe and left bronchial tube, portions of the contents of the stomach were found (pieces of cabbage, &c.); the heart was perfectly empty (see ante, pp. 738 and 743); the stomach contained a quantity of food half digested, but no water. The medical witness attributed death to apoplexy, followed by an attack of vomiting during which a portion of the food had been drawn into the wind-pipe by an effort to breathe. The floating was probably owing to the average specific gravity of the man's body not being greater than that of sea-water. The bodies of females have been often found floating on the surface of ponds or rivers, within a few hours of the period at which death by drowning must have occurred. Mr. Procter, of York, informs me, that a woman who was seen on the banks of a river at half-past eleven in the evening, was found drowned at eight o'clock the following morning. The body was floating on the water with the face downwards. In December 1853, another case occurred, within
my knowledge. A factory girl fell into a river while walking along the bank in the evening. The body was found floating on the surface of the water the following morning. In December 1857, an accident occurred at Whitehaven, in which a female was drowned. The body floated immediately after death. The bodies in these cases were clothed, and this may have aided the buoyancy. In the case of Sarah Stout, this simple fact was erroneously taken as an indication of violent death prior to submersion!

It may be laid down as a general rule, that the recently dead body unclothed is, when left to itself, heavier than water, and sinks when immersed. The emptiness of the chest, combined with the fact that the bones and all the soft parts, excepting the fat, are of greater specific gravity than water, offers a sufficient explanation of the sinking. After a variable period, generally not more than a few days, the body will rise again to the surface, and float. The period of its rising will depend—1st, on the specific gravity of the body; 2nd, on the nature of the water, whether salt or fresh; 3d, on the access of heat and air in facilitating putrefaction. If the gases generated find an escape, the body will sink:—more gases may form, and then it will again rise, so that the sinking and rising may become alternate phenomena. A very small quantity of air, derived from putrefaction, will suffice for the floating of a body. Thus, taking the specific gravity of the dead body even at 1.08 or 1.1, it would require but little air to keep it at or near the surface of the water. The bodies of the drowned, when they float from putrefaction, generally rise to the surface about the fourth or fifth day after submersion in shallow water, unless held down by mechanical obstacles. But a dead body may be prevented from sinking at all, partly, as it has been observed, in consequence of the clothes, and partly in consequence of its having been caught and supported by stakes or other obstacles in the water,—or it may be rendered buoyant by the presence of a quantity of air in the intestines or dress.

Surviorship of the drowned. Decomposition in water.—Some medical jurists have proposed the question, whether when several persons fall into water at the same moment, and are drowned, we can determine which among them was drowned first, or which survived the others. M. Derainge attempts to bring forward an answer to this question, from the state of the heart, lungs, and brain; but it is needless to say, that the condition of these organs can furnish no certain evidence. Even if a medical practitioner chose to adopt such hypothetical views, it is certain that they would not be received as evidence by an English Court of Law. When two bodies are found in the same spot in a river, it is allowable to form a limited presumption (from the different
degrees of putrefaction in the two) whether one has been submerged for a longer period than the other.

The body of a drowned person after lying for some time in water undergoes the usual putrefactive changes indicated by discoloration of the skin and muscles, with softening of the animal substance (ante, p. 735); but in some cases, when the circumstances are favourable, a change of a peculiar kind takes place. This consists in the slow conversion of the fatty parts of the body into a species of soap called adipocere. The experiments of Chevreul have proved that this compound is nothing more than an animal soap with a base of ammonia or lime, the former alkali being the result of the decomposition of the nitrogenized principles of the body, while the fat becomes acidified. A medico-legal question has more than once arisen respecting the length of time which a body should remain in water, in order that this adipocerous transformation of the tissues may be observed. Dr. Gibb's, of Bath, found that by macerating muscle in water for about a month, he was able to procure only a small quantity of adipocere. Dr. Harlan, of Philadelphia, observed that the integuments of a cranium were, by maceration, converted into adipocere in about six weeks. In some experiments which I have made on the subject, the conversion of muscle and fat to adipocere was not complete in stagnant water under a period of two months. Thus, then, we may say that a month is about the earliest period at which the change is likely to be observed. The experiments of Orfila and De Vergeje prove, that in bodies interred in the soil, the change is much longer in taking place. The following singular case, which was tried at the Warwick Lent Assizes, in 1805, will show the medico-legal relations of this subject: A gentleman, who was insolvent, left his home on the 3rd November; and on the 12th December following, his body was found floating in the river much decomposed, and the dress rotten. There was no doubt that he had committed suicide. A few days after he was missed, a commission of bankruptcy had been issued against him; and the question was, whether he was or was not living at the time it was issued. If not living, then the commission was void. As nothing positive was known on the subject, the only evidence on the point was derived from an examination of the body. The muscles of the lower part of the abdomen and the glutel were found to have become converted to adipocere; and from this fact, it was inferred to be in the highest degree probable, that his body had been in the water during the whole period of his absence—thirty-nine days; in short, that he had drowned himself on the day he left the house. Several medical witnesses were summoned on both sides. Dr. Gibbes and two others gave a strong opinion, that from the slow formation of adipocere in the drowned, it was reasonable to infer that the body of the deceased had been in the water for the whole period of five weeks and four days. The jury
SUMMARY OF MEDICAL EVIDENCE.

returned a verdict in accordance with this view, namely, that
the deceased was not living at the time the commission was
issued against him. The late Mr. Callaway informed me, that
he was required to give evidence in a similar case in the year
1836.

Summary of medical evidence.—We have now reviewed the whole
of the evidence which the examination of a drowned subject after
death is capable of affording to a medical witness. It will be
seen that the only characteristics met with internally, upon which any
confidence can be placed to indicate that the individual has been
drowned, are the presence of water in the stomach, and the
presence of a mucous froth on the lining membrane of the trachea;
but at the same time, the restrictions to the admission of these
signs as positive evidence of drowning, may be such as to throw
great uncertainty on the correctness of a medico-legal opinion
founded simply on their existence. The practitioner must then
determine, before he decides positively in a question of this nature,
whether there be any appearance about the person which would
lead to the suspicion that death has been caused in another way.
When he has provided himself with this negative evidence, and
he finds that the characters of drowning, already enumerated, are
present, — or, if absent, he can, with any reasonable probability,
account for their absence, he is then justified in giving a decided
opinion on the subject.

A man died suddenly in the Rue St.-Antoine, at Paris, in
February 1830, and the body was soon afterwards brought to the
Morgue. It there underwent a minute examination; but there
was no mark of violence externally, nor was there any morbid
change to account for death internally. In the course of the
dissection, it was found that the larynx, trachea, and air-tubes,
contained a frothy mucus. In the larynx this was white, but it
had a red colour in the air-tubes. M. Devergie, who con-
ducted the inspection, states, that it only differed from the
froth, as it exists in the trachea of the drowned, in the cir-
cumstance of its being in larger vesicles: — but he candidly
owns, that had he not been certain of the contrary, he should
have presumed that he was examining the body of a person
who had died by drowning. Besides this appearance, there was
a large quantity of water in the stomach, amounting to almost
a pint; and the lungs were gorged with blood, as in cases of
asphyxia. Supposing that this body had been thrown into the
river after death, it is clear that most medical men, relying upon
what are usually regarded as well-marked proofs of this kind of
death, would have declared this to have been a case of drowning.
A practitioner could not be censured for forming such an opinion,
since it would be founded upon the best ascertained rules
of past experience; and there are no others by which a medical
jurist can be guided. In the meantime, we learn by the occurrence of such a case, how cautious we ought to be in expressing a positive opinion in a question of this nature, even when medical circumstances exist to support it.

If, however, a case of this kind be of rare occurrence, we will take an instance of an opposite description. An individual may be suffocated, or may die from epilepsy, apoplexy, or from a sudden attack of any fatal disease which may not be indicated by well-marked appearances after death; the body is thrown into or falls into water, and remains there a few days. When taken out, water may be found in the lungs, but there may be none in the stomach; and there may be no mucous froth in the trachea; the lungs may be more or less congested; how is a practitioner to determine whether death has actually taken place within the water or not? In the case of a suffocated body, without traces of external violence, it would be impossible; since we have seen that individuals may die in the water, or at the moment of immersion, and, therefore, under circumstances in which the appearances of drowning would be either obscure or entirely wanting. Dr. Ogston, of Aberdeen, relates a very instructive case of death from epilepsy, under circumstances which might have led to a strong suspicion of violent death, from the position in which a dead body was found. A man was in the act of leaving a privy, when he was seized with an epileptic fit and fell with his face in a piece of dirty water, which did not exceed a foot and a half in breadth, with a depth of from three to four inches. When discovered after death, only his mouth and nostrils and one cheek were found to have been under water. (Med. Gaz. Vol. xlvii. p. 763. See case, ante, p. 749.)

If, in examining a body taken from water, we discovered traces of mortal disease, or marks of external violence sufficient to destroy life, then there is always room for suspicion. Why the body of a person, who has really died from natural causes, should be afterwards thrown into water, it would not be easy to explain: but we can readily appreciate the motive when murderous violence has been used.

In consequence of the uncertainty attendant on the appearances of drowning, barristers have considerable advantage in cross-examining those medical witnesses who appear to support this view. Legal ingenuity is here often carried to the utmost, to show that there is no positive or well-defined sign of drowning: and, therefore, the inference is drawn that the deceased must have died from some other cause. It is undoubtedly true, that there is no constant or certain sign of death from drowning. The general impression among non-medical persons appears to be, that, whether in drowning or suffocation, there ought to be some particular visible change in the body to indicate at once the kind of death; but it need hardly be said that this notion is
founded on very false views; and if the reception of medical evidence on the cause of death be made to depend on the production of some such positive and visible change, then it would be better at once not to place the parties charged with the offence upon their trial, because the crime could never be proved against them. A medical inference of drowning is founded upon a certain series of facts, to each of which individually it might be easy to oppose plausible objections; but, taken together, they often furnish evidence as strong as is commonly required for proof of any other kind of death. A trial took place at the Central Criminal Court, April 1841, in which the witnesses were very severely examined on the appearances caused by drowning. (The Queen v. Longley.) The mother of the deceased child was charged with murder by drowning it. When the body of the child was removed from water, the mouth was closed: the prisoner’s counsel endeavoured to make it appear that it was most usual to find the mouth open in cases of drowning; and then went on to say, “that the only proof of suffocation by drowning which had been adduced by the medical witness was the frothy mucus found in the air-cells; — that it could not have gone through the mouth was quite certain, because the mouth was proved to have been closed. The air might have passed into the air-cells of the child, whilst struggling in its mother’s arms, just as well as whilst struggling in water.” After what has been stated, it is not necessary to point out the fallacy of the assumptions involved in this argument; but it is much to be regretted that medical evidence should be allowed to be presented to a jury in such a perverted form. The wonder is, that even in a case of undoubted criminality (as in that particular instance) a conviction should ever occur. (See also the case of the Queen v. Owen, Thomas, and Ellis, Stafford Lent Assizes, 1840.) In a case in which Mr. Image, of Bury St. Edmunds, gave evidence (Reg. v. Carnt, Suffolk Lent Assizes, 1851,) the medical facts, although furnishing conclusive evidence of drowning when taken together, were individually objected to. The deceased was found dead in a pond. The body was removed after it had been lying about four hours in the water, and was carefully examined by Mr. Image forty-one hours after death. The hair was hanging back, wet, very muddy, with leaves and weed entangled in it; the ears were muddy, the right eye ecchymosed, pupils slightly dilated, lips bluish, and there were bluish patches on the face. Slight scratches were observable on the right side of the face. The skin had a dull leaden hue. The jaws were fixed, teeth tightly clenched, and the tongue not protruding. The nails were filled with sand and mud. There were severe bruises on both arms near the elbow, equal in extent and intensity. The tongue was greatly congested, and covered with froth and mud, which extended backwards to the throat and
nostrils as well as into the larynx and trachea, or windpipe, and the upper divisions of the air-tubes of the lungs. The lungs were engorged and greatly distended: when cut in any part frothy mucus was abundantly poured out, and much fluid escaped on pressure. The heart was healthy; the right and left cavities were filled with black fluid blood. There were no coagula. There were small pieces of green weed in the air-tubes (corresponding to weed in the pond). The vessels of the neck were distended with dark-coloured liquid blood, without any coagulum. The stomach was healthy; it contained partially digested food, with about a pint of liquid mixed with mud and sand. The liver was enormously congested, bleeding profusely at every section. The bladder was quite empty, and contracted to the smallest size. The sinuses of the brain were not much distended, nor was the substance of the organ greatly congested. Mr. Image gave an opinion, which was perfectly justified by the appearances, that the deceased had died by drowning, and that she had probably been held forcibly under water. The accuracy of this opinion was established by the confession of the criminal before execution.

Marks of violence on the drowned.—The chief inquiry with regard to marks of violence on the bodies of the drowned, is, whether they have resulted from accident or design. In forming an opinion, a witness must give due value to the accidents to which a body, floating loosely in water, may be exposed. Ecchymoses of considerable extent are sometimes seen on the drowned, when the bodies have been carried by a current against mechanical obstacles in a river or canal. If the deceased fell from a considerable height into water, his body in falling may have struck against a rock or projection, and have produced a very extensive mark of violence. Dead bodies taken out of wells, often present considerable marks of violence of a vital character, when the deceased persons have fallen in accidentally, or have thrown themselves intentionally. The presence of these marks must not create a hasty suspicion of murder. It is manifestly impossible to lay down any specific rules for forming a decision in cases of this kind, since probably no two instances will be met with which will be perfectly similar. In clearing up these doubtful points, everything must depend on the tact and acumen of the practitioner who is called upon to conduct the investigation. The first point which he has to determine is, whether the injuries on the body were produced before or after death. (See Wounds, ante, page 237.) If after death, then they ought to be obviously of accidental origin. Accidental violence may sometimes be of a very serious nature,—so serious that a practitioner might well doubt whether it did not indicate that the deceased had been violently injured prior to submersion. If a dead body were taken out of water, with one or both extremities dislocated, or the cervical vertebrae fractured,
and a surgeon was asked whether such injuries could be accidental and coincident with, or consequent on drowning, the answer would probably be in the negative; but an instance has occurred in which both arms were accidentally dislocated at the shoulders in the act of drowning. I allude to the case of a man, who, some years since, jumped from the parapet of London Bridge into the Thames. This explicit, it appears, the man had previously performed with impunity, but on this occasion he sank and was drowned. Both his arms were found dislocated, in consequence, it is presumed, of his having fallen with them in the horizontal position, instead of placing them closely to his sides. The concussion on falling into the water had sufficed to produce the accident. (Smith's For. Med. p. 228.) Here, then, we have a proof that even the mechanical resistance offered by water alone may give rise to marks of very violent injury on the person. Extravasation of blood may take place into the cavities from this cause. Dr. N. Chevers has informed me that he assisted in examining the body of a sailor who fell into the water, with his head downwards; and it was found that there was an extravasation of blood in the head, beneath the arachnoid membrane.

It has been observed, with respect to superficial marks of violence, that bruises or contusions are not always visible on the bodies of the drowned, when they are first removed from water. This may be owing to the skin having abundantly imbibed water,—the colour of the ecchymosis being thereby concealed. After a short exposure to air, the water evaporates, and the bruise or contusion becomes visible. The great point with regard to all marks of violence on the drowned, is to throw light upon the questions: 1, whether drowning was really the cause of death; and 2, whether, if so, the act was the result of accident, suicide, or homicide. This last question does not concern a medical witness so much as the jury, who will determine it from the facts proved before them.

There is one case of rare occurrence, in which a practitioner would be apt to be misled by trusting to appearances found on the drowned. If a dead body were removed from water with a deep ecchymosed circle round the neck, evidently produced by a cord or ligature, but no traces of which could be found, it is not improbable that a suspicion would be at once raised, that the deceased had been murdered by strangulation, and the body afterwards thrown into water. An accident occurred a few years since in which a gentleman and his wife were thrown into the water by the overturning of a small boat. The lady was drowned. On an examination of the body, subsequently made, a livid circle was found round her neck, as if she had been strangled. She had evidently died by drowning, but the mark had been produced by the string of a cloak which she wore at the time of the accident. In her struggles to reach the boat, it is presumed that the tide
had drifted the cloak in an opposite direction, and thus produced the appearance of strangulation. It is not improbable that this accelerated death. Barzelotti mentions the case of a man who was drowned in the Po, while being escorted along the banks of the river, as a prisoner, by a party of soldiers. The man attempted to escape and was drowned. Besides the ordinary marks of drowning, there was a deep livid circle, extending completely round the neck, and immediately below this, another mark but paler in colour. The skin over the trachea was ecchymosed. It was supposed that the deceased had been strangled by the soldiers and his body thrown into the water, but from the appearance of the marks, and other circumstances, Barzelotti gave it as his opinion that they were produced by the collar of a coarse linen shirt which had been tightly buttoned around the man's neck—the collar had retracted from the imbibition of water, and had thus caused the appearance of strangulation, like any other ligature. (Questioni di Medicina Legale, i. 329. For another case, see Henke's Zeitschrift, 1840, i. 126, Erg. H.) The following case was communicated to me as having occurred during the heavy floods in the winter of 1839. A man was carried away and drowned in attempting to ford a swollen stream. When the body was found, it had been so placed by the current, that the forepart of the neck was locked against the stump of a tree, giving rise to an ecchymosed patch like that which is commonly produced by manual strangulation. [For the report of a case, in which there was much violence to the neck, see Henke's Zeitschrift, 1842, i. 258, Erg. H.]

It might be said that in cases of this description circumstantial evidence would commonly show how the mark had originated. In admitting the truth of this observation, we must remember that circumstances, as matters of proof, do not always present themselves to our notice, or occur to our judgment, at the precise time that the law stands most in need of them. While, then, we use great caution in drawing an inference when there are such strong grounds for suspicion, we should not neglect to examine carefully the most trivial appearances. In a remarkable case of murder, in which the body of the deceased was discovered in a mill-stream, there was only one slight ecchymosed depression in the fore-part of the neck, as if from a finger. The surgeon suspected from this that the deceased had been strangled. The marks of drowning in the body were wanting; and the suspicion of the real cause of death was afterwards confirmed by the confession of the criminal.

Accidental fractures in the drowned.—Fractures are not often met with in the drowned as the result of accident during or after the act of submersion. Certain fractures likely to be followed by immediate death may forbid the supposition of their having occurred after the act of submersion, and a careful examination of the body
may show that they were not likely to have arisen from accident at or about the time of submersion. This point was raised in the case of Reg. v. Kettleband (Nottingham Winter Ass. 1843), where the prisoner was charged with the murder of his son, a boy aged ten years. The deceased was found dead in a pond soon after he had been seen healthy and well. An inquest was held, and as usual no inspection of the body was required by the coroner, and the jury were directed to return a verdict of "found drowned." An inspection was, however, subsequently made. The neck was observed to be very loose, and on further examination the processus dentatus was found to be separated from the atlas, and the ligaments were ruptured! The three medical witnesses who gave evidence at the trial, deposed that this displacement had caused death by compressing the spinal marrow,—that the injury had occurred during life,—that it was not likely to have been caused by accident from a fall into the water, as there was no mark of a bruise about the head, and the pond was proved to be small, with a soft muddy bottom. All agreed that such an injury was not likely to have arisen from a blow or a fall under any circumstances, because it required for its production that the body should be fixed, and the head forcibly rotated on the trunk. It was in itself sufficient to account for immediate death, and it could not occur by accident after death from any other cause. Hence it was inferred,—1, that death could not have been caused by drowning; 2, that it had resulted from the compression of the spinal marrow, by displacement of the second vertebra; and, 3dly, that this injury must have been intentionally produced by some person. Circumstances fixed the crime on the prisoner, and the jury returned a verdict of manslaughter; although the nature of the injury, admitting that it was not the result of accident, proved that the prisoner must have acted with a most cool and deliberate intention to destroy life! This case furnishes a serious commentary on the practice of certain coroners, in denying the necessity for an inspection, and in directing what is called an open verdict of "found drowned," when a body is taken out of water!

It is an important medico-legal question, whether fractures of the cervical vertebra can occur from accident alone, about the time of drowning. In the above case, the medical witnesses had probably good reasons for denying that the injury was accidental, although such an opinion cannot always be expressed merely from the absence of marks of violence on the head. Mr. South quotes the case of a man who threw himself into a river to bathe from a height of seven or eight feet, the water being only three feet deep. He rose to the surface, but fell back senseless. When he recovered his consciousness, the account he gave of the accident was, that he felt his hands touch the bottom of the river, but to save his head drew it violently back, upon which he lost all consciousness. He died in about ten hours, and on examination the
back of the neck was much ecchymosed—the interspaces of the muscles were gorged, and the vertebral canal filled with blood. The body of the fifth cervical vertebra was broken across about the middle of its depth, and the two pieces were completely separated from the lateral parts. As there was no mark of contusion or dirt on the head, Reveillon, who reports the case, believes that the fracture arose from muscular action, and not from a blow received by striking the bottom: but this is doubtful. In another instance related by Mr. South, a sailor jumped headlong into the sea to bathe, a sail being spread three feet below the surface. He immediately became motionless, and died in forty-eight hours. The fourth and fifth cervical vertebrae were found extensively fractured, and the spinal marrow was crushed and lacerated. (Chelius's Surgery, Part vi. Fractures.) In this case the fracture must have resulted from contact with the water or the sail; but as the latter was freely floating, this would be a yielding medium; hence this serious injury may occur accidentally in cases in which we might not be prepared to look for it. (For an important medico-legal case, involving many questions connected with marks of violence on the drowned, see Ann. d'Hyg. 1839, ii. 195.)

Was the drowning the result of homicide, suicide, or accident?—Although the question, whether the act of drowning was the result of suicide or murder, properly falls within the province of a jury, there are certain points in relation to it which here require to be noticed by a medical witness. In the first place, it is not to be imagined that an examination of the body will develop any differences in either of the three supposed kinds of death. So far as the phenomena of drowning are concerned, they are the same; and are accompanied by the same appearances after death in each case. In drowning which is accidental or suicidal, it is not common, as it has already been observed, to meet with marks of violence on the person, except such as are purely of accidental origin, and have commonly been produced after death. In accidental drowning, this is almost a constant rule: but if the individual has fallen from any height, his person may be injured in the fall either by projecting bodies on the banks of a river or canal, or by mere concussion on the water, allowance for either of which we must be prepared to make, according to the situation of the spot from which the party is supposed to have fallen.

It is calculated that drowning is the cause of death in nearly one-half of all suicides; but this of course will vary according to localities. In suicidal drowning we have a difficulty to encounter which we do not meet with in that which is accidental. A man may have attempted suicide by some other means, previously to precipitating himself in the water: thus, then, besides the accidental violence of accidental drowning, we may meet with violence
on the person evidently indicating wilful perpetration. What is
the nature of this violence? Is it to be defined? Can it always
be distinguished from that which is positively homicidal? The
answers to these questions must depend on the circumstances
proved in each case.

A man may attempt to hang or to strangle himself, and not
succeeding, may afterwards drown himself. Here we should
find a mark on the neck, which many would at once deem pre-
sumptive of murder. If the suicide had neglected to remove the
cord from his neck, death would be considered still more clearly
to have arisen from murder. A suicide may produce a severe
penetrating wound on his person, and afterwards drown himself.
In such a case, it is not even the necessarily mortal nature of the
injury which would allow us to come to a prompt decision; for
although a man labouring, for instance, under a penetrating
wound of the heart, or a deeply incised wound of the neck, is
not likely to run far, or to require to drown himself in order to
die, yet instances are on record where such wounds have been
inflicted on the brink of the water, and even at the moment of
precipitation, to ensure a speedy death. The same remark also
applies where a gun-shot wound of great extent exists on the
body, as when the abdomen, chest, or head, has been traversed
by a pistol-bullet: for suicides have been known to shoot them-

selves immediately before throwing themselves into water. But
of all cases, perhaps, that of the evidence of poisoning, by the
discovery of poison in the body of a drowned person, is cal-
culated to produce the greatest ambiguity; since it is obvious
that the deceased may have taken poison, and, before its fatal
operation on the system, have had time to complete the act of
suicide by drowning. A case of this kind has been communi-
cated to me by Dr. Barker, of Bedford. A young lady com-
mitted suicide by drowning, and on examining the stomach,
arsenic was found therein, which she had swallowed previously
to throwing herself into the water. These difficulties, it is true,
are commonly removed by circumstantial evidence; but this is
wholly collateral to the duties of a medical witness. He must
treat the case as one which is purely medical; for when the
Court puts a question to him relative to the possibility of any of
the above coincidences existing, he is obliged to give an abstract
answer either in the affirmative or negative. If his opinion
were founded wholly on circumstantial evidence, and not on
medical principles, it would be rejected, since it is for the jury
alone to connect the circumstantial with the medical evidence.

Are there no rules, then, it may be asked, to distinguish suicidal
from homicidal drowning? Medically speaking, the drowning
is presumptively suicidal when there are no marks of violence;
and it is presumptively homicidal when severe vital injuries, of a
more or less speedily mortal or dangerous character, and not
likely to have had an accidental origin, are met with. The latter presumption is founded on the fact, that murder by drowning is extremely rare without previous violence being used by the murderer. The homicide generally leads to his own detection by inflicting more violence than is necessary for the destruction of his victim. In all these cases, when the facts are unknown, there is a rule which, it appears to me, the examiner ought to follow, and that is, never to pronounce a positive opinion in favour of homicidal drowning from violence on the person of the deceased, unless the violence be so situated on the body that it could not have been self-inflicted, and unless it be of a nature to have destroyed life speedily.

*Drowning in shallow water.*—Homicide has been sometimes presumed from the peculiar circumstances under which the body has been discovered. Thus, for instance, it has been a debated question, whether a person intent on suicide can actually drown himself in shallow water. This question has been long since settled in the affirmative by the occurrence of some well-authenticated cases: it appears to have been raised originally on the theoretical view, that the resolution of a suicide would fail him in such a situation, and that having the means of escape, he would lose no time in extricating himself. It need hardly be stated that the mere immersion of the mouth in water not more than a few inches deep, will produce all the phenomena of death by drowning, with the exception that little or no water would probably be found in the stomach. Devergie mentions an instance which occurred in May 1833, where a man was found drowned in a small stream, his face towards the ground, and his head just covered by the water, which was not more than a foot in depth. On dissection, there were all the appearances of drowning present, and a large quantity of sand and gravel was found occupying the trachea and bronchial ramifications. (Op. cit. ii. 332.) A case is mentioned by Dr. Smith, in which a woman committed suicide by breaking a hole in the ice of a pond, during the winter, and thrusting her head into the water, the rest of her body being out. In May 1837, a man was found dead near Mitcham in Surrey. He was discovered lying on his face in a small stream of water only six inches deep. The water was so shallow that it did not cover the deceased's body or his head. There was clear evidence that this was a case of suicidal drowning. In November 1855, a man was found drowned in a water-cistern, which at the time had in it only fourteen inches of water.

The discovery of bodies under these circumstances does not necessarily establish that the act was suicidal. It is quite possible that one or more murderers may hold a person's head in such a position sufficiently long to destroy life; but as the party might be capable of making resistance, we ought then to find marks of
violence on the body. So, again, such a position is by no means incompatible with accidental drowning; and on this it may happen that a medical practitioner will be called to express an opinion. A man, in a state of deep intoxication, or when suddenly attacked by syncope, epilepsy, or apoplexy, may fall with his face in a gutter, ditch, or small pool of water; he may die in this position, not having the power to extricate himself (ante, p. 749, also p. 756.) Even violence on his person must not be too hastily construed into proofs of murder. Not long since, a case of this description gave rise to a trial for murder in one of our midland counties. A man was found dead with his face in some melted snow; and there were several severe contusions on his body. The evidence showed that, after a quarrel, he had left a neighbouring inn deeply intoxicated; and it was rendered extremely probable, that he had perished accidentally on his way home. There was no reason to suppose that he had been murdered. Infants, from mere helplessness, may be drowned under similar circumstances.

**Drowning from partial immersion.**—There is no doubt that murder by drowning may be perpetrated without the whole of the body being immersed in water. A case of this kind, which was the subject of a criminal trial, was referred to me by Mr. Aldred, of Norwich, in March 1841. The case was tried at the Norwich Lent Assizes, of that year (The Queen v. Yaxley), and the prisoner was convicted. It appears that the mode in which the prisoner destroyed her infant child, was by immersing its head for a few minutes in a pail of water. She removed it before it was quite dead, but it soon died with slight convulsive motions of the limbs. The case was rendered obscure by the fact that the whole of the body had evidently not been immersed; and the only conceivable means of drowning were in a small duck-pond adjoining the house, which was covered with weeds; but no weed was found in the stomach of the child, although a quantity of water was there present. In April 1854, a case occurred in London, in which a woman was charged with causing the death of a child by drowning it. The child was found dead with its face in a basin of dirty water. The prisoner had placed the child in this position, and had then locked the door. The death of a child under these singular circumstances is, however, quite compatible with accident. Mr. Tubbs has communicated to me the following case, which fell under his notice in April 1848. He was called to see a child at 18 months, which was stated to be dying. On his arrival at the cottage, he found it dead: the skin was cold, and the countenance calm and pale, with the exception of a livid discoloration in the centre of each cheek. The eye-lids, as well as the mouth, were half open. The pupils were largely dilated. A frothy mucus, tinged with blood, was escaping from the mouth and nostrils. The tongue was swollen,
and protruded forwards. The mother of the infant, a respectable woman, gave the following account: — She was washing in one room, while the child was in an adjoining room, the door between the rooms being kept open by a pail half full of water. She went out of the house for about two minutes, and on her return she found the child with its head downwards in the pail of water, the heels and part of the body hanging over the side of the pail. She snatched it out and tried to revive it, but without effect. There was no reason to doubt the truth of her statement, and at the inquest the jury returned a verdict of accidental death. The helplessness of an infant at this age, and the rapidity with which asphyxia supervenes, sufficiently account for its death under these circumstances. A case occurred in London, in 1841, in which a drunken man was drowned by falling on the bank of the Surrey Canal, with his head partly in the water, while the greater part of his body lay on the bank out of the water. It was by partial immersion that the Italian boy, Carlo Ferrari, was destroyed some years since, by Bishop and Williams, who afterwards attempted to sell the body for the purposes of dissection. The murderers first intoxicated the deceased, and then suspended him by the heels in a well, so that his mouth was but a few inches below the level of the water. A medical man, therefore, must not allow himself to be deceived respecting the cause of death on finding that the whole of the body has not been immersed. In this form of murder, when the inspection is recent, water with or without weeds or other foreign matters may be found in the ear-passages.

Ligatures on the hands and feet. — When a drowned subject is removed from water with the hands and feet bound by cords, it is usually considered that we have therein strong presumptive evidence of homicide; but numerous cases are recorded in which suicides have actually bound themselves in this manner before throwing themselves into water, probably for the express purpose of preventing any chance of their escaping death. In July 1832, the body of a full-grown man was removed from the Seine, his neck, legs, and hands being secured together by a cord furnished with slip-knots. There was no doubt that he had died by drowning, and that the act was one of deliberate suicide, the cord being so placed on his body that an individual could easily place it on himself. In this case there was no great degree of ecchymosis produced by the cord; nor is it likely that there should have been, when it was arranged by a suicide, since his object would be merely that of rendering himself helpless by securing his arms and legs. This he would doubtless accomplish without giving himself much pain. If the marks bear the evidence of violent constriction, especially on both wrists or on the fore part of the neck, the presumption of murder becomes very strong. In a case of this kind, it would be obviously of great importance to determine
whether the deceased had really died by drowning or not; since, if his death had not been due to drowning, the fact of his body, so bound, being discovered in water, would furnish the strongest possible evidence of murder. (Ann. d'Hyg. 1833, i. 207.)

Weights attached to the body.—If a body be taken out of water with heavy weights attached to it, the question of accident, as in the former case, is done away with. It must be either homicide or suicide; and doubtless many would be apt to suspect that it was a case of murder. Several instances have, however, occurred, where persons have committed suicide by drowning, and heavy weights have been found attached to their feet and hands, or in or about the dress.

Age.—Another question which may be considered is this:—Does the age of a drowned subject rebut the presumption of suicide, even when there is no other ground for suspecting murder? In the case of an infant, this question must assuredly be answered in the affirmative. If the body of a new-born child be discovered drowned in water, the case must be one of accident or murder. Murder is generally presumed by our law on the clear evidence that drowning was the cause of death; it is then for the accused party (commonly the mother) to satisfy the Court that the drowning was accidental. The discovery of any wounds, or other marks of wilful violence, would altogether do away with the presumption of accident. It must, however, be proved that the child died from drowning, since a woman may merely have placed its dead body in water for the purpose of concealment.

But we cannot so easily fix the age at which the suspicion of suicide would cease to be rebutted thereby. The question might arise on the discovery of the drowned body of a child not more than three or four years of age; and in this case suicide would be highly improbable. Such young subjects are often drowned by accident, but then there are facts usually forthcoming which remove all the difficulties from the investigation. The youngest age of suicide by drowning which I have met with was in a boy of 13; in two other cases of girls aged 13 and even 11, suicide by drowning was attempted. (Ann. d'Hyg. 1836, ii. 402.) After 13, suicide by drowning has been known to have been committed at every period of life up to the age of 86. Suicide by drowning is, however, almost as rare in advanced age as in infancy.
HANGING.

CHAPTER LIX.

Cause of death. Asphyxia.—By hanging we are to understand that kind of death in which the body is wholly or partially suspended by the neck, and the constricting force is the weight of the body itself; while, in strangulation, the constricting force is due to some other cause. In both cases death commonly results from asphyxia (ante, p. 720), although this must depend in a great measure upon the position of the ligature on the neck, as well as on the degree of pressure produced. If the cord be loose, or applied to the upper part of the neck, a small quantity of air may still reach the lungs: and then the cerebral circulation becomes interrupted by the compression of the great vessels of the neck. In this case apoplexy of the congestive kind is induced, and operates as the immediate cause of death. It is easy to conceive that there may be a mixed condition of asphyxia and apoplexy, and according to the observations of Professors Casper and Remer this is actually met with in a great number of instances. The following tables represent the results at which they have arrived from the examination of a large number of cases:—

It has been observed in the execution of criminals, that death does not always ensue within the same period of time; and we may probably best explain this fact by a reference to the greater or less degree of constriction produced by the ligature. If the rope should press upon the larynx or above this organ, the occlusion of the air-passages will not be so complete as if it pressed upon the trachea immediately below the cricoid cartilage. A slight degree of respiration might, in the former case, continue for a short interval, by which the life of a person would be prolonged; while in the latter, death would be immediate. If the trachea be in part ossified, the pressure of the cord is less perfect, and death will then take place more slowly. It has been supposed that the immediate cause of the stoppage of respiration was a pressure produced by the cord on the nerves of the neck; but it must be considered as very improbable that, under the circumstances in which hanging generally takes place, the cord should exert any pressure on the nerves sufficient to produce death. In the greater number of cases of suicidal hanging, which are commonly unattended with much violence, the pressure on these nerves cannot obviously exist; and in violent hanging, the projection of the anterior parts of the neck must suffice to prevent these slender nervous filaments from becoming exposed to such a degree of compression as directly to impede the exercise of their functions.

There is an occasional cause of death in hanging, which appears to have been first brought to the notice of the profession by Louis. Having remarked that, in public executions, death sometimes took place with great rapidity, and in other cases more slowly, he was led to inquire into the circumstances. He found that in the cases of rapid death, the executioner was in the habit of giving a violent rotatory motion to the body of the criminal at the moment it was turned off, whereby a displacement of the dentiform process of the second cervical vertebra took place, so that the spinal marrow became suddenly compressed. This cause of death must be extremely rare: as a general rule it is only likely to be observed in very corpulent subjects, when a long fall is given to the cord, and when much violence has been at the same time employed by the executioner. It is seldom met with in subjects criminally executed; and in cases of suicidal hanging it is so rare, that Devergie found the ligaments between the first and second cervical vertebrae ruptured only once in fifty-two cases. M. de la Fosse considers, from the observations which he has made on the subject, that, in violent hanging, the dentiform process of the second cervical vertebra is much more likely to be fractured than to become displaced, and he found this in the case of an executed criminal. On an examination of the body of this subject, he discovered that the two first cervical vertebrae had been completely separated from the remainder of the spine.
column by the rupture of the intervertebral substance, and that they were firmly attached by their ligaments to the occipital bone. The dentiform process and body of the second vertebra were detached from the bony ring, but were still connected as usual with the anterior arch of the atlas. The spinal marrow had become compressed by the fractured portions of the vertebrae. Probably further observations would show that the injury to the spine is not always of the same nature, and that fractures of the vertebrae are really more frequent than simple luxations of the dentiform process: in the meantime, we must admit that such severe injuries may occur in hanging, and that when they do occur, death must be very sudden. But death may proceed from mere effusion of blood on the spinal membranes (sheath), thereby giving rise to fatal compression. This is likely to happen when the head falls, or is bent suddenly backwards, so that the weight of the body is supported on the back of the neck. See a case of this kind by Mr. Campbell de Morgan (Post, p. 792.)

Rapidity of death.—Death from hanging appears to take place very rapidly, and without causing any suffering to the individual. It is observed, that in those who are criminally executed, there are often violent convulsions of the limbs and trunk. There is no reason, however, to believe that the individual suffers pain, any more than in the convulsions of an epileptic fit. On recovery there is an entire loss of consciousness of pain in both cases. The circulation of dark-coloured blood through the brain and spinal cord, after the stoppage of respiration, may account for these effects. Efforts to inspire are made for from one to two minutes after the closure or compression of the wind-pipe. The diaphragm and intercostal muscles act spasmodically, but no air enters the lungs, and it is probable that, in the act of hanging, part of the air contained in the organs is convulsively expelled. When the suspension of the body has only continued a few minutes, it has often been found impossible to restore life; and indeed the period at which resuscitation may take place will vary in different subjects according to circumstances. Supposing the hanging to be unattended with violence to parts about the neck, it is possible that some individuals might be resuscitated after five minutes’ suspension or longer. Others, again, may not be restored even when they are cut down immediately after suspension,—a fact which depends probably on the different degrees to which asphyxia or apoplexy may have extended.

Death from the secondary effects.—It by no means follows that because we have succeeded in restoring the respiratory process, the individual is safe. Death often takes place by a fatal relapse at various periods after the accident. A case of this description has been published by Sir B. Brodie. A boy, aged 17, was found hanging. When cut down he was insensible, his face livid, his lips were of a dark purple colour, pulse not perceptible, pupils dilated
DEATH FROM SECONDARY EFFECTS.

and motionless. Artificial respiration was used, and in a quarter of an hour the diaphragm began to act. He breathed at irregular intervals with stertor, and with a rattling noise in the throat. The pulse became perceptible but often flagging, and the surface of the body was cold. The countenance was still livid, but the pulse and breathing improved. At the end of another hour an attempt was unsuccessfully made to take some blood from the arm, and the patient was placed in a warm bath. The breathing was stertorous through the night, and in the morning twelve ounces of blood were taken from the arm; but there was no relief. He continued insensible, and cold on the surface: there was frothing at the mouth, and he died twenty-four hours after he was cut down. The body was carefully examined. The vessels of the brain were very turgid with blood: this was the only morbid appearance. In another instance, a labouring man who had hanged himself was cut down in a state of insensibility. He lay for a considerable time breathing with apoplectic stertor, but eventually recovered. (Lectures on Pathology, 72.) Dr. Shearman has reported in the Lancet (Jan. 6, 1844), a case in which a powerful athletic man, who had been committed to prison for theft, hung himself. He was found apparently dead, hanging by his own handkerchief. He was cut down, and seen by Dr. S. half an hour after the occurrence. The man was then apparently lifeless; he neither breathed nor moved, nor had any perceptible circulation. The face and neck were much swollen and livid, and the ecchymosed mark of the cord was immediately below the thyroid cartilage: the fingers were bent, and the hands nearly clenched. His head was raised, the windows were thrown open, and blood abstracted from the arm, which was put into hot water in order to increase the flow. In a few minutes the man began to breathe:—the bleeding was allowed to continue until the pulse was felt at the wrist, and the pupil contracted completely on the application of a lighted candle. The breathing was stertorous. Brandy and water were injected into the stomach, and warmth was applied to the extremities. In the course of a few hours he rallied very much; his pulse had become firmer and quicker (130), his head was hot; he was very restless, unmanageable, and violently convulsed in the arms and legs. Shortly before death he was calm, and spoke several times. He suddenly became exhausted, and died nineteen hours after he was found hanging. This was probably a mixed case of asphyxia and apoplexy. The medical treatment appears to have been very proper. The unsuccessful result may perhaps be ascribed to the injury sustained by the cerebral circulation from constriction of the neck. In hanging, as well as in drowning, therefore, a person may in the first instance recover, but subsequently die in spite of the best medical treatment, probably from the depressing effects produced on the nervous and muscular systems by the circulation.
of dark-coloured blood. A case in illustration of this point has been reported by Dr. B. W. Richardson. (Med. Times and Gaz., Dec. 17, 1858, p. 639.) The man died on the second day after he was cut down. On inspection, the brain was found greatly congested, and there was effusion of serum under the (arachnoid) membrane. The lungs and heart were congested, and a solid fibrinous deposit was found in the right ventricle.

Treatment.—Artificial respiration, cold affusion when the skin is warm, with the vapour of ammonia and other stimuli, may be employed on these occasions. If there should be much cerebral congestion on recovery, venesection may be cautiously resorted to. The introduction of oxygen into the lungs, or the application of electricity or electro-magnetism in the course of the spine, might be attended with benefit; but much will depend, as in drowning, upon the time at which assistance is rendered after the body has been cut down. The following case of recovery, in which, however, asphyxia was not complete, is reported in the Lancet for Nov. 1839. A robust woman, aged 33, hung herself while slightly intoxicated. She was missed about ten minutes before she was found suspended to a bedstead, but how long she had been thus hanging it was impossible to determine. Medical assistance was rendered to her in about ten minutes after she had been cut down. She was then quite insensible, her respiration slow and laborious, and her pulse barely perceptible. The countenance was pale,—there was no lividity; the lower jaw was depressed, the extremities were moderately warm, and the hands convulsively clenched,—the pupils were somewhat dilated, and barely susceptible of the stimulus of light. A dusky red mark, of a quarter of an inch in breadth, was distinctly observed encircling the upper part of the neck, forming an angle over the ramus of the jaw on the right side, where the knot of the ligature (a silk handkerchief) had rested; and in consequence of this the constriction was incomplete. The patient was twice copiously bled, mustard poultices were applied to the calves of the legs, hot water to the feet, and cold applications to the head. After thirty-two ounces of blood had been abstracted, in half an hour the breathing became stertorous, the pupils fully dilated, the lower jaw fell further, the sphincters became relaxed, and the patient appeared to be rapidly sinking. Ammoniacal liniment was rubbed on the chest, and the woman so far recovered in an hour as to be able to swallow; but although she was conscious of pain, she remained comatose until the evening, when she became perfectly sensible of surrounding objects. This was evidently a case of imperfect suspension, in which, owing to respiration still continuing, there was every hope of recovery. The cerebral circulation had here become disordered.

In the following case, which occurred to Mr. Noyce, cold affusion speedily resuscitated the individual. A man had been hanging
about two or three minutes when he was cut down, and in four or five minutes afterwards he was seen by Mr. Noyce. He had then ceased to breathe: his features were pallid, and the membranes of his eyes (conjunctivæ) were injected with blood. The heart's action continued, although feebly; the pulse being about 80, and very weak. Artificial respiration was tried without any benefit, when cold affusion was resorted to. This, after a very short time, led to the complete establishment of respiration: at each affusion there was a deep inspiration. The man was bled to sixteen ounces, and he soon recovered his consciousness. (Med. Gaz. xxxvii. 75.) When great cerebral congestion is produced, as by a close constriction of the throat, copious bleeding will generally be found beneficial. Dr. Chevers mentions a case in which some Thugs, quite unintentionally, saved the life of a person whom they had strangled, by cutting his throat. A man travelling through Tirhoot fell in with a gang of Thugs who strangled him. He became unconscious. On recovering his senses, he found that his throat had been cut, and that a fellow-traveller lay strangled to death by his side. The wound on the throat was properly treated, and the man recovered in six weeks. He was able to give a description of the gang, which subsequently led to the apprehension of four, who were sentenced to death. As Dr. Chevers remarks, it can scarcely be doubted that the violent measure of cutting the man's throat, effectually relieved the vessels of the brain of any undue congestion which the throttling may have produced. (Med. Jour. for India, 405.)

These cases bear out the views long since published by Sir B. Brodie; namely, that after respiration has ceased, the heart still continues to act, and to circulate dark-coloured blood, for a period of three or four minutes, to the brain and other parts of the system. The exact period of time during which this circulation continues will, however, depend on the age, sex, and strength of the individual. It is on this ground that there is great hope of restoring the individual by artificial respiration. The dark-coloured blood acts as a poison, and slowly destroys life. (Lectures on Pathology, &c. 66-70.) The moment of somatic death is that at which the action of the heart ceases, and this may be subject to great variation. The action of the heart was observed in one case of criminal hanging to continue for so long a period as nine minutes and a half after suspension. A criminal was executed for murder at Albany, U. S. The execution took place in a passage of the prison, so that the feet of the criminal were only twelve inches from the ground. The pulse was felt by a surgeon on each side. It is stated that in the fifth minute there were one hundred and twenty-eight pulsations. (Med. Times and Gazette, July 1, 1854.)

In the after-treatment, it is advisable that blood should be only sparingly abstracted, to relieve any cerebral congestion; because
the vital powers are much reduced under the circumstances. Convulsions, and even paralysis, have been observed to precede recovery in experiments on animals.

Period at which death takes place.—We learn from those who have been resuscitated, as well as from experiments performed by individuals upon themselves, that asphyxia comes on in the most insidious manner in death from hanging; and that the slightest constriction of the trachea will speedily produce insensibility. (Devergie, ii. 370.) The symptoms of which resuscitated persons have been conscious, were a ringing in the ears, a flash of light before the eyes, then darkness and stupor. The only profitable inference, in a medico-legal view, which can be drawn from observations of this kind, is, that asphyxia—indicated by insensibility, unconsciousness, and entire loss of muscular power (apparent death)—is not only very rapidly induced, but that it supervenes under circumstances in which it would not be generally expected to occur, i.e. when the body of a person is in great part supported. M. Fleichmann found that a cord might be placed round the neck between the chin and os hyoideum, and tightened either laterally or posteriorly, without perceptibly interrupting respiration: but while the respiratory process was thus carried on, the face became red, the eyes prominent, and the head felt hot. These symptoms were followed by a sense of weight, a feeling of incipient stupefaction, and a hissing noise in the ears. On the occurrence of this last symptom, the experiment should be discontinued, or the consequences may be serious. The first experiment lasted two minutes; but in the second, owing to the cord by its pressure more completely interrupting respiration, the noise in the ears appeared in half a minute. When the pressure was applied on the trachea, the effect was instantaneous, but when on the cricoid cartilage it was not immediate. When it was applied between the os hyoideum and the thyroid cartilage, or on the os hyoideum itself, the period during which an individual could respire was extremely short; and this result was more striking when the act of expiration was performed at the moment of applying the pressure. The death of Scott, the American diver, in January 1840, shows how very readily asphyxia may be induced by slight compression of the throat, even when a person might be supposed to have both the knowledge and the power to save himself. This man was in the habit of making public experiments on hanging, and had frequently before gone through them without danger: but on this occasion, it is probable that a slight shifting of the ligature, from under the jaw-bone, caused so much compression on the throat between the chin and larynx, as speedily to produce asphyxia. No attempt was made to save him until it was too late, and he was not brought to an hospital until thirty-three minutes had elapsed. He was allowed to hang thirteen minutes,—the spectators think—
HANGING. APPEARANCES AFTER DEATH.

ing that the deceased was only prolonging the experiment for their gratification! The very insidious and painless manner in which an individual who is suspended, passes from life to death, is well illustrated in a report of the case of Hornshaw, published by Dr. Chowne. (Lancet, April 17, 1847, 404.) This man was on three occasions resuscitated from hanging,—a feat which, like Scott, he had performed for public gratification. He stated that he lost his senses almost at once; that it seemed as if he could not get his breath, and that some great weight was attached to his feet; he felt that he could not move his hands or legs to save himself, and that the power of thinking was gone. These effects must be ascribed to the circulation of the dark-coloured blood through the brain. It is not improbable that many persons have thus lost their lives by privately attempting these experiments, and their cases have been wrongly set down as cases of suicide. There is, I think, no doubt that boys have thus frequently but unintentionally destroyed themselves from a strange principle of imitation or curiosity. The following is one among many cases of this kind. In August, 1844, a boy, aged fourteen, witnessed an execution at Nottingham, and he was afterwards heard to say he should like to know how hanging felt. On the same afternoon, he was found suspended by a cord from a tree, quite dead. From the circumstances there could be no doubt that he had been experimenting on the theory and practice of hanging, and that he did not really intend to destroy himself.

Appearances after death.—The following external characters of the body are laid down as indicative of hanging by most medical writers. Lividity and swelling of the face, especially of the lips, which appear distorted;—the eyelids are swollen, and of a bluish colour;—the eyes red, projecting forwards, and sometimes partially forced out of the orbital cavities;—the tongue enlarged, livid, and either compressed between the teeth or frequently protruded;—the lower jaw is retracted, and a sanguineous froth sometimes exists about the lips and nostrils. There is a deep and ecchymosed impression around the neck, indicating the course of the cord, the skin being occasionally excoriated;—laceration of the muscles and ligaments in the hyoidal region;—laceration or contusion of the larynx, or of the upper part of the trachea. There are also, commonly, circumscribed patches of ecchymosis, varying in extent, about the upper part of the trunk and the upper and lower extremities, with a deep livid discoloration of the hands. The fingers are generally much contracted or firmly clenched, and the hands and nails are livid. The urine and feces are sometimes involuntarily expelled at the moment of death. Internally, we meet with the appearances described under the head of asphyxia, i.e. engorgement of the lungs and venous system generally, with dark-coloured blood. The right side of the heart, and the great vessels connected with
it, are also commonly distended with blood. But when the inspection has been delayed for several days, this distention may not always be observed. The mucous membrane of the wind-pipe is more or less congested, and is sometimes covered with a bloody mucous froth. This may be owing to imperfectly obstructed respiration, and spasmodic efforts at breathing. The vessels of the brain are commonly found congested; and, in some rare instances, it is said extravasation of blood has been met with on the membranes and in the substance of the organ. Extravasation of blood is, however, so rare, that Remer found this appearance described only once among one hundred and one cases; and in one hundred and six cases, recorded by Casper, it was not found in a single instance. In one case of death from hanging, Sir B. Brodie found a large extravasation of blood in the substance of the brain; and he refers to another case, in which there was a considerable extravasation between the membranes. (Lectures on Pathology, 58.) The venous congestion of the cerebral vessels is rarely greater than in other cases of asphyxia, and is probably dependent on the degree to which the lungs have become engorged. In most instances there is increased vascularity of the substance of the brain, so that, on making a section of the hemispheres, a greater number of bloody points than usual will appear. The kidneys have been found much congested. A more important circumstance has been noticed by Dr. Yelloly, namely, that in examining the stomachs of five criminals who had been hanged, he found great congestion in all; while there was blood extravasated and coagulated upon the mucous membrane in two. Such an appearance might, it is obvious, be attributed in a suspicious case to the action of some irritant substance. (See Ann. d'Hyg. 1830, 166; 1835, 208; 1838, 471.) In the case of Good, who was executed for murder a few years since, the stomach was found on inspection to present over its whole surface a well-marked redness, resembling the effect produced by an irritant poison. The redness was especially observed at the pyloric end, where it assumed a somewhat striated character. A drawing representing the appearance of the interior of the stomach is preserved in the Museum Collection of Guy's Hospital. In a case examined by Mr. Stuart, of Azingthorpe, in 1854, the stomach and intestines, especially the inner coat of the former, were much congested and inflamed, as if the man had died from poisoning. The contents of the stomach were analysed, but no poison found. Dr. Chevers, who quotes this case, states that he has more than once verified Dr. Yelloly's observation, and has found the mucous membrane of the stomach much congested in death from hanging. (Medical Jurisprudence for India, p. 397.)

The external appearances have been chiefly derived from the examination of the bodies of executed criminals. Such well-
Marked characters are not generally met with in cases of suicidal hanging; and therefore it will be proper to state what are the principal differences. Thus, the face is sometimes pale,—a condition commonly seen in those cases in which there has been but little obstruction to the cerebral circulation, either from the softness or looseness of the ligature. Esquirol found in one instance, that when the body was examined immediately after death, the face was not livid; but it first began to assume a violet hue in eight or ten hours. He thought that when the cord was left round the neck the face would be livid; but, if removed immediately after suspension, pale. This view is not, however, borne out by observation. The tongue is not always protruded. Devergie found that there was protrusion of this organ only in eleven cases out of twenty-seven. This protrusion was formerly supposed to depend upon the position of the ligature:—thus it was said when this was below the cricoid cartilage the whole of the larynx was drawn upwards, and the tongue carried forwards with it; while, when above the os hyoideum, the tongue was drawn backwards. The protrusion or non-protrusion of the tongue does not depend upon any mechanical effect of this kind, but simply upon congestion; for it is occasionally met with thus protruding in cases of drowning and in other forms of asphyxia. Besides, the protrusion has not been found to have any direct relation to the position of the ligature.

There is another appearance on which a remark may be made, namely, the state of the hands. As a general rule, in violent hanging or strangulation, the hands are clenched. This appearance may not always be found, as it may exist and be destroyed before the body undergoes medical inspection. When the constriction on the neck is produced suddenly and with great violence, we may expect to meet with this appearance. Thus it is found in the cases of executed criminals, and in strangulation attended with great violence (see case by Mr. Bate, post, p. 796), whether the act be due to homicide or suicide. In cases in which the constriction is gradually produced, the clenched state of the hands may not be found. (Cases by Mr. Becke, post, page 796.) Convulsions generally attend violent hanging or strangulation. The influence of these on the attitude or dress may not be apparent, unless the body be sitting or lying.

Mark of the cord or ligature.—The most striking external appearance, however, is the mark produced on the neck by the ligature. The skin is commonly depressed, and sometimes ecchymosed, but rarely throughout its whole extent; it is very frequently free from all traces of ecchymosis, the skin in the depression being then hard, brown, or of a parchment color and consistency; or there may be only a thin line of ecchymosis in the upper or lower border of the depression. The course of the mark is generally oblique, being lower in the fore part than
HANGING. MARKS PRODUCED BY THE CORD.

behind; and it is often interrupted. If the noose should happen to be in front, the mark may be circular, the jaw preventing the ligature from rising upwards in the same degree before, as it commonly does behind. The mark is generally single, but we may meet with it double, as where the ligature has been formed into two circles or loops previously to its application. Its other characters will depend upon the nature of the ligature employed. Thus a large and wide ligature rarely produces ecchymosis,—the mark is wide and superficial; but a small ligature produces a narrow and deep impression, sometimes accompanied with laceration of the cuticle and effusion beneath the skin. From the statistical returns of Devergie and Casper, it would appear that a cord or rope is employed in more than one-half of all the cases of hanging which occur. In other instances various articles of dress were found to have been employed.

Medical jurists have considered it proper to examine into the position of the ligature, as this may sometimes form a question in cases of suspected murder by hanging. The following table will show that in more than two-thirds of all cases of suicidal hanging, the ligature is found encircling the neck between the chin and os hyoides.

Uncchymosed marks or depressions.—It was formerly believed, that the impression produced by the cord was invariably ecchymosed, but more correct observation has shown that this is probably an exception to the general rule. When ecchymosis does exist, it is commonly superficial, and of very slight extent. There is rarely, if ever, effusion of blood in the cellular tissue. Dr. Riecke, of Stuttgart, in his observations on hanging, found only once in thirty cases an extravasation of blood beneath or on both sides of the depression produced by the ligature. The tongue was generally between the teeth, and in most cases wounded by them. He attributed death to stretching of the spinal marrow. (Henke’s Zeitsch. 1840, 27 Erg. H. 332.) In the bodies of individuals who have been criminally executed, it is not unusual to find ecchymosis; but even here it is not always present. In a case which I had an opportunity of examining some years since, there was only a slight trace of ecchymosis in one spot where the knot in the cord had produced contusion. That it should commonly occur in criminal executions is not surprising, considering the violence employed on these occasions; but it has been somewhat too hastily assumed that these appearances in executed
criminals are met with in all cases of death from hanging. This doctrine has been carried so far, that a **livid mark** in the course of the cord has been pronounced to be the best criterion for distinguishing hanging in the living from hanging in the dead body! It will be seen, however, that no reliance can be placed on this appearance. In fifteen cases examined by M. Klein, in twelve examined by M. Esquirol, and in twenty-five cases of suicidal hanging which occurred to M. Devergie (Op. cit. ii. 394), there was no ecchymosis whatever in the course of the ligature. (Annales d'Hyg. 1832, 413; 1842, 146.) Out of six cases, Fleischmann met with only one instance. In three cases of suicidal hanging which I have had an opportunity of examining, no ecchymosis had been produced by the ligature. In all of these instances, the skin, instead of being blue or livid, or presenting effusion of blood in the cellular tissue beneath, was hard and of a **yellow colour**, resembling parchment. It had that appearance which the cutis commonly assumes when the cuticle has been removed from it two or three days: and on dissecting it off, the cellular membrane beneath often appears condensed and of a silvery whiteness. Dr. Chevers states that he has not met with any ecchymosis in the skin along the course of the mark. (Op. cit. p. 406.) In some instances, the mark, instead of being livid or brown, has presented itself simply as a white depression. This has been observed in very fat subjects. The observations of Casper on this point are as follows:—Out of seventy-one cases, there was no ecchymosis produced by the cord in fifty; and thus in two-thirds of the cases examined it was entirely absent. Casper also found that there was no difference in the result, whether the ligature was removed sooner or later after death. Remer considers ecchymosis in the course of the cord to be a frequent appearance in hanging; but Devergie very properly objects to the inference which he has drawn from his cases. (Op. cit. ii. 397.)

The following singular case, which occurred to Dr. Hinze, of Waldenburg, will show that the presence of ecchymosis in the mark does not depend, as E-quirol supposed, on the ligature being left around the neck. A young man in a fit of drunkenness hung himself with a stout cord. In about half an hour afterwards, he was cut down, and attempts made to resuscitate him. It was perceived that the cord had merely produced a superficial impression on the neck, destitute of any appearance of ecchymosis. Signs of returning life began to manifest themselves; the attempts at resuscitation were continued for several hours, but all signs of vital reaction disappeared: and now, when life was about to become again extinct, to the astonishment of those present, the mark on the neck, which had been hitherto colourless, became deeply ecchymosed. On an inspection being made the next day, it was found that this ecchymosis continued:
and that it was owing to a real subcutaneous effusion. From the appearances in the head, it was concluded that the deceased had died from congestive apoplexy.

Other appearances.—Injuries to the muscles and deep-seated parts of the neck are, of course, only likely to be seen when considerable violence has been used in hanging. In one or two instances, the lining membrane of the common carotid artery has been found lacerated. Congestion and tumesfation of the genial organs in either sex, have been set down among the common consequences of hanging,—but many observers have not met with these conditions; and it is doubtful whether, unless the body be examined speedily after suspension, any marked difference would be discovered. A more common sign, perhaps, is the discharge of the spermatic secretion in the male; but according to Casper, it is the mucous secretion of the prostate gland which is thus discharged at the moment at which death takes place. He states that traces of this are met with in from one-third to one-fourth of all cases of death from hanging in the male. It appears to me that very little reliance can be placed upon evidence derivable from this sign, and yet it has sufficed to give rise to a most violent controversy among French medical jurists. (Annales d'Hygiène, 1839, i. 169, 467; ii. 393; 1840, ii. 314.) It is I think clear that unless death from hanging be strongly established by other facts, neither the examination of the linen of the deceased, nor the application of the microscope to the mucous fluid found in the urethra, would be of any practical value in elucidating the question,—at least to the satisfaction of an English jury. M. Donné justly considers evidence of this kind to be a piece of scientific refinement, in which, by attempting to prove too much, we prove nothing. Spermatic fluid may be found in the urethra of a person who has died from natural causes; and Donné has ascertained that the ejaculation of a portion of this fluid into the urethra may even take place in a subject hanged up after death. He has found the fluid in some of these cases to contain living zoosperms. (Cours de Microscopie, 303.)

Summary.—The following may be regarded as a summary of the appearances in death from hanging, when death has really taken place from asphyxia. The countenance is livid, or sometimes pale, the eyes are prominent, the tongue congested and occasionally protruded, the lower jaw retracted:—the skin is covered with patches of cutaneous ecchymosis, the hands are livid and clenched,—an oblique mark is found on the neck,—sometimes presenting traces of ecchymosis: commonly, however, the skin is only brown in colour and hardened. The larynx, trachea, and subjacent muscles, are lacerated, depressed, or discoloured. The vessels of the brain are congested, as well as those of the lungs,
and the right cavities of the heart. A mucous froth is occasionally found in the trachea. These appearances will of course be modified, or they may be altogether absent, when death has taken place from disorder of the cerebral circulation, or from injury to the spinal marrow, either by effusion of blood, fracture, or displacement.

Was death caused by hanging?—When a person is found dead and the body suspended, it may be a question whether death really took place from hanging or not. In investigating a case of this kind, it is necessary to draw a distinction between the external and internal appearances of the body. The former alone can assist us in returning an answer to this question:—the internal appearances of the body can furnish only the general signs of asphyxia, and enable us to say whether any latent cause of death existed or not. The microscopical examination of the blood as contained in the vessels above and below the seat of constriction, has failed to throw any light upon this question. (See Med. Gaz. xxxviii. 1042.) Neither the state of the countenance or skin, nor the position of the tongue, can afford any evidence on the subject of death from hanging.

Evidence from the mark of the cord.—Among the external appearances it is chiefly to the mark produced by the cord on the neck, that medical jurists have looked for the determination of this question. The form, position, and other characters of this mark, having been already described, it will be only necessary to allude to it, as furnishing evidence of life at the time of its production. It has been stated, that so far from being constantly livid or ecchymosed, this condition is, in reality, not seen in more than one half of the cases which occur. But admitting that we find ecchymosis in the course of the ligation, are we always to infer that this must have been applied while the individual was living? The case which occurred to Dr. Hinze (p. 779) proves that the presence of active life is not necessary for the production of an ecchymosis in the mark: and from the experiments of Devergie, it would appear that if a subject be hanged immediately or a short time after death, an ecchymosed mark may be produced by the application of a ligation to the neck. (Op. cit. ii. 408.) If a few hours were suffered to elapse, so that the body had become cold before suspension, no ecchymosis was produced by the ligation. Professor Vrolik, of Amsterdam, found, however, that a slightly livid mark was produced on the neck of a dead body, which had been suspended an hour after death. (Casper, Woch. Feb. 1838.) Hence this condition of the mark in a body found dead, merely indicates either that the deceased must have been hanged while living, or very soon after the breath had left his body. It would be for a jury to decide between these two assumptions; and to consider why, when a person really died from other causes, he should have been
diately after death! (See Ann. d’Hyg. 1842, i. 134.) The circumstance that an ecchymosed mark may be produced by suspending a recently dead subject, bears out the statement of Merzdorff—that it would be in the highest degree difficult, if not utterly impossible, to determine medically, from an inspection of the body, whether a man had been hanged while living, or whether he had been first suffocated, and hanged up immediately after death. In making this admission it is proper to bear in mind, that that which is difficult to a conscientious medical jurist, is often very easily decided by a jury from the general evidence afforded to them.

Sometimes, besides ecchymosis, there are excoriations of the skin in the course of the cord; and these are known to have been produced during life by the effusion of blood. Deverge never met with this appearance in the dead body even when the hanging took place immediately after death. The discovery of effused coagula in or about the spinal column, would render it very probable that the deceased must have been hanged while living. Such marks of violence are, however, rare in cases of hanging; and when they are found, it might be assumed that the effusion and coagulation of blood had been caused by violence offered to the neck immediately after death; but this assumption may be met by the question already suggested, namely, why death by hanging should be simulated in the body of a person who was alleged to have died from another cause!

With regard to the other, or more common kind of mark in suicidal hanging, it can scarcely be said to furnish any evidence in relation to the question which we are here considering. The depression may be hard and brown, although it does not usually acquire this colour until some hours have elapsed after death; for it appears to depend simply upon a desiccation of the portion of skin which has been compressed by the ligature. Sometimes the upper and lower borders only of the depression present a faint line of redness or lividity; and it is worthy of remark, that when the ligature presents any knots or irregularities, those portions of skin which sustain the greatest compression are white, while those which are uncompressed may be found more or less ecchymosed. It is in this way that the form of the ligature is sometimes accurately brought out. It may be remarked of these depressions produced by the cord, that the characters which they present are the same, whether the hanging take place during life or soon after death:—the appearances may be very similar in the two cases.

Effects of hanging on the dead body.—The following are the results of some experiments performed by Casper:—1. The body of a man aged twenty-eight, was suspended an hour after death, by a double cord passed round the neck above the larynx. It was cut down, and examined twenty-four hours afterwards.
SUMMARY OF MEDICAL EVIDENCE.

Between the larynx and os hyoides, there were two parallel depressions about a quarter of an inch deep—the skin having a brown colour with a slight tinge of blue, and a leathery consistency: in certain parts it was slightly exoriated. There was no extravasation of blood beneath, but the muscles which had undergone compression were of a dark purple colour, and the blood-vessels of the neck were congested. The appearance of this subject was such, that any individual unacquainted with the facts, would have supposed, on looking at it, that the person had really been hanged while living. There was nothing to indicate that the hanging had taken place an hour after death. 2. The body of another young man was hanged an hour after death, and an examination was made the following day. The two depressions produced by the double cord were of a yellowish brown colour, without ecchymosis. The skin appeared as if it had been burnt or cut, and felt like parchment. 3. The body of an old man who had died from dropsy, was hanged two hours after death. The impressions presented exactly the same characters as in the preceding case. (Wochenschrift für die G. H. January, 1837.) When the constriction took place at a later period after death, there was no particular effect produced.

We learn from these experiments, as well as from those performed by other observers, that the mark which is usually seen on the neck in hanging during life, (non-ecchymosed,) may be also produced by a ligature applied to the neck of a subject within two hours after death,—consequently the presence of this mark on the neck is no criterion whether the hanging took place during life or after death. The changes in the skin beneath the mark are also destitute of any distinctive characters; there is the same condensation of the cellular membrane whether the hanging have occurred in the living or dead. These changes are the simple result of a physical cause,—mechanical compression.

Summary of medical evidence.—From the foregoing considerations, we draw the conclusion that there is no distinctive sign by which the hanging of a living person can be determined from an inspection of the dead body. All the external marks may be simulated in the dead subject, and the internal appearances furnish no evidence whatever. Still, when the greater number of the signs enumerated are present, and there is no other satisfactory cause to account for death, we have strong reason to presume that the deceased has died from hanging. We must not, however, abandon medical evidence on these occasions, merely because plausible objections may be taken to isolated portions of it. Facts may show that, however valid such objections may be in the abstract, they are wholly inapplicable to the particular case under investigation. Perhaps the greatest medical difficulties occur in reference to cases of suicide, owing to the slight appearances which here attend
this form of death; but on these occasions, moral and circum-
stantial proofs are so generally forthcoming, that even an inspec-
tion of the body is scarcely ever deemed necessary by a coroner! If, then, it be admitted by a medical jurist, that it is not in all cases possible to distinguish hanging in the living from hanging in the dead body, the admission must be considered as having reference to cases wherein individuals destroy themselves, and not to cases in which they are destroyed by others. Even if a doubt were raised in any particular instance, it is more than probable that circumstantial evidence would furnish data for a decision, and thus satisfactorily make up for the want of ordinary medico-legal proofs. If we found a deeply ecchymosed mark around the neck of a dead subject, we said, all other circumstances being equal, that the individual had most probably died by hanging, we should not be departing from a proper discharge of our duty; since although it is medically possible that such a mark may be produced after death, yet as it would be only a murderer who would think of hanging up a recently dead body to simulate suicide, so it is certain, that in such a case we should most probably find some very obvious indications of another kind of violent death about the person. The absence of these, and the presence of ecchymosis in the course of the cord, would, it appears to me, leave the question of vital hanging decidedly settled in the affirmative. It is necessary that great caution should be used in expressing an opinion that the hanging probably took place after death, merely from the absence of ecchymosis in the seat of the ligature; because, while this is generally true, it may in particular cases lead to the concealment of the real mode of death. Many facts already adduced show that numerous cases of hanging during life would be pronounced to be cases of hanging after death, if this were taken as a criterion. The mere discovery of violence about the person is not of itself sufficient to rebut the presumption of death from hanging on these occasions. The violence should at least be of such a nature as to account for the immediate destruction of life, or it can throw no light upon the question whether the individual might not have died from hanging, in spite of the marks of maltreatment found upon the body.

If, in the case of a person found hanging, a medical jurist should assert that death had not taken place from this cause, this would be tantamount to declaring that the deceased must have been murdered:—because it is impossible to admit that any but a murderer would hang up a recently dead person. This hanging after death has been frequently carried out with the view of concealing the real mode of death, and of making the act appear to be one of suicide. The following case is reported by Devroux. A female was found suspended to a beam in a barn. Owing to the absence of all the usual marks of hanging about the face
and neck of the deceased, a careful examination of the body was made. In the course of the inspection, a small penetrating wound evidently inflicted by a round instrument, was discovered on the right side of the chest, but in great part concealed by the breast of that side. On tracing the wound, it was found to pass between the fifth and sixth ribs, completely perforating the heart from the right to the left side. A considerable extravasation of blood had taken place internally, which had been the cause of death. It was therefore evident from the result of this examination, that the deceased had been killed, and her body suspended after death. (For a precisely similar case by Prof. Vrolik, see Casper, Woch. Feb. 1838.) Fodere refers to a case in which an individual was found hanging under somewhat similar circumstances, and on examination it was discovered that death had been caused by the administration of poison,—the body having been subsequently suspended. In one instance Denvergie discovered a quantity of plaster of Paris in the stomach and intestines of a person found hanging. There are, however, cases in which some embarrassment may occasionally arise. It may be a question whether the discovery of poison in the body of a person found hanging is consistent with a previous attempt at suicide by poison. An individual has even been known to hang himself after or about the time that he had swallowed a strong dose of prussic acid.

Marks of violence on the hanged.—The presence of marks of violence on the body of a hanged person is important; and it will be proper for a witness to notice accurately their situation, extent, and direction. Having satisfied himself that they must have been received during life, he will have to consider the probability of their being of accidental origin or not. These marks of violence are not always to be regarded as furnishing unequivocal proofs of murder; for it is possible that they may have been inflicted by the individual himself before hanging, and not succeeding in committing suicide by these attempts, he may subsequently have resolved to accomplish his purpose by suspending himself. Let the witness duly reflect on these circumstances before he allows his opinion to implicate any party,—let him consider that a hanged subject may bear the marks of a gun-shot wound, his throat may be cut, his person lacerated or disfigured, and yet, before a suspicion of homicide is allowed to be entertained, it ought to be clearly shown that such injuries could not, by any probability, have been self-inflicted. The importance of observing caution in such a case will be still more manifest, when there is no ecchymosis produced by the cord, and the face does not present the usual characters of hanging. Marks of violence on a hanged subject may in some cases be fairly ascribed to accident. If the individual have precipitated himself with any violence from a chair or table in a furnished apartment, he may have fallen
against articles of furniture, and thus may have given rise to lacerations and contusions, especially on the extremities. Again, it is possible to imagine that the rope may have given way, and the individual, in falling, have injured his person; but he may afterwards have had resolution enough to suspend himself again. Such an occurrence may be rare; but when the perusal of these injuries is made to form the chief ground of accusation against a party as the murderer, their accidental origin ought not to be lost sight of by a considerate witness. If we suppose the person to have been hanged in a state of intoxication or stupefaction, medical evidence alone will rarely suffice to determine the question of homicide or suicide. The absence of all marks of violence from the body might actually lull suspicion. It is proper on these occasions to look to the hands of the deceased, since it is with these that a person defends himself; and unless taken unawares, it is almost certain, if the hanging were homicidal, that there would be traces of violence on these parts. The clothes would be torn and discomposed, and the whole appearance of the deceased would be that of one who had done his utmost to resist a violent murderous attack. There are some injuries which could not be attributed to accident under the circumstances. Among these we may enumerate fractures, dislocations, deeply penetrating incised and gun-shot wounds. Now the question is, Do these serious injuries necessarily establish homicide? The answer must be in the negative: although when fractures or dislocations exist, there are very strong grounds for suspicion.

Suicides, it must be remembered, are capable of making many attempts on their lives by various means. In the spring of 1836, a gentleman was found dead, hanging in his bed-room at an inn. His dress was much disordered; and blood, which had issued from a deep wound in the throat, was found scattered over the floor. From the facts proved, there was no doubt that this had been an act of suicide: and that the deceased, previously to hanging himself, had first attempted to cut his throat. Had his body been found in an exposed situation, this wound in the throat might have given rise to a suspicion of murder. The following somewhat remarkable case occurred at Walworth in 1836. A young man was found hanging in his bed-room, quite dead. He was suspended by his cravat, and his feet were within an inch of the floor. The door of the room was fastened on the inside, and it was proved that no one could have had access to it. An earthen pan was found near the bed, containing about a pint of blood, which appeared to have issued from a very deep incision in the bend of the left arm of the deceased. The razor with which this had been inflicted was found on the mantelpiece. It came out in evidence, that on the night previously, the deceased had swallowed a quantity of arsenic, and had suffered severely from the effects of the poison; although at the time it was sup-
posed that his illness was due to other causes. In this case there were three modes by which suicide was attempted. The deceased had first taken poison, then wounded, and afterwards hanged himself. There could be no doubt that death was caused by hanging; and had the wound been inflicted, and the poison administered by other parties, this opinion might have been safely expressed. Had the body been found hanging in a suspicious locality, these circumstances would have created a strong presumption of murder.

The following case is reported by M. Dégranges:—A man was found hanging in a room by a cord attached to a nail in the ceiling. In the upper and fore part of his neck there was a deep wound, through which the cord had passed. A ladder was placed against the wall by the side of the body. About a pound of coagulated blood was found on the floor, as well as in different parts of the apartment; and some linen, covered with blood, was discovered near the body. In the table-drawer, in the apartment above, was found some cord sprinkled with blood, as if a bloody hand had been searching in it. On the staircase between the two apartments there was no trace of blood. The deceased’s apartment was secured on the inside by the door being bolted. An opinion was demanded of the reporter respecting the manner in which the deceased had died, and the probability of his having been murdered. The deceased’s clothes were spotted with blood, and his hands were also bloody. The body externally did not present the slightest trace of any ecchymosis or other mark of violence. The hands were likewise free from violence; the fingers contracted, and the nails blue. There were patches of cadaveric lividity scattered over the trunk; and it was evident that the face had been discharged. The face had a slight violet tint, and the tongue projected about an inch from the mouth. This organ had been forcibly compressed by the teeth. The wound in the throat was situated between the chin and os hyoideus (bone of the tongue) and extended from the angle of the jaw on one side to the opposite angle. It had penetrated through the cavity of the mouth to the pharynx, but had only divided some small branches of the thyroidea artery: it had evidently been inflicted after several attempts, for its edges were irregularly cut. The cord, in passing through the wound, had lacerated, and extended it at the two extremities. The cerebral vessels were filled with blood; the cervical vertebrae were uninjured, and the stomach was free from any trace of poison. The opinion given from these data was to the effect, that the deceased had died from hanging, and that he had hanged himself.

When we consider that in this case the deceased had laid open his throat as far as the vertebral column, dividing the right superior thyroidea artery, by which so much blood had been lost that it was not unlikely he would have soon fallen into a state of syncope, it is remarkable that he should have had sufficient pre-
sence of mind and muscular power to have done what the evidence shows he must have done, namely, to have placed a handkerchief on his wound in order to arrest the haemorrhage; to have gone upstairs to another room, and have searched in a table drawer for the cord with which he intended to hang himself; to have placed a ladder against a wall, and to have made use of this for the purpose of fixing a cord to a nail in the ceiling, an act which could only have been performed with great difficulty. When we duly reflect on all these circumstances, it does not appear extraordinary that the magistrate who ordered the examination should have been prepared to receive an account of the deceased having been murdered. Much, it is true, rested upon the moral and circumstantial proofs; as for example, on the previous state of mind of the deceased, and the fact of his room having been found secured on the inside. Casper mentions a case in which a woman was found hanging in her room. On examining the body, two penetrating wounds were seen on the left side of the chest. These had perforated the pericardium, and touched the surface of the heart, without entering its cavities. There was a basin of bloody water and a bloody sponge on the table; the right hand of deceased was stained with dried blood, and the door and window were fastened on the inside. There was no doubt that this was a case of suicide, and that, after inflicting the wounds, the deceased had suspended herself. The mark on the neck was nowhere ecchymosed, but of a yellowish or parchment colour. There was nothing in the nature of the wound to have prevented self-suspension. (Ger. Leich. Oeffn. ii. 89.)

The remarks made relative to incised wounds will apply to gun-shot wounds. A suicide may attempt to destroy himself with a pistol: he may fail in the attempt, and ultimately hang himself. Any description of gun-shot wound, provided it be such as to allow of a person surviving a sufficient time, may thus be found on a hanged subject, and yet constitute no proof whatever of homicide. If there be circumstances about the wound or injury which prove that it could not have been self-inflicted, this of course will affect the conclusion; but when such circumstances are not met with, a cautious medical jurist should say, in answer to inquiries respecting the origin of these wounds, that they may have been inflicted either by the individual himself or by another. There might be no medical facts which would directly establish either view. Of course if, in any case, the wounds or injuries be of a decidedly mortal nature, and have probably caused death, the presumption of murder amounts almost to positive certainty; for who but a murderer would suspend the dead body of a person so wounded, immediately after death? (Ann. d'Hyg. 1835, ii. p. 410.) In one instance of suicidal hanging, there were lacerated wounds upon the head, and a handkerchief was found blocking up the mouth. (Henke's
CASES OF ACCIDENTAL HANGING.

Was the hanging the result of accident, homicide, or suicide? — Most medical jurists have passed over the subject of accidental hanging, probably believing it to be impossible. In the sense commonly implied by the term, it is certainly unusual, but although rare it is a possible occurrence. Dr. Smith mentions a case which occurred some years since, in which a girl of the age of thirteen was hanged by pure accident. She was swinging in a brewhouse, and near the rope used by her for that purpose was another for drawing up slaughtered sheep. In the course of the exercise, her head got through a noose of this second cord, which pulled her out of the swing, and kept her suspended at a considerable height until dead. The following case was communicated to me by one of my pupils. In December 1833, an inquest was held on the body of a boy aged ten years. It appeared in evidence that he had been playing with a child eight years old, who was the only witness of his death. The deceased had been amusing himself in swinging by fastening a piece of plaid-gown to a loop in a cord which was suspended from a beam in the room. In the act of swinging, he raised himself up, and gave himself a turn, when the loop of rope suddenly caught him under the chin, and suspended him until life was entirely extinct. The boy who was in the room with him did not give any alarm for some time, thinking that the deceased was at play. The jury returned a verdict of "accidentally hanged." Another case occurred in London in 1836. A man who was in the habit of exercis ing himself in gymnastics on the rope, was one morning found dead and suspended in his bed-room. The rope had passed twice round the body and once round the neck, whereby it had caused death, although the legs of the deceased were resting on the floor. There was no doubt that the deceased had been accidentally hanged. These are two among several instances which have come to my knowledge, and it will be seen that the circumstances under which they occurred were sufficiently decisive of the manner in which the hanging took place. Indeed, circumstantial evidence must always suffice for the discrimination of accidental hanging; and we have therefore merely to inquire whether, when an individual is found hanging under circumstances which do not allow of the suspicion of accident, the act be the result of suicide or of homicide. A medical witness must remember that this is strictly a question for the jury. It is not for him to say whether a man has hanged himself or been hanged by others, but merely to state, when required, those medical circumstances which support or rebut one or the other presumption.

Homicidal hanging.—It has been very rarely observed, that of all the forms of committing murder, of the most difficult, and it is, therefore, but seldom most cases
when an individual has been hanged by others, it has been after death, in order to avert the suspicion of homicide. Hence the discovery of a person hanging, affords primâ facie evidence of suicide, supposing it to be rendered absolutely certain that death has taken place in this manner. We must, however, admit that an individual may be murdered by hanging, and the appearances about his body will not afford the smallest evidence of the fact. The circumstances which will justify a medical jurist in making this admission are the following. First, when the person hanged is feeble, and the murderer a strong healthy man. In such a case, a child, a youth, a female, or an individual at any period of life, worn out and exhausted by disease or infirmity, may be in this way murdered. Secondly, when the person hanged, although usually strong and vigorous, is at the time in a state of intoxication, stupefied by narcotics, or exhausted by his attempts to defend himself. Thirdly, in all cases murder may be committed by hanging when many are combined against one individual. With these exceptions, then, a practitioner will be correct in deciding in a suspected case, in favour of the presumption of suicide. Unless the person labour under stupefaction, intoxication, or great bodily weakness, we must expect, in homicidal hanging, that there will be evident marks of violence about the body; for there are few who would allow themselves to be murdered without offering resistance,—notwithstanding the assertion of Mahon, that some might submit to this mode of death with philosophical resignation when they saw that resistance was hopeless! The following singular case of attempted murder by hanging is mentioned in Symes's Justiciary Reports, Edinburgh, 1827. A woman, aged sixty-nine, was charged with attempting to hang her husband, who was some years older. It appeared that the prisoner contrived to twist a small rope three times round the neck of her husband, while he was lying asleep. She then tied him up to a beam in the room in such a manner that when the neighbours entered he was found lying at length on the floor, with his head raised about one foot above it. He was quite insensible; his hands were lying powerless by his side, his face was livid, and it was some time before he could be roused. Had he remained three minutes longer in this position, he would have died. According to his statement, he went to bed quite sober, and he was not aware of anything which passed during the attempt to hang him, or afterwards, until he was resuscitated. The prisoner was convicted of the assault without previous malice, she having had no ill-will against her husband, and being at the time intoxicated. It can hardly be considered possible that any man should be so sound asleep as not to be awakened by the attempt thus made to hang him. The probability is, that the prosecutor was, like his wife, intoxicated. A case of alleged murder by hanging, and of considerable difficulty in its medical investigations, was tried at the Exeter Summer Assizes, 1851 (Reg. v.
ROUSE). Although the prisoner was acquitted, there were some strong facts leading to the belief that this could not have been an act of suicide.

Some medical jurists have thought that the mark left by the cord on the neck would serve as a criterion on which we might depend. Thus it has been said, if the mark be circular, and placed at the lower part of the neck, it is an unequivocal proof of murder. In hanging, the mark of the cord is generally oblique, being higher at the back part of the neck, in consequence of the loop formed by it yielding more in this direction than in front. But it is an error to suppose that this want of obliquity in the impression can afford any evidence in favour of the act having been homicidal. Its form will depend in a great degree upon the fact of the body being supported or not, for it is the weight of the body which causes its obliquity; it will also depend on the manner in which the cord is adjusted. A case of suicidal hanging is related by Ortifa, in which the mark of the cord extended horizontally round the neck from behind forwards. (Méd. Lég. tome ii. p. 376.) The slip-knot of the cord was in front of the neck, and it is obvious that when the cord is thus adjusted by a suicide, there will be scarcely any obliquity in the depression produced by it. Equally ill-founded is the assertion, that the existence of two impressions on the neck affords positive proof of homicidal. One of these impressions may be at the lower part of the neck, and circular; the other at the upper part, and oblique: it is therefore contended that the deceased must have been strangled in the first instance, and afterwards hanged. The possibility of a prior attempt being made by a suicide to strangle himself, is not adverted to: "si l'on observe les deux impressions," says Mahon, "l'assassinat est alors parfaitement prouvé." It is fortunate that there are facts on record to oppose to this very decided statement. One of the first cases reported by Esquirol is that of a female lunatic, who committed suicide by hanging herself, and on whose neck two distinct impressions were seen — the one circular, the other oblique! These appear to have arisen from the cord having been passed twice round the neck, the body being at the same time partially supported. In some instances, a presumption of homicidal interference may exist if there be two distinct impressions, but it cannot be admitted that they establish the fact of murder.

The injury done to the neck by the cord can rarely afford any clue to the manner in which hanging took place, unless the circumstances under which the body is found, favour the presumption of homicide or suicide. Thus the laceration of the muscles and vessels of the neck, the rupture of the trachea and the displacement of the larynx, stretching of the vertebral ligaments, and effusion on the spinal sheath, may be observed in suicidal as in homicidal hanging. The presumption, however, is obviously
in favour of the latter when these violent injuries are found to be accompanied by fracture or displacement of the cervical vertebra, and the body of the deceased is not corpulent,—the ligature by which he is suspended is not of a nature to produce them, and the fall of the body has not been great.

Injury to the cervical vertebra.—A much disputed question has arisen in medical jurisprudence, whether the cervical vertebra can become fractured or displaced in suicidal hanging. Most medical jurists deny the possibility of this accident occurring,—the displacement or fracture of these vertebra being rarely observed, even in criminal executions, where the greatest violence has been often used by the executioner. So far as I am aware, there is no case of suicide on record in which this injury to the neck existed. The case referred to by Petit, which was left to the decision of Dr. Pfeffer, is unsatisfactory, because the body was not examined; and it is doubtful whether the act was really one of suicide or not. M. Ansiaux, of Liège, in inspecting the body of a woman who had hanged herself, found extravasated blood behind the two first cervical vertebrae, which were more widely separated posteriorly than usual. On removing the vertebrae, the posterior ligament of the spine was found ruptured, and the transverse ligament of the atlas so stretched that the dentiform process of the second vertebra was completely locked against the articular surface. The perpendicular and oblique ligaments were entire. The deceased was a stout healthy person; when discovered, her body was suspended from a beam at the distance of about a foot and a half from the floor. She had evidently fallen with considerable force. The case of this female will serve to show that severe injury to these deep-seated regions of the neck may be occasionally met with in suicidal hanging. A case somewhat similar to this has been reported by Mr. Campbell de Morgan. (Lancet, August 10, 1844.) A married woman, aged fifty, worn out and exhausted by disease, was found hanging quite lifeless from the rail of a bed, which was not more than five feet eight inches from the ground. The front of her body was turned round towards the bed, the head thrown forcibly backwards,—the knot of the ligature, an old silk handkerchief, being placed in the middle of the under side of the chin. Her heels were about three inches from the ground,—the knees being on a level with the bed-frame, and resting against it. The body was seen by a medical man about an hour after it was cut down,—the features were perfectly calm, and there was no trace of congestion about the face: it was pale, and in all respects natural. There was no lividity; the eyes were neither injected nor prominent; the tongue pale, lying far back in the mouth, and without any mark of indentation. The cord-mark well defined and, like parchment, dry, brown, and hard, without any ecchymosis, but with a thin line of congestion at the upper edge of the groove;
HANGING. CIRCUMSTANTIAL EVIDENCE.

— it was very deep at the back of the neck, just over the atlas, probably owing to the head hanging backwards. The mucous membrane of the stomach was pale; the lungs natural; no congestion of the large veins or of the cavities of the heart; the two ventricles contained about an equal quantity of blood. These appearances seemed to show that death was not caused either by asphyxia or by cerebral congestion. Neither the trachea nor the great vessels of the neck could have sustained any pressure or constriction. The deep muscles over the second and third cervical vertebrae were ecchymosed; this ecchymosis extended to the sheath of the spinal marrow; and on the left side, and externally to the sheath, there was a large effusion of blood firmly coagulated. There was no displacement of the second or other vertebrae, and the ligaments were sound; but between the third and fourth vertebrae, there was unusual mobility as if they had been stretched. In this case the body was not heavy, and the fall, if any, could have been but trifling. The effusion on the spinal marrow was the cause of death; and its origin was sufficiently explained by the falling back of the head and sudden bending of the cervical vertebrae. Her husband and family were in an adjoining room, but heard no noise: it was only by accident that the deceased was discovered.

Circumstantial evidence. — In all doubtful instances, we should not lose sight of moral and circumstantial evidence. We should ascertain whether the individual had been previously disposed to commit suicide or not; — we should observe whether the doors and windows of the apartments are secured on the inside or on the outside; — whether the dress of the deceased is at all torn or discomposed, or his hair dishevelled; — whether the attitude of the body is such as to show interference after death; — whether there are marks of blood about the body, or the ligature; — whether the hands are bloody or present marks of wounding or struggling; — whether the rope or ligature corresponds to the impression seen around the neck; — and lastly, whether the ligature be of sufficient strength to support the weight of the deceased. (Case of Pinckard, post, p. 812.) The strongest evidence of homicide is often found in the attitude and the state of the dress of the dead body. It may or may not indicate interference or change after death irreconcilable with the supposition of suicide or accident. On this point the minutest circumstance may become of considerable importance as evidence. When there are indications of violent struggling, the dress may be found disordered, unless it has been smoothed or arranged by the murderer after the death of the deceased (post, p. 812). There may of course be no disorder or discomposure of the dress, in the case of a female, when the body is fairly suspended. These points fail, it is true, more within the province of the officers of justice than of a medical practitioner; but the latter is generally the first who is called.
to see the deceased, and therefore, unless such facts were noticed by him on his visit, they might often remain altogether unknown. The medical opinion, however, must be based on medical facts. Circumstantial evidence has more than once assisted in clearing up a doubtful case. Louis states that on removing the body of a man who was found hanging, the rope was observed to be clotted with blood. This simple circumstance led to further investigation, by which it was discovered that the person had been murdered, and his body afterwards suspended. The presence of marks on the neck indicative of strangulation, such as the cord was not likely to have produced, may lead to a suspicion that the hanging followed death. In April 1829, a boy was found hanging perfectly dead. On inspecting the body, a round ecchymosed mark, about the size of a dollar, was seen on the fore part of the neck; and near it were several impressions as of fingers in the surrounding skin. There was neither depression nor ecchymosis in the course of the cord. The inspection left no doubt that the deceased had died from asphyxiation. It was subsequently discovered that the boy had been first strangled, and afterwards hanged. In another case a man was found hanging in a room. His body was so suspended from a hook, that the trunk was not more than nine inches from the floor; and his legs were stretched out at length. The cord was from two to three feet long, and was loosely passed round the neck. The furniture of the room was in great disorder, and some marks of dried blood were seen on one part of the floor. The right side of the head and face of the deceased presented several excoriated and ecchymosed marks. There was a circular impression around the neck produced by the cord; but it was entirely free from ecchymosis. On the left side, a little above this impression, there was a strongly ecchymosed mark, which could be traced round to the back of the head. Blood was found extravasated beneath this mark. The lungs presented the characters of asphyxiation, but the examiners referred this to strangulation and not to hanging, considering that the body had been suspended after death in order to give the appearance of suicide. Had there been an ecchymosed mark on the neck, which could not have resulted from the suspending cord, the case would have remained, medically speaking, doubtful; because it is well known that the affirmative signs of hanging may be absent, and yet the individual may thus have died. (See the case of Pinckard.

Strangulation, post, p. 812.)

The position of the body. — Lastly, it has been contended that the position of the body may serve to distinguish suicidal from homicidal hanging. This point was strenuously argued on the investigation which took place relative to the death of the Prince de Condé in 1830. According to the opinions of some of the witnesses on that investigation, if the body of a man be found in
an inclined posture, or so suspended that his feet are in contact with the floor, the idea of suicide by hanging is at once negatived, — we are rather to suppose that the person must have been otherwise destroyed, and his body afterwards placed in that position by his murderers. Here, then, we are called upon to admit that suicidal hanging is improbable, if not impossible, unless the body of the deceased be found freely and absolutely suspended without any support! This very strong opinion, it will be seen, is not borne out by facts. In order that death should take place by hanging, it is not necessary that the body should be freely and perfectly suspended. Cases are of very frequent occurrence, where the bodies of hanged persons are found with the feet on the ground, kneeling, sitting, or even in the recumbent posture. These are truly mixed cases of hanging and strangulation. I have now before me the reports of eleven cases of suicidal hanging or strangulation which have occurred within the last few years. In three the deceased were found nearly recumbent; in four in a kneeling posture,—the body being more or less supported by the legs; and in four, the persons were found sitting. (For many singular cases of this kind, with plates, see Annales d'Hyg. 1830, i. 166; 1831, p. 157; 1834, i. 472.) In one instance, the deceased was found on his knees at the foot of the bed, with his cravat round his neck,—the other end being thrown over the bed-rail, and then twisted tightly round his right hand. In another, the deceased, a prisoner, was found dead in the sitting posture. (Ann. d'Hyg. 1831, i. 196.) He was hanging to the iron bar of the window of his prison, which was so low that he was almost in a sitting posture. The ligature which he had employed was a cravat, but (what was more remarkable in the case) the hands of the deceased were found tied by another handkerchief. The body was warm when discovered. There was not the least doubt of this having been an act of suicide; yet, as the reporter observes, had the body been found in an unfrequented spot, the discovery of the hands tied, if not the position, would have led to a strong suspicion of murder. In the opinion of the reporter, the deceased had contrived to tie his hands together by means of his teeth. (Ann. d'Hyg. 1832, i. 419.) Among the cases collected by Esquirol, is the following. A patient in La Charité was found one morning hanging by a rope which was attached to the head of his bed. He had fastened this by a loop round his neck, but his body was so retained, that when discovered he was on his knees by the side of his bed. There are one or two similar instances related by the same author. Mr. Webb met with a case in which a man destroyed himself while lying at full length on a bed. His hand was in a loop formed by a leather strap fastened to the bed-post. (Med. Times and Gaz. Aug. 7, 1852, p. 137.) The following case fell within my own knowledge. In 1832, a man was found hanging in his room, with his knees bent
HANGING. EVIDENCE OF SUICIDE.

forwards, and his feet resting upon the floor. He had evidently been dead for some time, since cadaveric rigidity had already commenced. The manner in which this person had committed suicide was as follows: — He had made a slip-knot with one end of his apron (he was a working mechanic), and having placed his neck in this, he threw the other end of the apron over the top of the door, and shutting the door behind him, he had succeeded in wedging it in firmly. At the same moment he had probably raised himself on tip-toe, and then allowed himself to fall; in this way he died. The weight of his body had already sufficed to drag down a part of the apron, for it seemed as if it had been very much stretched. (See also a case by Dr. Albert, Henke, Zeitschrift, 1843, ii. 50.) Casper reports a case in which a man was charged with the murder of his wife because her body was found hanging in almost an erect position. (Ger. Leich. Offfn. ii. 92.) Mr. Rake (a former pupil) has communicated to me the particulars of a well-marked case of suicidal hanging which occurred in August 1852, in which the person was found in almost a sitting posture. A man, at 21, hung himself by a silk handkerchief passed through a ring only twenty-six inches from the ground. Mr. Rake saw him in a few minutes after he had been cut down. The body was quite warm. When first seen the man was lying with his feet extended at full length, the handkerchief was drawn tightly round the throat by a slip-knot, and his face was directed towards the ground. Both hands were firmly clenched. There was a well-defined, nearly circular, and much indented mark round the lower part of the neck corresponding to the ligature. The ligature was drawn so tightly at one or two points, as to appear almost buried in the folds of the skin about the neck. There was a good deal of ecchymosis at various spots in the back of the ligature, and some abrasion of the cuticle at two or three points. There was swelling with great congestion of the face. There was no escape of blood from the ears.

Mr. Becke, coroner for Northampton, has furnished me with three additional cases, which occurred at the General Asylum for Lunatics, in 1852. In the first, the man made a loop of a twisted blanket at a height of less than five feet from the ground, and then kneeling forward strangled himself, the feet being on the ground and the knees nearly touching it. The fingers were not clenched or contracted, but partially bent. There were no marks of any convulsive struggle except a slight bruise on the wall. In the second case the man hung himself on a beam: the legs touched the ground: the hands were not clenched. In the third, the patient had hanged himself by mounting on a shelf in a loft, fastening his neck-handkerchief to a beam, and then swinging himself off. He was found with his right leg suspended in the air, whilst his left leg was supported by the shelf on which
he had been standing. His right hand was convulsively clenched, which is said to have been a habit on the part of the deceased; the left hand was open, and the fingers only slightly bent.

Remer found that out of one hundred and one cases of suicidal hanging, in fourteen the body was either standing or kneeling, and in one instance it was in a sitting posture. Dr. Duchesne has recently published an account of fifty-eight cases in which the suspension of the body was partial,—the feet or trunk being more or less supported. Twenty-six of these cases are new. The reporter comes to the conclusion that suicide by hanging is consistent with any posture of the body, even when resting upon the two feet. (Ann. d'Hyg. Oct. 1845, ii. 141 and 346.) Further evidence need not be adduced to show how unfounded is that opinion which would attach the idea of homicidal interference to cases in which a body is loosely suspended, or in which the feet are in contact with any support. We ought rather to consider these facts as removing a suspicion of homicide; for there are probably few murderers who would suspend their victims, either living or dead, without taking care that the suspension was complete. Besides, the facts of many of these cases are readily explicable:—thus, if the ligature be formed of yielding materials, or if it be loosely attached, it will yield to the weight of the body after death, and allow the feet to touch the floor, which they might not have done in the first instance. If there be reason to believe that the body has not altered its position after suspension, we must remember the facility with which insensibility comes on, and the rapidity with which death commonly ensues in this form of asphyxia. (See Med. Gaz. Vol. xliv. p. 85.)

The limbs secured in suicidal hanging.—One or two other points are also worthy of notice in relation to this question. The hands or the legs, but more commonly the former, have been frequently found tied in cases of undoubted suicidal hanging (Ann. d'Hyg. 1832, i. 419): and yet it has been gravely debated, whether it was possible for a person to tie or bind up his hands, and afterwards hang himself! It is unnecessary to examine the ingenious arguments which have been urged against the possibility of an act of this kind being performed; since among many cases that might be quoted, two occurred in 1843, in this metropolis, where the persons died from hanging: the act was suicidal, and the hands were found tied in both instances with a silk handkerchief. A third case occurred at Worcester, in December, 1844, in which the deceased tied his wrists with a silk handkerchief; and secured to this, were two flat irons in order to increase the weight. A remarkable case of suicide in which the hands and ankles were tightly secured has been communicated to the Medical Gazette, by Mr. J. H. Taylor, Vol. xlv. p. 388; see also cases in Guy's Hospital Reports, Oct. 1851.

Power of self-suspension.—It has been a deba
whether corporeal infirmity, or some peculiarity affecting the hands, might not interfere with the power of an individual to suspend himself. This question can be decided only by reference to the special circumstances of the case. In the case of the Prince de Condé, it was alleged that he could not have hanged himself in consequence of a defect in the power of one hand:—it was said that he could not have made the knots in which the cravats by which he was suspended were tied. Allegations of this kind appear to have been too hastily made in this and other instances. A determined purpose will often make up for a great degree of corporeal infirmity; and unless we make full allowance for this in suicide, we shall always be exposed to error in drawing our conclusions. Connected with this, is the question how far weakness or infirmity from age may interfere with this form of suicide. Suicide by hanging under any circumstances, among young subjects, is rare. Out of one hundred and ninety-eight suicides, observed by M. Esquirol, at the Salpêtrière, there were but two instances of subjects under fifteen years of age. (Ann. d’Hyg. 1836, ii 400.) The youngest age at which I have met with a case of suicidal hanging was in a boy of nine years, who hanged himself at Hampstead, in April, 1837. The greatest age was in the case of a man of ninety-seven, who committed suicide by hanging in September, 1842. In a former part of this chapter, it has been stated that asphyxia in hanging may be very insidiously induced, so that although the individual may appear to have had the power of easily rescuing himself, yet the exercise of this power is impossible. The transition from life to death in such a case is as rapid as it is imperceptible. This will explain why persons so readily die from slight constriction of the trachea, when their bodies are partly supported, either standing, kneeling, or sitting:—why, also, it is not necessary that the cord or ligature should be drawn tightly round the neck; and lastly, why, as it has frequently happened, this form of suicide should be easily perpetrated by persons labouring under disease or infirmity in a room where others are present or near, but who are not aware of the act. The last circumstance has in more than one instance given rise to an ill-founded suspicion of murder. When an individual has obviously died by hanging, and the presumption of suicide is rebutted, or the act itself denied by a medical witness, the only alternative is, that it must amount to murder. It is not possible to conceive that the act of hanging another can ever admit of justification or excuse. When, in the case of death from drowning or wounds, it is doubtful whether the act should be referred to suicide or homicide, the admission of its having been homicidal does not necessarily cut off all hope from the accused. The deceased may have been drowned or wounded accidentally, or he may have been drowned or wounded intentionally; but under circumstances of great provocation. The act, therefore, may
SUICIDAL HANGING.

799

turn out to be a form of manslaughter. In hanging, however, the defence could never be that the act was accidental, nor is it possible to believe that the law would admit provocation as a justification for what must have been so deliberately done. The act itself, like poisoning, would be at once evidence of malice. With this knowledge, then, of what the absolute denial of suicide must lead to in a suspected case, a witness is bound to examine closely every medical presumption which can be construed in the least degree unfavourably to an accused party. One of the most remarkable cases on record is that of the Prince de Condé, which occurred in 1830, and excited the attention of the medical jurists of France and England. It involves many of the questions connected with the medical jurisprudence of hanging. (For a full account of this singular case, which in my opinion was one of suicide, I must refer the reader to the Ann. d’Hyg. 1831, p. 157.)

Is blindness a bar to suicidal hanging?—The answer to this question is decidedly in the negative, not from theory, but from actual facts; although some might be inclined to doubt whether a man labouring under such an infirmity could really thus destroy himself. In February, 1837, an inquest was held in London, on the body of a blind man, who was found dead hanging in an outhouse. The evidence left not the smallest doubt of his having committed suicide.
CHAPTER LX.

CAUSE OF DEATH — APPEARANCES AFTER DEATH — WAS DEATH CAUSED BY STRANGULATION, OR WAS THE CONSTRICION APPLIED TO THE NECK AFTER DEATH? — CASPER'S EXPERIMENTS ON STRANGULATION AFTER DEATH — MARKS OF VIOLENCE — ACCIDENTAL, HOMICIDAL, AND SUICIDAL STRANGULATION — CASES.

Strangulation. Cause of death.—Hanging and strangulation are usually treated together; and some medical jurists have admitted no distinction in the meaning of these terms. In hanging, the phenomena of asphyxia take place in consequence of the suspension of the body, while in strangulation, asphyxia may be induced not only by the constriction produced by a ligature round the neck, independently of suspension, but by the simple application of pressure through the fingers or otherwise to the trachea. It may, indeed, be said, that every individual who is hanged is literally strangled; but hanging is only one form of strangulation, and sufficiently peculiar to claim a separate consideration. We have now, therefore, to direct our attention to the other means which have been employed to obstruct the respiratory process by external pressure on the trachea. These have commonly been arranged and treated under the head of manual strangulation. The cause of death is the same in the two cases, namely asphyxia; and the rapidity with which death ensues in strangulation will depend in a great degree on the force employed, and on the completeness with which the respiratory process is obstructed. In strangling, a much greater degree of violence is commonly employed than is necessary to cause asphyxia; and hence, the marks produced on the skin of the neck, will be, generally speaking, much more evident than in hanging, where the mere weight of the body is the medium by which the trachea is compressed. The treatment is the same as that recommended in cases of hanging. (See ante, p. 772.)

Appearances after death.—The appearances after death externally and internally are the same in strangulation as in hanging, but the injury done to the parts about the neck is commonly greater in the former case than in the latter. If much force has
been used in producing the constriction, the trachea with the muscles and vessels in the fore part of the neck, may be found cut or lacerated, and the cervical vertebrae may be fractured. The face is more commonly livid and swollen, the eyes congested, and the pupils are dilated. The mark of the ligature, if a ligature has been used, is generally circular, and situated at the lower part of the neck. Instances have, however, been related where a circular mark has been observed in hanging; and it is possible that some degree of obliquity may occasionally exist in the course of the depression produced by a ligature in strangulation. A medical jurist ought, therefore, to weigh all the circumstances connected with the position of the body, and the direction of the ligature, before he forms an opinion whether the individual has been hanged or strangled. Much more importance is to be attached to the lividity, ecchymosis, and abrasion of the skin in the course of the ligature, than to the circularity or obliquity of the depression produced by it. In the strangling of a living person by a cord, it is scarcely possible that a murderer could avoid producing on the neck marks of violent injury; and in the existence of these we have evidence of the manner in which death has taken place, which we cannot always expect to find in hanging. On the other hand, a person may be strangled, and yet the ligature in consequence of its being soft and of a yielding nature, will not cause a perceptible depression or ecchymosis. Such instances must, of course, be rare: because murderers usually produce a much more violent constriction of the neck than is necessary to ensure the death of a person. The general lividity of the body, contraction of the fingers, with clenching of the hands, and swelling and protrusion of the tongue, are the same in strangulation as in hanging. Mucous froth may also be occasionally found in both cases. The internal appearances are those of asphyxia. The lungs and right cavities of the heart are commonly distended with thick black blood, while the left cavities are empty. (See ante, page 737.) The state of the brain and its membranes calls for no particular notice. The blood-vessels are sometimes found distended. In some instances of strangulation, it is said that blood has escaped from one or both ears during the act; but this is not a usual appearance. In two well-marked cases to be related hereafter (p. 812.) the constriction was carried to a great degree, but there was no bleeding from the ears. This appearance was relied on as a strong symptom of strangulation in the Kirwan case (ante, p. 747.) Dr. Geoghegan has informed me, that in one case of suicidal strangulation which he examined the constriction had been produced by a ribbon, and the violence applied was sufficient to produce bleeding from one ear. On dissection this was found to have resulted from a rupture of the membrane of the drum of the ear. There was no froth at the mouth or nostrils, and scarcely any lividity,
or swelling of the face. It was further observed that the mark on the neck, which was deep, almost disappeared on the removal of the ribbon. Mr. Wilde, of Dublin, has also met with a case in which rupture of the membrane of the drum of the ear with effusion of blood was caused by strangulation. Bleeding from the ears as a result of rupture of the membrane of the drum must however be regarded as an exceptional appearance. Dr. Chevers does not mention it as having been noticed in any one of the numerous cases which he has collected in his Indian experience, although bleeding from the nostrils has been observed. (Med. Jur. for India, 1856, p. 374.) Without rupture of the membrane of the drum blood could not issue from the ears, and in order that this membrane should be ruptured, certain conditions not commonly met with may be required. With a probable exception to be hereafter mentioned, I am not aware that there is any well-authenticated instance in which effusion of blood was met with on the brain of a strangled subject. The organs of generation in the male and female may present an appearance of congestion similar to that which is met with in hanging. The appearances commonly presented in strangulation, are similar to those described by Mr. Rake, in a case of partial suspension. (See ante, p. 736.) In a case which occurred to Dr. Fuller, the body of a woman who had been homicidally strangled presented the following appearances. The skin of the head, face, neck, and chest, were darker than natural, and discoloured underneath, particularly the scalp. The brain was suffused by dark blood, the lungs gorged and dark, the bowels of a dusky red colour. The eyes were somewhat protruded and blood-shot, the lips swollen and darker than natural, the tongue slightly protruding between the teeth, and froth issuing from the nostrils. There was a mark of pressure behind the right ear, and other marks on the neck and chest, with discoloration of the muscles. (Chevers' Medical Jurisprudence for India, p. 378; see also p. 387.) The state of the hands and feet is not mentioned. Among the occasional appearances of violent strangulation may be mentioned, injury to the windpipe (post. p. 813). Several instances of laceration and rupture of the windpipe, are quoted by Dr. Chevers. (Op. cit. p. 381, 384.) In one instance the ossified thyroid cartilage had been broken and forced inwards, causing suffocation. (For an account of the appearances in a strangled body thirty-eight days after interment, see Henke, Zeitschrift, 1842, i. 236; ii. 310.)

It is always proper in suspected homicidal strangulation to examine the contents of the stomach for narcotic poison.

The medico-legal questions relative to strangulation are of the same nature as those which have been already discussed in treating of hanging. Thus, in examining the body of a person suspected to have been strangled, we may be required to answer the following question: —
Was death caused by strangulation, or was the constricting force applied to the neck after death?—The internal appearances of the body will yield no evidence whereby this question can be solved; but the external appearances are commonly less ambiguous than in a corresponding case of hanging. The ecchymosis about the depression on the neck, when a ligature has been employed, with the accompanying swelling and lividity of the face, are phenomena not likely to be simulated in a dead body by the application of any degree of violence. When the constriction is produced within a few minutes after dissolution, an ecchymosed depression may result; but it is improbable that there should be any lividity or swelling of the countenance. The experiments of Prof. Casper, referred to in the section on hanging (p. 782.), bear directly upon the question which we are now discussing. He determined, from his observations, that when the constricting force was not applied to the neck until six hours after death, the mark indicative of vital strangulation could not be produced. The following is a summary of his experiments on strangulation in the dead body:

1. Six hours after death, a double cord was tightly drawn around the neck of a female, below the larynx. On the following morning the cord was loosened, and the neck examined. There was no particular appearance. When the skin had assumed its natural position, the part where the cord had been placed was scarcely distinguishable.—2. A man died of apoplexy, and thirteen hours after death a cord was drawn around the neck above the larynx, as tightly as possible. Six hours afterwards, on examining the neck, a soft impression, easily removed by pressure, was perceptible. There was no discoloration, nor any other change to be discovered in the skin.—3. Twenty-four hours after death, a double cord was very tightly drawn around the neck of a male subject. On examination the next day there was a slight double depression, but no colour nor any other perceptible change. This experiment was repeated on another subject, with similar results.—4. The last experiment was on the body of a child about one year and a half old. On the day after death, a small cord was tightly drawn and secured around the neck. Twenty-four hours afterwards, a slight bluish-coloured mark was perceived. It was quite superficial, but sufficiently distinct to strike the eye. On cutting into the skin there was not any blood effused beneath.

We learn from these experiments, that when the attempt to simulate strangulation in a dead subject is not made until six hours at least have elapsed, there is no risk of confounding the mark thus produced with that which is formed when the violence is applied to a living individual. It is probable, that so far as the ecchymosis is concerned, if the attempt were made after an hour or two hours had elapsed, it would wholly fail; and with
regard to the non-ecchymosed mark, it is very doubtful whether it could be produced after three or four hours. These periods, it must be remembered, are not settled with positive certainty: the results would probably vary, according to the degree of rapidity with which the body had cooled.

It is difficult to conceive under what circumstances an attempt to simulate strangulation in a recently dead body could be made, unless for the purpose of throwing suspicion upon an innocent person connected with the deceased. When an individual has been murdered, it is not likely that the murderer would attempt to produce the appearances of strangulation on a body after death, under the idea of concealing his crime; for strangulation is in most cases a positive result of homicide, and is very rarely seen as an act of suicide. In the absence of ecchymosis from the neck, it will be difficult to form an opinion, unless from circumstantial evidence. It must be remembered, however, that there may not always be an ecchymosed circle, for an individual may be strangled by the application of pressure to the trachea through the medium of the fingers, or of any hard or resisting material. The ecchymosis in such a case will be in detached spots. In the absence of all marks of violence round the neck, we should be cautious in giving an opinion which may affect the life of an accused party; for it is not probable that homicidal strangulation could be accomplished without the production of some appearances of violence about the larynx or trachea. It is doubtful whether strangulation ever takes place without some mark being found on the neck indicative of the means used. The bare possibility of death being caused in this manner, without leaving any appreciable trace of violence, must be admitted; although the admission scarcely applies to those cases which require medico-legal investigation. Suicides and murderers generally employ more violence than is necessary for the purpose of destruction; hence, detection is easy. But if a soft and elastic band were applied to the neck with regulated force, it is possible that an individual might die strangled, without any external sign being discovered to indicate the manner of his death. Indian surgeons inform us, that the Thugs, and other robbers met with in India, are thus accustomed to destroy their victims, with the dexterity of practised murderers. A case involving this question of strangulation without marks of violence, was tried in France, and from the medical evidence, decided in the affirmative. (Gaz. Méd. 9 Mai, 1846, 375.) The medical witness should, however, be prepared to consider whether, in the absence of any mark, death might not have proceeded from another cause, and leave it to the authorities of the law to decide from circumstances in favour of, or against the prisoner. There is, I conceive, nothing to justify a medical witness in stating that death has proceeded from strangulation, if there should be no
appearance of lividity, ecchymosis, or other violence about the neck or face of the deceased. Congestion in the organs of generation is an appearance which it would not be safe to take as evidence of death from strangulation. The state of the countenance alone will scarcely warrant the expression of an opinion; for there are many kinds of death in which the features may become livid and distorted from causes totally unconnected with the application of external violence to the throat unless accompanied by other well-marked signs of this mode of death. Let not a witness, then, lend himself as an instrument in the hands of counsel, for the condemnation of a person against whom nothing but a strong suspicion from circumstances may be raised, and where medical evidence is unable to throw any light upon the question of death having resulted from strangulation. (See the trial of Mrs. Byrne, for murder, Dublin Commission Court, Aug. 1842.) This trial is full of interest to a medical jurist. Some changes in the dead body appear in this case to have been mistaken for marks of strangulation.

**Marks of violence.**—It is scarcely necessary to state, that all marks of violence on the body of a supposed strangled person should be accurately noted, as the questions respecting them are material. The witness will be expected to state, whether they were inflicted before or after death: if before, whether they were sufficient to account for death, or whether they were such as to be explicable on the supposition of an accidental, suicidal, or homicidal origin. It should be observed whether there exist any morbid changes, sufficient to account for death, in either of the three great cavities of the body, as this kind of evidence may be very essential in the progress of the case.

**Was the strangulation the result of accident, suicide, or homicide?**—Strangulation, like hanging, is occasionally the result of accident; but the occurrence may be looked upon as rare. When the body is not suspended, it is commonly more in the power of an individual to assist himself, and escape from the constriction: hence accidental strangulation is less frequent than accidental hanging. A few instances of accidental strangulation are on record. One is reported by the late Dr. Gordon Smith. The subject was a boy, who was accustomed to move about with a heavy weight, suspended by a string round his neck. One day he was found dead in a chair. The weight appeared to have slipped, and to have drawn the cord tightly round the fore part of his neck. In June, 1839, a girl was accidentally strangled in the following manner: — she was employed in carrying fish in a basket at her back, supported by a leathern strap passing round the fore part of her neck, above her shoulders in front. She was found dead, sitting on a stone wall; the basket had slipped off, probably while she was resting, and had thus raised the strap, which firmly compressed the trachea. A similar case is recorded
by Watson (On Homicide). There will be no difficulty in deciding a question of accidental strangulation from the sight of the body and the means of constriction. Should it happen, however, as it is not unlikely, that the body has been removed from the position in which it was first discovered, we can only establish a presumption of accident from the description given by those who first discovered it.

When a charge of murder is instituted against a person, an attempt is not unfrequently made by counsel for the defence, to show the probability that the deceased might have fallen while in a state of intoxication, and have become accidentally strangled by a tight cravat, or by some foreign substance exerting pressure on the trachea. If we admit the possibility of an occurrence of this nature, we must not lose sight of the existence of other more probable modes of death, nor should we allow our judgment to be so swayed as to abandon what is probable for that which is merely possible.

Suicidal strangulation.—This mode of suicide must be regarded as of extremely rare occurrence, and except under particular circumstances, impossible. The possibility of an individual strangling himself was for a long time denied by medical jurists; for it was presumed that when the force was applied by the hand, all power would be lost so soon as the compression of the trachea commenced. This reasoning, which is physiologically correct, is, however, only applicable to those cases in which the windpipe is voluntarily compressed by the fingers. When an individual, determined on suicide, allows the windpipe to be compressed by leaning with the whole weight of his body on a ligature passed round his neck and attached to a fixed point, he may perish in this way almost as readily as if he had hanged himself; for insensibility and death will soon supervene. In the chapter on Hanging, it was stated that suicides were often found with their bodies in close contact with the ground; and cases were referred to in which strangulation was accomplished in the manner above described, while the suicide was in a sitting or kneeling posture. On other occasions, the peculiar disposition or nature of the ligature has enabled a person bent on suicide to strangle himself without much difficulty. An instance is related by Orfila, in which two cravats, that were twisted several times round the neck of the deceased who was discovered lying on his bed, had effectually served the purpose of self-destruction. (Méd. Lég. ii. p. 389.) Sometimes strangulation has been suicidally effected by a rough cord passed repeatedly round the neck, and tightened by being pulled with each hand. The number of coils would cause the pressure to be exerted even when the grasp was relaxed by death. (See Guy's Hospital Reports, Oct. 1831.) Other cases are related, in which suicides have succeeded in strangling themselves by tightening the ligature with a stick.
Guy's Hospital Reports, Oct. 1851); or where this was formed of thick and rough material, by simply tying it in a knot. A young female of Montevrin, in the Canton of Lagny, was found one morning, dead in bed, lying on her face, with a woollen garter passed twice round her neck, and secured in front by two simple knots, strongly tied the one on the other. The body was in an incipient state of putrefaction, but still there was a mark corresponding to the ligature. This was shallow, of a slight greenish colour, especially in front, and presented here and there ecchymosed spots; posteriorly the mark was scarcely visible. The face was livid and swollen: a quantity of sanguineous mucus escaped from the mouth and nostrils. The lips were livid; the tongue protruded, and firmly compressed between the teeth: the body presented, over the trunk and limbs, patches of ecchymosis. On cutting into the mark on the neck, there was no extravasation, neither was there any apparent injury to the deep-seated muscles or adjacent parts; the lungs were gorged with blood, but the other viscera of the body presented no particular appearance. The medical examiners gave it as their opinion, that the deceased had died from apoplexy resulting from strangulation. They stated that the head was not examined, and they judged that apoplexy was the cause of death, from the condition of the face. A more important question was, whether the strangulation was suicidal or homicidal. There was some reason to suspect the latter, and indeed a person was pointed out as the probable murderer: but a rigorous medical investigation, relative to the state of the body and clothes, as well as numerous collateral circumstances, satisfactorily established that this was an act of self-destruction. (Ann. d’Hyg. 1829, ii. 440. See also a case by Dr. Simeons, Henke, Zeitschrift, 1843, i. 335.)

Sometimes the appearance of the mark on the neck will allow us to establish a slight presumption for or against homicide. In homicidal strangulation, from the unnecessary violence used, we may expect to find the skin much ecchymosed, lacerated, or excoriated, and the deep-seated parts, such as the muscles and vessels, as well as the windpipe itself, more or less bruised, lacerated, or extenively injured. Such violence is not commonly to be expected in suicidal strangulation.

Supposing the marks of fingers to exist, the presumption is in favour of homicide; as also in all cases where the cause of strangulation is not at once apparent on the discovery of the body. Suicides are not likely to strangle themselves in any other manner than by a ligature applied circularly. If the ligature be still around the neck of the deceased, the position of the knot may throw some light upon the case: if tied in two or three knots at the posterior part of the neck, the presumption is assuredly in favour of homicide. Then, again, the nature of the ligature should be attended to. Suicides generally employ those articles
for ligature which are nearest at hand,—such as cravats, stockings, or garters. Some medical jurists have attempted to limit the varieties of suicidal strangulation; contending, that when a subject is found strangled in any other way than in one of those arbitrarily laid down by them as essential to suicide, it is evidence of murder. The fact is, cases as yet are few, and each new instance of suicidal strangulation presents us with something novel in the means of its accomplishment; a sufficient proof, therefore, that we ought to be very cautious how we decide these questions by hastily preconceived rules.

The mode in which the notorious criminal, Greensacre, attempted to destroy himself by suicidal strangulation, presented some novelty; and certainly it does not fall within the methods which, according to some medical jurists, suicides ought on these occasions to adopt. When, in March 1837, he was confined at a Station-House, he was found by the inspector, who entered the room, lying on the floor, with a handkerchief drawn tightly around his neck by means of a loop, into which he had inserted his foot. When first seen, his face was livid, and he was apparently dead: the handkerchief was cut, and vena section, with other means of resuscitation, were employed with success. The manner in which General Pichegru was found strangled in prison, gave rise to a strong suspicion of murder, merely from the singularity of the method adopted. The ligature which he employed was found tightened around his neck by means of a stick, which had been twisted, and then fixed behind one ear. There was no lividity of the face. It was contended, that Napoleon had caused the General to be strangled or suffocated, and that the ligature was afterwards applied. The evidence of this having been an act of homicide, is very weak; and so far as the medical circumstances extend, there is no reason to doubt that it was an act of suicide. The only obstacle to the admission of this, in the opinion of some jurists, was the employment of a stick for the purpose of tightening the ligature; but there are at least two similar cases on record, in which a suspicion of murder could not be entertained: one of these is referred to by Metzger (Op. cit. p. 309,) and another is recorded in Guy’s Hospital Reports for October 1851. There may be disease, such as paralysis, or deformity in one or both of the upper extremities, which may render it impossible for an individual to tie a ligature around his own neck. The only caution here to be guarded against, is that we do not push this doctrine too far. When there is a fixed resolution, many apparent impossibilities may be overcome by a person bent on suicide. The following case is, in this respect, instructive. A middle aged woman was brought into the Hôtel-Dieu, March, 1833, labouring under such a degree of mental excitement as almost to amount to insanity. Very soon after her admission she destroyed herself by strangulation. The nurse, in
going round the ward, saw her lying at the side of the bed with her head hanging out. Upon examination, it was found that she was quite dead, and that there was a silk handkerchief around her neck. The handkerchief had been carried twice round the neck, and then tied in front. The eyes and eyelids were strongly reddened and swollen. The mark of the ligature around the neck was deep, ecchymosed, and partially excoriated: the brain, though a little vascular, was healthy. The other viscera presented no appearance calling for notice. (Ann. d'Hyg. 1833, ii. 153.) It is worthy of remark, that in this instance, in which there could be no doubt of suicidal strangulation, the deceased had lost four fingers of her right hand, so that this member had been, from a very early period, of but little service to her; nevertheless she contrived to tie the cravat round her neck with great firmness and dexterity. It is easy to conceive that had her body been found in a suspicious locality, a plausible opinion of homicidal strangulation might have been formed from the maimed condition of her hand. This case, then, will serve to teach us a proper caution in drawing inferences as to what persons, labouring under any corporal infirmity, are capable of doing, when they make attempts on their own lives.

Although the cases just related show that suicidal strangulation may be effected under very singular circumstances, yet in a case of murder by strangulation, it would not be easy to simulate suicide: it would at any rate require as much skill and premeditated contrivance on the part of a murderer, so to dispose the body of his victim, or to place it in such a relation to surrounding objects, as to render a suspicion of suicide probable. Thus, if the ligatures should be found loose or detached,—if the ecchymosis or depression should not accurately correspond to the points of greatest pressure,—if, moreover, the means of compression were not very evident when the body was first discovered, and before it had been removed from its situation, there would be fair grounds for presuming that the act was homicidal. In those cases in which strangulation has resulted from compression of the windpipe by the fingers, and where there are fixed ecchymosed marks indicative of direct manual violence, we have the strongest presumptive evidence of murder; for neither accident nor suicide could be urged as affording a satisfactory explanation of their presence.

**Homicidal strangulation.**—Strangulation occasionally comes before our Courts of law as a question of murder: and when a party has been tried upon a charge of this kind, the circumstances have been commonly so clear, as to have rendered the duty of a medical witness one of a simple nature. Difficulties, however, occasionally arise, as may be seen by reference to the cases of the Queen v. Taylor (York Lent Assizes, 1842), and the Queen v. Greek (Salisbury Lent Assizes, 1843). See also the important case of the Queen v. Reynolds (Central Criminal Court, Dec. 1842).
Here it was left uncertain by the medical evidence, whether death was due to strangulation, or malicious exposure to cold; and as the indictment only charged the former act, the prisoners were acquitted! See likewise the case of Queen v. Fourles (Staff-f. Lent Assizes, 1841). For a full report of a case in which the question was, whether the deceased had committed suicide by hanging, or had been strangled by her husband, I must refer the reader to Cormack’s Journal for 1844, p. 344. The prisoner was acquitted on a verdict of “Not proven;” but there could be no doubt of his guilt. A case of alleged murder by strangulation (Commonwealth v. Flanagan), will be found reported in the American Jour. of Med. Sciences, Oct. 1845, p. 389. See also the case of Reg. v. Drory, Guy’s Hosp. Reports, Oct. 1851.

Cases.—The following case, reported in the Annales d’Hép. (1829, ii. 447), presents several points of interest in relation to this form of death. It was pronounced to be a case of suicidal strangulation by some, and of homicidal by others. A servant girl, far advanced in pregnancy, was found dead in her bed. According to the report of a surgeon who first saw her, the body was rigid, and there was a handkerchief so firmly tied around the neck, that it was with some difficulty removed. A quantity of air and bloody mucus escaped from the mouth and nostrils, on its removal. The body of the deceased, when first seen, was lying in a constrained position, with the face turned to the right. The knot in the handkerchief, which was tied round the neck, was on the left side, as it is customary to find it in left-handed people. This remark was particularly made by the surgeon, who happened to be himself left-handed. The deceased was not left-handed; and there was no reason to suspect that she had intended to commit suicide. She went to bed the night before in her usual health and spirits. On examination of the body, no marks of violence were seen externally: but there were large patches of cadaveric ecchymosis scattered over the skin. There was a deep impression of a necklace on the skin of the neck, which had resulted, it was supposed, from the force with which the handkerchief had been tied. The neck appeared swollen, especially on the right side. On opening the cranium the cerebral vessels were found much distended, especially on the right side; and on this side about half an ounce of blood was extravasated. In the mouth, the tongue projected forwards between the teeth, but was uninjured by them. The viscera of the chest and abdomen presented nothing unusual: the lungs were gorged with blood, as they are generally found in asphyxia. The examiners attributed death partly to apoplexy, and partly to interrupted respiration, in consequence of the ligature on the neck. They considered that the strangulation was not suicidal for the following reasons:—1. The handkerchief was tied in two knots, and the deceased could not have made more than one; her
sense would have failed her before she could have made a second; or at least before she could have made it so perfect as the first.

2. If she had strangled herself, the knot of the ligature would rather have been on the fore part of the neck, and on the left side.

The position in which the body was found, the cheerful conduct of the deceased on the night before her death, and the absence of all motive to induce her to commit suicide, were facts also dwelt upon by the examiners;—but they are manifestly of less weight than the two first assigned. Strong suspicions fell upon a man with whom the deceased had cohabited. He was arrested and charged with the murder. He gave a very unsatisfactory account of himself, but it was clearly proved that he could not have been at the house of the deceased on the night on which her death took place. It was also shown that he was not left-handed. The prisoner on this evidence was liberated. The master, in whose house the deceased lived as servant, was left-handed: but there was no reason to suspect him of the crime. Other witnesses deposed that they saw no one in or near the house on the night of the supposed murder, and in consequence of no other clue being discovered, and all means failing to find out the presumed murderer, it was ordered that the medical facts of the case should be reconsidered.

Some were inclined to believe that the deceased had destroyed herself, others that she had died a natural death. The College of Brunswick was appealed to by the legal authorities, to express a formal opinion from the medical facts, whether the deceased had been murdered by strangulation, or whether she had died from natural causes. The question of suicide appears to have been wholly abandoned. The College decided, that the deceased could not have died by strangulation; because there was no ecchymosis (blue mark) produced on the neck by the handkerchief. They assigned apoplexy as the probable cause of death, from the effusion of blood met with in the right hemisphere of the brain. They considered that the girl had herself tied the handkerchief round her neck, for the purpose of keeping herself warm, as the night on which she had died was extremely cold. They admitted the probability that she might have imprudently tied the handkerchief too tightly:—a circumstance which had perhaps facilitated the congestion of the cerebral vessels and extravasation of blood.

The opinion expressed by the College was drawn up at a time when it was universally believed that the mark of the cord, in the strangulation of a living person, was always accompanied by ecchymosis; and that the non-discovery of this was a sufficient proof of strangulation after death. The error of this opinion has been already sufficiently exposed (pp. 777, 781):—therefore the argument, that the deceased had not died by stran-
gulation, falls to the ground. The reason assigned for the handkerchief being placed around the neck, appears wholly inconsistent with the facts. It is scarcely to be imagined that any person who did not contemplate suicide, would retire to rest with a handkerchief tied in a double knot so tightly around the neck, as to render it very difficult to remove. It was evidently so tight that strangulation might easily have resulted from the constriction. The apoplectic appearances in the head may really have been due to the impeded circulation of the blood, in consequence of the ligature:—at least, it is as easy to conceive this, as to admit that they should have arisen coincidently from spontaneous causes. There was, therefore, nothing to contradict the opinion of death from strangulation: no morbid cause capable of giving rise to sudden death (excepting cerebral extravasation, which has already been accounted for) was discovered in the body. Whether the ligature was placed round her neck by the female herself, or by a murderer, is a matter of doubt:—yet when we consider that there was nothing absolutely impossible in the act on her part,—that there were no appearances of violence about her person or clothes,—and no evidence of any individual having had access to the apartment,—it appears most probable that the strangulation was suicidal. Some remarkable cases of homicidal and suicidal strangulation are reported by Casper. (Ger. Leich-Oeffn. 1853, i. p. 79; ii. p. 96, et seq.)

Within a recent period several important cases of murder by strangulation have been brought to trial in this country. In two of these, I was required to investigate the circumstances, and give evidence respecting the mode in which death took place, and the medical reasons which led to the inference that the deceased persons could not have died by their own hands. For a full report of one of these cases (Reg. v. Drory, Essex Lent Assizes, 1851), I must refer the reader to the Guy’s Hosp. Rep. Oct. 1851. The deceased in this case was found lying upon her face strangled, with a rope coiled three times round her neck, the two inner coils being tight and the outer coil loose, the end of the cord being placed loosely near the left hand of the deceased, which was raised towards it. The length of the free portion of cord was not sufficient to allow of the deceased grasping it and tightening it to such a degree as to produce the great amount of violence found on the neck. This, with other facts, tended to prove that the act must have been one of murder. In another case, Reg. v. Pinckard, Northampton Lent Assizes, 1852), it was proved that deceased was found sitting in a corner of her room, with a narrow tape round her neck, hung loosely and singly over a small brass hook about three feet above her head. Her clothes were placed smoothly under her, and her hands stretched out by her side. There was a severe bruise over the right eye, and there were marks of blood on the tape, as well as on the floor and wall.
of the room at a distance from the body. There was a stain of blood on the knot of the tape where it passed over the hook; and there was no blood on the hands of the deceased. The windpipe for about an inch and a half was lacerated longitudinally in its rings, and there was a deep mark round the neck in the course of the doubled tape, as if from great pressure applied by some person, or from the weight of the suspended body. The latter hypothesis was untenable. The body of the deceased did not weigh less than 126 pounds, while the tape found round her neck broke with a weight of 49 pounds: hence the deceased could not have been suspended by it. This fact, with the smooth arrangement of the clothes, the severe marks of violence on the body (inexplicable on the hypothesis of suicide), and the marks of blood and struggling in the room, proved that there had been homicidal interference; and the crime was brought home to the prisoner by a series of moral and circumstantial proofs. Both of these criminals confessed their crimes before execution. [The reader will find other reports of cases of alleged death from homicidal strangulation in the Med. Gaz. vol. xli. p. 295; and vol. xlv. p. 1084.]

In directing attention to circumstantial evidence (ante, page 793.), it was suggested that the dress of the deceased might be torn or decomposed, a fact indicative of a struggle, and, ceteris paribus, incompatible with suicide; but it is proper to remark that evidence of murder, as in Pinchard’s case, may be obtained, by finding a smooth and undisturbed state of the dress, as well as by the attitude of the body. In fact, whosoever attempts to imitate suicide under such a form of murder, must, when the facts are properly investigated, inevitably fail. The assassin either does too little, or he does too much. The woman who committed the murder in Pinchard’s case, had been a nurse in an Infirmary, and accustomed to lay out dead bodies. After the murder, she appears to have carried out unthinkingly her professional experience, by smoothing the clothes under the body, placing the legs at full length, the arms out straight by the side, and the hands open and laid out! Such a condition of the body was quite inexplicable on the supposition of suicide, considering the amount of violence which must have attended the strangulation. In the case of Drory, the murderer had attempted to make the death appear like an act of suicide by placing the lower end of the rope near the hand of the deceased: but he selected the left hand when the deceased was right-handed, and he did not leave enough rope free from the neck for either hand to grasp in order to produce the violent constriction observed!

It is proper to notice, in this place, the frequent occurrence within the last few years of what are called "Gadotte robberies." The system of murder pursued by the Thugs in India, appears to have been imported into England, and many lives have been de-
stroied in the manufacturing districts and in large towns by the employment of strangulation as a means of robbery. In spite of some convictions, the greater number of criminals have hitherto escaped the penalties of the law. The attack is made during darkness: the person is seized by the windpipe from behind, a bandage is thrown around his neck, and this is suddenly tightened while accomplices are engaged in perpetrating robbery. The person assaulted, if he should recover, is seldom able to identify an assailant,—he is rendered immediately senseless and powerless: he can give no alarm, and he can offer no resistance. Recovery or death in such cases depends on the lapse of a few seconds more or less, during which the constriction of the neck is continued,—on the degree of constriction, and on the age, sex, and strength of constitution of the person assaulted. There appears to be no law which is sufficient to meet this crime with appropriate severity. The 1 Vict. c. 85, s. iii, makes it felony to attempt to strangle with intent to commit murder, and the 14 and 15 Vict. c. 19, makes no provision for the crime. The intent in these cases is to commit robbery, and not murder: this is an accidental result, for which the assailants, if detected, can be punished. But it is desirable to put an end if possible to a means of perpetrating robbery which places a man in the greatest jeopardy of his life, which deprives him of all power of resistance or of giving alarm, and such attempts should be treated as something more than assaults. The use of stupefying drugs to commit felonies is severely punished by the 14 and 15 Vict. 19, and the same punishment should be assigned to those who resort to partial strangulation for a similar purpose.

Marks of violence. — It may be inquired whether marks of violence on the body or blood-stains on the clothes or furniture, do not afford strong evidence of homicidal strangulation. The answer is—if the marks of violence be such that they could not possibly have arisen from any accident before death, or that they could not possibly have been self-inflicted, they afford the strongest evidence of murder. But the cases wherein no positive answer may returned, are the exceptions to the rule. It is not always in our power to distinguish accidental or self-inflicted, from homicidal violence; and we are always bound to look to the possibility of accident, or of previous attempts at suicide, being the source of those personal injuries which may be apparent on a strangled subject.

In the following case, communicated to me by Dr. Campbell of Lisburn, the marks of injury to the neck clearly established homicidal strangulation. The dead body of an old man, aged 70 years, was found lying in a potato-field adjoining his house, on the 10th of October, 1842. His family consisted of a son, the son's wife, and a male servant, brother to the son's wife. The deceased had gone to gather potatoes for the servant who was
digging. On its being known to their neighbours that the body had been found in the field, suspicions were excited that his death had resulted from violence. An inspection of the body was ordered. The depending parts were very livid, owing to their position. On opening the skull, a large quantity of dark fluid blood escaped; the membranes of the brain were greatly injected, the sinuses gorged with blood, and the brain itself was highly congested. Several clots of blood were observed in the lateral ventricles, and some over the surface of the brain. In the chest the lungs were filled with dark fluid blood, the air-cells were ruptured, and there was considerable emphysema. The right side of the heart was greatly distended with dark blood; there was nothing remarkable in the abdominal viscera, but the lining membrane of the stomach was congested. The stomach was about half filled with potatoes. On the neck, over the left wing of the thyroid cartilage, there was a slight mark of a crescentic form, with a corresponding though slighter mark on the opposite side; and on removing the skin over these marks a considerable amount of coagulated blood was seen immediately beneath, and in the substance of the muscles. On removing this, the left wing of the cartilage, which was ossified, was found much depressed, and traversed by a fracture nearly an inch in length. From the general appearances presented by the body, together with the injury to the thyroid cartilage, an opinion was given that death had arisen from manual strangulation,—and from the particular form of the external marks over the neck,—by a left-hand. Several witnesses were examined, who proved that the deceased and the servant were on bad terms, the deceased having threatened to dismiss the servant, and that before they had gone to dig the potatoes, the servant said he would be revenged of his master. The servant was committed for trial at the ensuing assizes. One of the magistrates present desired that the prisoner might be requested to throw a stone, in order to ascertain if he was left-handed, which he did with the left hand. At the trial, the sister of the prisoner swore that she saw her brother strangling the old man; and several witnesses proved that he had maltreated the deceased on many previous occasions. The counsel for the defence advocated the prisoner's case so well, and proved the sister to be of so improper a character, that the jury, having some doubt as to her veracity, acquitted him. Dr. Campbell forwarded to me the larynx, which was ossified, and fractured in the ossified portion, as described in the report of the case.

There may be several marks on the neck; but then the person may have tried to strangle himself more than once. The throat may be cut,—there may be a deep-seated stab or gun-shot wound, involving some of the important organs of the body, or poison may be found in the stomach;—but in a purely medical point of view, how are we to know that the deceased did not
actually inflict the wounds upon himself, or take the poison before making the attempt? In the chapter on Drowning and Hanging, we have seen what suicides can do, when they are desperately bent on destroying themselves. These injuries often create serious difficulties to a medical jurist, which it requires the greatest caution and prudence on his part to meet and explain. The prejudice of the public mind is such, that the discovery of a strangulated person, with marks of personal injury or of poisoning in his stomach, would, in most cases, lead to a declaration of murder, unless the facts rendered it clearly impossible that an attempt could have been made on his life. It is against this prejudice that a medical witness must strenuously guard himself:—he may be abused for not joining in the outcry of the vulgar; but the best recompense for this abuse will be the conviction, that he is interposing the shield of science to protect a possibly innocent fellow-creature from the senseless denunciation of ignorance.

A case was tried at the Northampton Lent Assizes, 1853, (Re v. Gibbins) which presents some features of interest. The prisoner was charged with the murder of a boy aged 8, her illegitimate son. He was alive and well at about 4.30 in the afternoon, at which time he was taking tea with the prisoner and her sister. A little before eight o'clock in the evening, he was found dead in his bed, lying on his back with his arms across the lower part of his chest. A silk handkerchief was tied tightly round his neck, and the bed-clothes were a little turned off him. There was a mark or depression round the neck where the handkerchief had been tied, but no ecchymosis beneath. The brain and its membranes were much congested; the lungs slightly congested; the stomach contained some food partly digested; the mucous membrane is stated to have been found considerably inflamed (?) and the inflammation extended to the upper part of the small intestines. One medical witness said, that taking into consideration the fact of the handkerchief being found round the neck, and the position of the body, he was of opinion that death was caused by violence (strangulation); and he did not think that the boy could have strangled himself. If he had tied the handkerchief tight enough to produce strangulation, he could not have returned his hands to the position in which they were found. Another medical witness considered that deceased had died from poison. He formed this conclusion from the extensive inflammation of the stomach and intestines, and from the absence of any other cause sufficient to account for death. He did not think the congestion of the brain was sufficient; nor did he think that the deceased had died from strangulation. There was an absence of the usual mark (ecchymosed ?), and the face was pallid; the congestion of the lungs was slight, and there was no blood in the right cavities of the heart. A chemist stated that he had examined the con-
tents of the stomach, but there was no mineral poison; the inflammation of the stomach might have arisen from poison, or from natural causes. As the medical evidence entirely failed to prove that the deceased had died from violence, the prisoner was acquitted.

It is not at all probable that in this case the appearances in the stomach were the result of inflammation from irritant poison. Any irritant, mineral or vegetable, which would have destroyed life in three and a half hours, without causing vomiting and purging, would have been found in the stomach. The partly digested meal taken at 4.30, when the boy was seen healthy and well, was there found unmixed with any poison. How, and when, was the silk handkerchief tied round the neck? It was not the result of accident, nor could suicide be suspected in a boy aged 8. The attitude in which the body was found, and the age of the child, are adverse to the supposition of suicide. The handkerchief was not tied round the neck after death; there could be no motive for such an act. It must have been tied while the child was living. The absence of any ecchymosis in the course of the ligature is not opposed to this view. The state of the brain appears to show death from apoplexy as a result of an interruption to the cerebral circulation by the ligature. The usual appearances of asphyxia were wanting. The redness of the stomach was probably owing to congestion, and not to inflammation, and may have been due to the process of digestion going on at the time of death, or it may have been the result of congestion, as observed by Dr. Yellooly in the bodies of executed criminals, and by others in cases of strangulation (ante, p. 776). There can be no doubt, that, taking all the circumstances, this was a case of homicidal strangulation, the fatal effects being produced through the brain, and not through the heart and lungs. For the particulars of this case I am indebted to Mr. Burton of Daventry.

It cannot be disputed that in contested questions of suicidal or homicidal strangulation, rare as they are, we must be often greatly indebted to evidence founded on circumstances, as well as to moral presumptions. How far a medical jurist may be allowed to make use of these in the formation of an opinion, it will be for the Court to determine. Generally speaking, his duty is rigorously confined to the furnishing of medical evidence from medical data alone; but instances present themselves in which this rule must be departed from, or the course of justice will be impeded. Besides, there are numerous circumstances of a collateral nature which may materially modify a medical opinion. Thus, the sight of a ligature, the state of the dress, and the attitude of the deceased when discovered, although not strictly medical circumstances, bear directly upon them; and that evidence ought not to be objected to which is partly founded upon facts of this nature. It must occur to all, that without cir-
cumstantial evidence, the best medical opinion in these cases will	en often amount to nothing. It may be, for example, no more than
this: the case is either one of homicide or suicide; and why is
such an indefinite answer to be returned? Because, in the
abstract view of strangulation, it is not easy to determine whether
a ligature was suicidally applied round the neck or not. The
appearances may be in many cases the same; and where they
are different, this difference may be due to accident: so that it
is a mistake to suppose that we must look to medical cir-
cumstances alone for clearing up this intricate question. On
some occasions the theory of homicide or suicide will equally
suit the facts. The cases of Dr. Franck and his son, which
occurred at Brighton in November, 1855, were of this ambiguous
character. Whether the son strangled himself or was strangled
by his father, were questions which could not be satisfactorily
solved by medical, moral, or circumstantial evidence. Unfor-
tunately, the bodies did not undergo a proper medico-legal in-
spection.

There is, perhaps, one instance which may justify a presump-
tion of homicide. A man, in strangling himself, is not likely to
vary the means: it is commonly due to a sudden impulse, if we
may judge from the moral proofs afforded in the instances on
record. The article which is nearest to the suicide is seized, and
made the instrument of destruction. It has already been stated
as doubtful whether a person could strangle himself by the mere
application of the fingers to the trachea: the discovery of such
marks only as would indicate this kind of strangulation, there-
fore, renders suicide in the highest degree improbable. But these
marks may be sometimes ascribed to the deceased having fallen
with his hand possibly applied to his neck, and the inference will
be drawn that they have accidentally resulted from the pressure
of his own fingers. This is a very improbable mode of account-
ing for the production of ecchymosis or excoriation of the skin.
If, besides these marks of fingers, we find a circular mark, with a
ligature still around the neck, the presumption of murder be-
comes, indeed, strong. It may be said, that an individual might
first try to strangle himself with his fingers, and, not succeed-
ing, might afterwards employ a cord. But the degree to which
the coincidental impressions exist will assuredly in general re-
move this objection. A murder was committed some years since
in this country in the manner here stated. A gentleman of fortune
was found strangled on board of a ship in the port of Bristol.
Besides the mark of a rope drawn tightly round the neck, there
were distinct impressions of nails and fingers in front of the
throat. An investigation took place, and the result proved, as,
indeed, this state of the neck rendered it almost certain, that
the deceased had been murdered. It was afterwards confessed
by one of the murderers, that they had first strangled him with
their hands, and then drew the rope about his neck, to insure the certainty of his death.

In concluding this account of strangulation, it may be remarked, that attempts are sometimes made to attribute traces of violence on the neck to accidental causes, notwithstanding the almost entire certainty of their being homicidal. Thus, when a man is found dead with a mark on the neck, it will be argued that the deceased might have fallen while in a state of intoxication, and have become strangled by his cravat, his head being at the same time bent forwards. The witness will be asked whether death from accident was not possible under such circumstances. In returning an answer, he should take care to let it be understood, that what is physically possible is not always medically probable.

---

**SUFFOCATION.**

**CHAPTER LXI.**

**SUFFOCATION FROM MECHANICAL CAUSES — VARIOUS FORMS OF — CASES—CAUSE OF DEATH—APPEARANCES AFTER DEATH — EVIDENCE OF DEATH BY SUFFOCATION — ACCIDENTAL, SUICIDAL, AND HOMICIDAL SUFFOCATION — MEDICAL AND PHYSICAL EVIDENCE OF THE CAUSE OF DEATH — CASES — SMOOTHERING.**

_Suffocation from mechanical causes._—By suffocation we are to understand that condition in which the air is prevented from penetrating into the lungs, not by constriction of the trachea, but by some mechanical cause acting on the mouth externally, or on the fauces and larynx internally. In this sense, it will be perceived that drowning is nothing more than death by suffocation.

There are many varieties of death by suffocation, all of which are of great medico-legal interest. 1. The continued pressure of the hand over the mouth and nostrils, or the placing of a plaster or cloth over these parts, combined with pressure on the thorax; this was formerly not an unfrequent form of homicidal suffocation. 2. Smothering, or the covering of the head and face with articles of clothing, &c., which effectually prevent respiration. 3. The accidental or forcible introduction of foreign bodies into the mouth and throat. 4. The plunging of the face into mud, snow, dust, feathers, or similar substances. In all of these
cases death takes place from asphyxia, and with great rapidity if
the chest sustains at the same time any degree of forcible com-
pression. 5. Swelling or spasm of the glottis produced by the contact of corrosive substances. A case was referred to me in July, 1848, in which death was probably thus caused by the application of a strong solution of pernitrated mercury to an ulcer in the fauces.

Suffocation may also arise from morbid causes; such as a diseased state of the parts about the fauces, a morbid enlargement of the thymus or other glands, the sudden bursting of a tonsillar abscess, or the effusion of lymph, blood, or pus into the windpipe, or about the rima glottidis. Any of these causes may suddenly arrest the respiratory function; a fact which can only be determined by a proper examination of the body. Among many cases of death from suffocation produced by mechanical causes which have been reported, the following are deserving of notice.

1. A boy died in half an hour under alarming symptoms somewhat resembling those of poisoning, and it appeared that a simple medicinal powder had been given to him about five minutes before the attack! On inspection Dr. Geoghagan found the lower part of the windpipe blocked up with cheesy scrofulous matter;—it was evident that the child had died from asphyxia as the result of disease, and not from the medicine. 2. The following case was communicated by Mr. Edwards to the Medico-Chirurgical Society. A child of eight years of age, while at play, was suddenly seized with symptoms as of a fit. He was quickly carried home; became violently convulsed; although retaining consciousness and the power of utterance, the countenance became extremely anxious, and he uttered the expression that he should die. In the hurry of the moment there was no opportunity of getting any distinct knowledge of the previous history, beyond the surmise that the boy had swallowed something. The trachea was immediately opened; a little air issued from the opening; artificial respiration was attempted, but without effect, as the child gave but two gasps after the operation, and died. An inspection revealed the presence of a foreign body in the upper part of the air passages. The substance was whitish, and covered with mucus. On examination it was evident that the body was a bronchial gland. Upon slitting open the windpipe, the spot whence the gland had issued was soon observed. 3. A man, aged 31, was put to bed drunk, having previously vomited; and shortly afterwards he was found dead. On inspection, Dr. Jackson of Leith discovered the usual appearances of asphyxia, i.e. congestion of the lungs and of the right cavities of the heart. He was thus led to examine the air-passages carefully, and he found, lying over the upper opening of the windpipe (rima glottidis), a thin and transparent piece of potato skin, so closely applied to the fissure as to prevent respiration.
ACCIDENTAL SUFIXICATION FROM FOOD.

The man had died suffocated from this mechanical cause. He had had potatoes for dinner the day before; the piece of skin had probably been thrown up at the time of vomiting, and had been drawn back by inspiration into the singular position in which it was found. Owing to intoxication, the deceased was probably unable to cough it up. I agree with Dr. Jackson in thinking that this case conveys a caution in making inspections. In England, the verdict would most probably have been, "Died by the visitation of God," without an examination of the body! The result clearly shows that in every case of sudden death there should be a strict investigation. (Ed. Med. and Surg. Journ. April, 1844, 390.) Dr. Richardson met with a case of death from suffocation, caused by the vomiting of the contents of a full stomach, a portion of the food having blocked up the throat. A case similar in its details occurred to Mr. Matthews. (Lancet, Aug. 31, 1850, p. 262.) Children are often suffocated from small portions of food penetrating into the air-passages, and unless an inspection of these parts is made, death may be easily referred to some natural cause. (See case by Mr. Synnot, Med. Gaz. xl. 994; and also Lancet, May 16, 1846, 561.) In some instances, a retraction of the base of the tongue may lead to the suffocation of a new-born child. (Sellar's Journal, March, 1854, 278.) Accidental suffocation from the impaction of large masses of food is by no means uncommon. If the glottis (the opening of the windpipe) be completely closed by food, death may take place very suddenly. It does not follow, however, that a person so situated is incapable of making some exertion, or of locomotion. Dr. Mackenzie relates a case in which a man was suddenly choked by swallowing a large piece of meat. He immediately walked across the street to a chemist's shop, and soon after entering it, he fell down in a state of asphyxia. After death, the fauces were found to be filled with a piece of beef, which rested on the glottis, and pressed the epiglottis forward. Part of the mass had entered the trachea through the rima glottidis. It is probable that in this and similar cases the foreign body does not so completely close the aperture as to prevent some degree of respiration, but the blood being imperfectly aerated, asphyxia is speedily induced. (See Ed. Monthly Journal, July, 1851, p. 68.) A person has been wrongly charged with causing the death of another, when the cause was really owing to the impaction of food in the air-passages. A remarkable instance of this kind occurred at Hillingdon, and is reported in the Lancet. (March 9, 1850, p. 313.) Deceased had had a quarrel with the accused, who was his son-in-law, and they were seen to fall to the ground together, while struggling and fighting. They were separated. About two hours afterwards, the deceased, who appeared quite well, was observed to rise from the dinner-table and leave the room. He was found leaning against the cottage.
as if in a falling position, and he expired in two or three minutes. The party with whom deceased had been fighting was charged with manslaughter before a magistrate. At the inquest, the medical witness stated that he found the organs of the body, excepting the brain, in a very healthy state. The brain was excessively congested, and he attributed death to apoplexy. Mr. Wakley desired the witness to examine the mouth and throat, (which he had omitted to do at the inspection,) as from the suddenness of death after eating he (the coroner) thought the man might have been choked. This opinion turned out to be correct. A large piece of meat was found wedged in the opening of the throat. This had caused death by suffocation. It had not completely closed the air-passage in the first instance; hence the man was able to move from the dinner-table. The person accused of manslaughter was discharged.

Cause of death.—It has been already stated that death takes place by anæmia or asphyxia; and this occurs with a rapidity proportioned to the degree of impediment existing to the passage of the air. There does not seem to be any reason to attribute death to apoplexy. The congestion of the cerebral vessels may be regarded as a consequence of the disturbance of the functions of the lungs. If the veins of the neck were opened so as to prevent an accumulation of blood in the cerebral vessels, it is pretty certain that the prevention of respiration would destroy life under the same circumstances and within the same period of time. Therefore we may regard death from suffocation as resulting from pure asphyxia.

Appearances in the body.—There are rarely any considerable marks of violence externally. When the body has become perfectly cold, there may be patches of lividity diffused over the skin; but these are not always present. The lips are livid, but the skin of the face is often pale. There is a mucous froth about the lips and mouth. The mouth, throat, and parts about the wind-pipe, should be examined for foreign substances. Internally the lungs and right cavities of the heart may be found distended with blood. The state of the heart and lungs may vary as in other forms of asphyxia (ante, p. 737). The abdominal viscera have been observed to present patches of lividity. Casper has found the kidneys more strongly congested with blood than the liver, spleen, and other organs. (Ger. Leich-Oeffn. 1853, 1, s. 78.) The vessels of the brain are sometimes congested; but at other times they do not appear to be more than ordinarily full. Their condition may be affected by the slowness or rapidity with which death takes place. All other appearances are of an accidental nature, and are not at all connected with death by suffocation. (See cases by Casper, Med. Gaz. vol. xlv. p. 1084; also a series of papers by Dr. B. W. Richardson, Med. Gaz. xlvi. p. 359, et seq.)
Evidence of death from suffocation. — In medical jurisprudence, there is not, perhaps, an instance in which we have fewer medical data upon which to base an opinion, than in a case of alleged death from suffocation. The inspection of the body of a person suffocated, presents so little that is peculiar, that a medical man, unless his suspicions were roused by circumstantial evidence, or by the discovery of foreign substances in the air-passage, would probably pass it over as a case of death without any assignable cause; in other words, from natural causes. In examining the body of the woman Campbell, who was murdered by Burke, in Edinburgh, Dr. Christison was unable to come to a conclusion respecting the cause of death until some light had been thrown on the case by collateral evidence. On this occasion a violent death was suspected, because there were marks of violence externally, and the face of the deceased exhibited the characters of strangulation; but these conditions are by no means essential to death from suffocation, and when they exist, they can only be regarded as purely accidental accompaniments. Appearance, similar to those found in the bodies of suffocated persons are very frequently met with in inspections when death has taken place as a consequence of disease or accident. They can, therefore, furnish no positive evidence of the kind of death; they do
not even permit us to establish a presumption on the subject, until, by a careful examination of the body, we have ascertained that there is no other cause of death depending on organic disease or on violence. Medical evidence may, however, be highly serviceable in some instances. Thus, let the general evidence establish that a deceased person has probably been suffocated,—the witness may have it in his power to state that the appearances in the body are not opposed to the supposition of this kind of death; that the body is in all respects healthy and sound; and that the death was probably sudden, as where, for instance, undigested food is discovered in the stomach. In all cases of this description, we must bear in mind that our opinion relative to the supposed cause of death is to be formed from the medical circumstances only, and from what we have ourselves seen, unless it be otherwise ordered by the Court. From this want of clear evidence, great difference of opinion on the case of death frequently exists among medical witnesses. In the case of Reg. v. Heywood (Liverpool Summer Ass. 1839), some of the witnesses referred death to suffocation, others to apoplexy. (Lancet, Sept. 14, 1839, 896.)

Accidental, suicidal, and homicidal suffocation.—Accidental suffocation is by no means uncommon; and there are several varieties of accident under which a person may die suffocated. 1. Disease about the tongue, larynx, or fauces, may advance to such an extent as effectually to impede respiration. 2. The deceased may have fallen, and the mouth become covered with dust or other substances: and if the subject be helpless, as in an infant or an aged person, or one who is intoxicated, death may thus easily take place. A child was found dead in a room, with its face in the ashes under a grate. It had fallen during the absence of the mother; and from its helpless condition, had speedily become suffocated. Some of the ashes were found in the wind-pipe. (Med. Gaz. xvii p. 642. For a case in which suffocation was caused by a pea, see the same journal, xxix. 146.) In trials for murder or manslaughter, a medical opinion respecting the possibility of the accidental suffocation of a drunken person, under similar circumstances, is very often required. These subjects, it must be remembered, are generally to be considered as helpless as children:—if they fall in a position so that the mouth is covered, it is possible that they may have been so intoxicated as not to be able to escape. 3. A portion of food may have remained fixed in the larynx or fauces. Children are often accidentally suffocated by drinking boiling water from a tea-kettle. The parts about the larynx then become swollen from the action of the hot water, and respiration is arrested. 4. Accidental suffocation is not uncommon among infants, when they sleep with adult persons. A child may be in this way very speedily destroyed. Even the close wrapping of a child's head in a shawl may
effectually kill it, without any convulsive struggles to indicate
the danger to which it is exposed (post, p. 829). Convulsions
by no means necessarily attend on death from suffocation.

A few years since a coroner’s inquest was held on the body of
a child, which was found dead in a bed; and I assisted a friend
in the inspection after death. It was lying in a composed
attitude on the bed with the face nearly covered. There were
faint traces of cadaveric lividity about the neck and back; but
the body did not present the least mark of violence. The face
was pale but the lips were livid. On examining the chest, the
great vessels connected with the heart and lungs were found con-
gested with blood. The vessels of the brain were empty. There
were no morbid appearances whatever in any of the other organs.
The account given by the girl who attended the child, was, that
she had laid it to sleep about nine o’clock in the morning, covering
over the greater part of its face. She remained in the room;
but in the course of an hour, not hearing the child breathe, she
looked and found it dead. The only opinion which we were asked
to give, was,—whether, from the circumstances, suffocation was
probable? We answered in the affirmative; and a verdict of
accidental death was returned. This case shows the ease with
which an infant may be destroyed, even when its respiration is
only partially impeded. The weight of the clothes may have
combined to cause death, by preventing the free expansion of
the chest.

Those instances of accidental suffocation which depend on
disease or on the impaction of food, are easily known by an ex-
amination of the body:—generally speaking they present no diffi-
culty. (See cases, ante, page 761; also Med. Gaz. vol. xlii. p. 970;
also Lancet, Sept. 2, 1848, p. 259.) But in other instances, e. g.,
when a child or a drunken person is presumed to have been suf-
focated owing to the position in which he has fallen, evidence
as to the position of the body, or even the actual sight of the
body, is necessary before forming an opinion. The following
questions may here arise:—Was the position such as to be
explicable on the supposition of accident? Was it not such a
position as might have been given to it by a murderer? Could
not the deceased have had strength or presence of mind to escape?
Could he have been actually suffocated in the position in which
his body was discovered; a little reflection upon the circum-
cumstances,—for here something more than medical circumstances
will be required,—may enable us to give satisfactory answers to
these questions.

A remarkable case of accidental suffocation was communicated
to me by a former pupil, Mr. Bake. A groom was found dead,
with his head downwards, in the iron rack used for feeding horses
with hay. His legs projected from the hole in the floor above.
The space was so narrow that there had been no room to turn,
and there was no fulcrum by which the deceased, who had the
fallen head downwards into the hole, could again raise himself.
There was no doubt that, in reaching into the hole, the deceased
had accidentally fallen head foremost into the rack in the midst
of the hay, and he had died in this position, without the power
to raise an alarm, or to make any successful effort for his ex-
citation. It is possible that homicide might be committed in this
way, but there was no reason to suspect it in this instance.

Suicidal suffocation.—As an act of suicide, suffocation is ex-
tremely rare. It would require a peculiar adaptation of means
and considerable resolution, in order that a person should thus
destroy himself. The following case occurred in France some
years since. A woman locked herself in her room with her
young child;—she placed herself under the bed-clothes, and
desired the child to pile the several articles of furniture in the
room upon her. When the apartment was entered some hours
afterwards, the woman was found dead. She had evidently been
suffocated. Had not the child clearly detailed the circumstances,
a strong and even a justifiable suspicion of murder might have
arisen. In the case of a body found with a plaster covering the
mouth and nostrils, or the traces of such having been applied,
the witness might be asked, whether this could have been so
placed by the individual himself? No such case has ever occurred
as an act of suicide; but we are not, therefore, to say it is im-
possible;—all that we are justified in stating is, that it is a highly
improbable mode of self-destruction.

Some singular cases are on record, in which persons have
willfully destroyed themselves by blocking up the passages me-
chanically. An instance of this form of suicide is reported
in prison, forced a hard cotton plug into the back of her throat.
The cavities of the chest and abdomen had been already examined,
and a medical certificate given that the deceased had died of
apoplexy! The body was sent to one of the anatomical schools
and on re-inspection, it was then accidentally found that the
throat was firmly blocked up with a plug of spindle-cotton. A
similar case was the subject of an inquest in London, in Sep-
tember, 1843. The deceased here had thrust into her throat a
large piece of rag, which had been used in applying a lotion.
She speedily died suffocated, and after death the rag was found
lodged at the back part of the throat. A case occurred at
Maidstone in July, 1856, in which a man confined as a prisoner
in a cell is reported to have committed suicide by suffocation.
He was found lying on his face dead. He had thrown his bed
on the floor, had filled his nostrils with pieces of rag, his mouth
with a handkerchief, and had tied another handkerchief over his
mouth, after which he must have thrown himself down upon his
face. The internal organs in these cases present no particular
EVIDENCE OF HOMICIDAL SUFFOCATION.

appearances indicative of the kind of death. Such cases are very likely to be mistaken for apoplexy, and they certainly show the absolute necessity for a careful examination of the mouth and air-passages, in every instance of sudden death. (See Ed. Med. and Surg. Jour. liv. 149; also, Med.-Chir. Rev. xxviii. 410.)

Homicidal suffocation.—Homicide by suffocation is not very common, although it is a very ready means of perpetrating murder. Hitherto, the cases which have come before our Courts of law have been those of infants, of the aged and infirm, and of persons enfeebled by illness. In regard to the latter subjects, the rigorous administration of the law has succeeded in putting a check to this crime: but with respect to children, it probably yet continues. Infanticide by suffocation is most difficult to detect; and, unless the murderer has employed a very unnecessary degree of violence, it is probable that the crime may pass altogether unsuspected. The case of Reg. v. Heywood, Lancaster Sum. Ass. 1839, proves how easily a defence of apoplexy may be sustained in a case of alleged murder by suffocation.

Homicide by suffocation would not be attempted on healthy adult persons, unless they were in a state of intoxication and thereby rendered defenceless. It is certain that most individuals would have it in their power, unless greatly incapacitated by disease or intoxication, to offer such a degree of resistance as would leave upon their persons indubitable evidence of murderous violence. Death by suffocation may be considered as presumptive of homicide, unless the facts be clearly referable to accident. Accidental suffocation is, however, so palpable from the position of the body and other circumstances, that when death is clearly traced to this cause, it is not easy to conceive a case in which it would be difficult to distinguish it from a case of actual murder. In some instances, the very means that have been adopted to produce suffocation, may forbid the supposition of accident, and clearly establish the fact of homicide.

M. Duffereje has reported a case, in which a man was suffocated by having his face forcibly thrust into a heap of corn. A quantity of the corn was found blocking up the mouth and nostrils, and some of the grains had passed into the air-passages (drawn into those parts by forcible inspiration,) as well as into the stomach by swallowing, and even into the duodenum. That violence had been used was proved by the marks of indentations produced by the grains of corn on the face, as well as by excoriations (indicative of resistance) on the hands. The facts were quite inconsistent with the supposition of suicide or accident; yet the jury declined to accept the medical opinion, that the deceased had been homicidally suffocated. (Ann. d'Hyg. 1852, ii. 195.) The presence of the grains of corn in the duodenum is not easily to be explained, considering the rapidity of death from suffocation, and that they could not be carried to the small
intestine either by aspiration or deglutition. The power of aspiration in the chest is exceedingly great, and drunken or helpless persons may, by falling in the midst of dust, ashes, or other substances, draw a portion of these substances into the air-passages, and thus die by suffocation. In the paper above referred to, M. Devergie mentions the case of a man who fell asleep near some sheaves of corn. He was found dead, and the case of death was obviously asphyxia. An ear of corn was found fixed in the air-passages.

The suffocation of new-born children, by the introduction of substances into the mouth, is not unfrequent. (See ante, Infanticide, p. 494.) The unnecessary force employed generally leaves traces of violence, which may be easily discovered by a careful examination, even should it happen that the substance used for the murderous purpose has been removed. M. Devergie has suggested an objection to evidence founded on a fact of this nature, that the substance might have been introduced after death in order to create a suspicion of infanticide against the mother; but such an objection could hardly be received, since the fact is only one out of many which would be brought against an accused person. According to Devergie, the appearances produced by the introduction of a plug of linen into the mouth during life, are these—the mouth contracting posteriorly, the pressure would be greater in this situation, consequently the blood would be forced out of the compressed mucous membrane of the palate. Anteriorly, the pressure would be less; and here the blood would accumulate, so that the mucous membrane in this situation would become swollen and red. In trusting to these characters, it must be remembered that similar appearances would probably result if the plug were introduced immediately after death, as, also, that even when introduced during life, the characters might be lost if the plug were removed from the mouth before the body had entirely cooled.

It is necessary to point out a very dangerous practice common among ignorant nurses, which, without exciting suspicion on the part of a coronary or medical witness, may be an occasional cause of death in infants. In order to quiet a child, and to enable a nurse to sleep without disturbance, a bag made of wash-leather or rag, containing sugar, is thrust into the child's mouth. It is thus completely gagged, and the child soon becomes quiet, respiring chiefly through the nostrils. If these by any accident become obstructed, or by the act of respiration the bag should fall to the back of the fauces, death by suffocation must inevitably result,—the infant being perfectly helpless! The suspension of respiration may be so gradual that the child may die without crying or convulsions. The removal of the bag from the mouth will remove every trace of the cause of death; for no pressure is exerted; and in order to exculpate herself, the guilty person may
DEATH FROM SMOOTHERING.

Ascribe death to "fits." In one instance, within my knowledge, an infant was timely saved by the mother having discovered, while the nurse was sleeping, a mass of wash-leather projecting from the mouth of the child. The woman awoke, and attempted to remove and conceal it; but was detected. The detection of this abominable practice can only be a matter of pure accident: hence, a fatal case can be rarely the subject of a coroner's inquest, and even then medical evidence may fail to throw any light upon the cause of death. In one instance only have I known it to give rise to a criminal charge. (In re v. Cox, Warwick Lent Assizes, 1848.) The mother, a pauper female, was tried for the attempt to suffocate her infant eleven days old. The child was discovered by another person with a piece of rag hanging from its mouth. It was livid in the face, but when the rag was removed it made a violent gasp, and recovered its breath. There was no malice on the part of the prisoner, but it was made a strong point in her favour that instances had occurred in the workhouse, in which women had put rags with sugar into the mouths of infants in order to soothe and keep them quiet! The jury acquitted her. This admitted practice of infantile suffocation in the Warwick workhouse appears to have passed without reprimand or even comment, although this plan of soothing infants is just as likely to be as fatal to them as that of encircling their necks with a ligature.

SMOTHERING.

Smothering is a variety of suffocation, and consists in the mere covering of the mouth and nostrils in any way so as to prevent the free ingress and egress of air. Like drowning, hanging, or strangulation, it produces death by asphyxia. In new-born infants it is not an unusual occurrence, sometimes originating in accident, and at others in criminal design. An infant is very speedily destroyed by smothering. If the mouth be only lightly covered over with clothing, or slightly compressed, so that respiration is interrupted, as in the act of carrying a child in the arms, this will suffice to cause death: and, as it has been already remarked, death often takes place without being preceded by convulsions or other striking symptoms. Smothering is not often resorted to as a means of perpetrating murder, except in infants, or in debilitated and infirm adults. In a case which occurred at Ayr, a woman was charged with the murder of her child by smothering it in her shawl. She was travelling in a steam-boat: it was a cold stormy day, and she had wrapped the shawl closely round the head of the child. There could be no doubt from the moral circumstances that she had intended to kill it; but the defence was that she had merely intended to protect the child from the cold, and it was suffocated before she was aware of it. There
were no facts to exclude this defence, and the woman was acquitted. I have known an instance in this metropolis, in which an infant was unintentionally destroyed by the close wrapping of a shawl round its head. In December, 1852, Mr. Thornley, of Blyth, Nottinghamshire, consulted me in a case in which an infant was found dead in bed. It was a perfectly healthy child, about three months old. It had been left by the nurse in bed quite well at 6.30 in the morning, when she got up. Soon afterwards the father went into the room and could not see the child: but on removing the bed-clothes, it was found beneath them, quite dead, its head covered completely by six folds of clothes. In a quarter of an hour after it had been left by the servant, Mr. Thornley saw the child: it was dead. The body was quite warm (showing recent death), the countenance was calm, the limbs were relaxed: there was a little frothy mucus about the mouth, but nothing to indicate a violent death. There was no doubt, from the circumstances, that the child had been accidentally smothered or suffocated: its body had slipped down beneath the clothes—the mouth and nostrils were covered, and asphyxia speedily came on, which proved fatal owing to the helplessness of the infant.

Certain trials which took place some years since, clearly proved that individuals, in a state of intoxication or infirmity, had been murdered by smothering, for the sake of the money derived from the sale of the dead bodies! It will be sufficient to mention the trials of Burke and Macdowall in Edinburgh, and of Bishop and Williams in this metropolis, as affording ample evidence of the past existence of this horrible system of secret murder. (See Ed. Med. and Surg. Jour. April 1829, p. 236.) The victims were commonly destroyed by the murderer resting with his whole weight upon the chest, so as to prevent the motion of the ribs, and at the same time forcibly compressing the mouth and nostrils by his hands, to prevent the ingress of air. A case of this kind was referred to me for examination in 1831. (Rex v. Elizabeth Ross, Old Bailey S. Dec. 1831.) It was remarkable for the fact that the prisoner was convicted of homicidal suffocation, although the body of the deceased was never discovered. (See Med. Gaz. xxxvii. 481.) In Nov. 1844, a man was convicted at the Assizes of the Scire of the murder of a woman by placing a pitch-plaster over her face. A trial for murder by smothering took place at the Lincoln Lent Assizes, 1843. (The Queen v. Johnson.) The prisoner, while committing a burglary, tied the deceased to a bed, so that she could not move, and then closely tucked the clothes over her head. After remaining some hours in this condition, the deceased died. The prisoner was convicted and executed. For an important case, involving the question of death from homicidal smothering, or from apoplexy, see that of the Queen v. Heywood, Lancaster Summer
POISONING BY GASES AND VAPOURS.

Ass. 1839. As an accident, smothering may be conceived to take place when a person falls in a state of intoxication and debility, so that his mouth is in any way covered, or the access of air to the mouth or nostrils is interrupted. On an inspection of the body, the appearances described under the head of asphyxia will be met with in the organs of circulation and respiration; hence in a suspected case of murder, we must look for the common indications of asphyxia (ante, p. 736), and to the circumstances under which the body is found, before we can offer an opinion on the probable cause of death. (For some additional facts connected with this subject, see Ann. d'Hyg. 1837, ii. 485.)

CHAPTER LXII.

Mode of action of gaseous poisons.—In following common language, a medical jurist is obliged to apply the term suffocation to another variety of death; viz. to that of poisoning by gaseous. Physiological accuracy must here be sacrificed, in order that we may make ourselves generally intelligible. Thus, if a person die from the effect of carbonic acid,—of confined air,—of sulphured hydrogen, or other noxious gases, he is commonly said to die suffocated. Strictly speaking, he dies poisoned; as much so as if he had taken oxalic or hydrocyanic acid. The only differences are,—1. That the poison, instead of being liquid or solid, is gaseous: and—2. Instead of being applied to the mucous membrane of the stomach, it affects that of the air-cells of the lungs. In the case of arsenured hydrogen (ante, p. 96), we have a clear instance of poisoning by gas; and in the respiration of the narcotic vapours of chloroform and ether, we have also illustrations of this form of poisoning. Owing to the fact that the poisonous material is in a finely divided state, and that in the air-cells of the lungs it meets with a large absorbing surface, and instantly enters the blood, the effect is more rapid, and ceteris paribus, more powerful. It has been remarked, too, that some, and probably all these aerial poisons, have an accumulative action; i.e. their effect continues to increase for a short period, even after the individual has ceased to respire them.
GASEOUS POISONING. CAUSE OF DEATH MISLAKEN.

The cause of death mistaken.—The greater number of the poisonous gases are chiefly complex products of art, and are never likely to be met with in the atmosphere so abundantly as to produce injurious consequences:—hence fatal accidents, arising from their inhalation, most commonly occur under circumstances which can leave no question respecting the real cause of death. The peculiar effects of all of these it will not be necessary to describe in this place; but there are two, a knowledge of the properties and operations of which may, on certain occasions, be required of a medical jurist:—these are, the CARBONIO ACID and SULPHURETTED HYDROGEN GASES. Agents of this description can rarely be employed with any certainty as instruments of murder; and if they were so employed, the fact could be established only by circumstantial evidence. One alleged instance of murder by carbonic acid is, however, reported by M. Devergie. (Ann. d’Hyg. 1837, i. 201.) Death, when arising from the respiration of any of the gases, is generally attributable to suicide or accident. In France it is by no means uncommon for individuals to commit self-destruction by sleeping in a closed apartment, in which charcoal has been suffered to burn; while in England accidental deaths are sometimes heard of, where coal has been employed as fuel in small and ill-ventilated rooms. On such occasions a person may be found dead without any apparent cause to the casual observer,—the face may appear tumid and discoloured, and the cutaneous surface may be covered with ecchymosed patches. The discovery of a body under these circumstances, will commonly be sufficient, in the eyes of the vulgar, to create a suspicion of murder; and some person, with whom the deceased may have been at that period on bad terms, will, perhaps, be pointed out as the murderer. In such a case, it is obvious that the establishment of the innocence of an accused party may depend entirely on the discrimination and judgment of a medical practitioner. An instance, illustrative of the consequences of this popular prejudice, occurred in London in 1823. Six persons were lodging in the same apartment, where they were all in the habit of sleeping. One morning an alarm was given by one of them, a female, who stated that on rising she found her companions dead. Four were discovered to be really dead, but the fifth, a married man, whose wife was one of the victims, was recovering. He was known to have been on intimate terms with the female who gave the alarm, and it was immediately supposed that they had conspired together to destroy the whole party, in order to get rid of the wife. The woman who was accused of the crime was imprisoned; and an account of the supposed barbarous murder was soon printed and circulated in the metropolis. Many articles of food about the house were analysed, in order to discover whether they contained poison, when the whole of the circumstances were explained by the man
POISONING BY CARBONIC ACID.

stating that he had placed a pan of burning coals between the two beds before going to sleep, and that the doors and windows of the apartment were closed. (Christison, 583.) A set of cases of a similar kind, in which there was at first a very strong suspicion of poisoning, has been reported in the Medical Gazette, by Mr. Smith, of Liverpool (vol. xxxvi. p. 937).

CARBONIC ACID.

Symptoms.—The symptoms of poisoning by this gas will vary according to the degree of concentration in which it is present in the atmosphere respired. When it exists in a fatal proportion, the symptoms commonly observed are as follows:—A sensation of great weight in the head, giddiness, a sense of constriction in the temporal regions, a ringing in the ears with a pungent sensation in the nose; a strong tendency to sleep, accompanied by vertigo, and so great a loss of muscular power, that, if the individual be at the time in an erect posture, he instantly falls as if struck to the ground. The respiration, which is observed to be at first difficult and stertorous (snoring), becomes suspended. The action of the heart, which on the first accession of the symptoms is very violent, soon ceases. Sensibility is lost, and the person now falls into a profound coma, or state of apparent death. The warmth of the body still continues; the limbs remain flexible, but they have been observed to become rigid or even occasionally convulsed. The countenance is commonly of a livid or of a deep leaden colour, especially the eyelids and lips, but on some occasions it is stated to have been pale. The access of these symptoms is stated to have been sometimes accompanied by a pleasing sensation of delirium, while at others the most acute pains have been suffered. In some instances there appears to have been irritability of the stomach; for the affected person has vomited the contents of the stomach in a semi-digested state. Those who have been resuscitated have often felt pain in the head, or pain and soreness over the body, for several days; while, in a few severe cases, paralysis of the muscles of the face has supervened on recovery.

Appearances after death.—Externally, the whole of the body appears as if it were swollen, especially the face, which is generally livid, and the features are much distorted. The cutaneous surface is covered in parts by patches of a violet hue, but, in some instances, the skin has been extremely pale; the eyes are generally prominent, and, in many cases, retain their usual brilliancy some time after death. The body of a person who has perished from the inhalation of carbonic acid is said to retain the animal heat, ceteris paribus, for a longer period than usual; and hence, according to Orfila, cadaveric rigidity does not commonly manifest itself until after the lapse of many hours. In a case to be related presently, the body was, however, found to have

3 H
cooled considerably within the short space of two hours. On
inspection, the venous system is found filled with blood of
a dark colour; and the vessels of the lungs and brain are ob-
served to be especially in a state of congestion. The tongue
appears swollen, and it is stated by Orfila that the mucous mem-
brane of the intestinal canal is often interspersed with dark
eechymosed patches. The following appearances were met with
thirty hours after death in the bodies of two adults, male and fe-
male, who died from the accidental introduction of carbonic acid
from burning ashes into their bed-room. Externally there was
nothing unnatural, excepting a few slight discolorations on the back
of the man. Internally there was congestion of the membranes
and great vessels of the brain. Each lateral ventricle contained
about half an ounce of clear serum. The lungs were gorged with
dark blood: and the lining membrane of the air-tubes (bronchi)
was slightly reddened. The left sides of the hearts were nearly
empty: the right contained a quantity of dark half-coagulated
blood. The stomachs were healthy. The bodies were found on
the floor of the bed-room in easy positions. The deceased had
had the power to get out of bed, but were unable to escape from
the chamber. It will be perceived from this description that
there is nothing very characteristic in the appearances, and that
it is always easy to ascribe death to apoplexy or some other
cause; but it should be remembered that carbonic acid itself
acts by inducing apoplexy or cerebral congestion.

The following case of death from carbonic acid was com-
municated to me by Mr. Procter, of York. The deceased, an
old woman, occupied a room under one in which there was a
quantity of nitric acid kept in store. Owing to some accident a
barbey was broken—the acid ran through the ceiling into the room
below, acting upon and corroding the bed-coverings of the
deceased's bed. As the room was quite filled with the nitric acid
fumes, a chemist was consulted, and he advised that whiting should
be freely used for the purpose of neutralising the acid. This advice
was followed, and several persons who were in the room witnessing
the operation, felt oppressed and were obliged to leave it.
They were observed to stagger, as if intoxicated, on reaching the
street. The room was then completely closed, and the whiting
allowed to remain in contact with the acid. The deceased had
suffered from diarrhoea for a few days previously, and was obliged
to resort to the night-chair, which was in the room in which the
accident had occurred. As she remained absent half an hour
some persons entered the apartment and found her in the chair
unable to move. She was taken into another room, and on a
medical man being called to her, he found her sleepy and coma-
tose—her mind confused,—there was great difficulty of breathing,
—extreme lividity of the face and lips,—the arms and legs were
cold, and the pulse was full. In spite of efforts made to save
CARBONIC ACID. ANALYSIS. 835

her, she died in about an hour from the time at which she entered the room. Those who found her in the apartment do not appear to have suffered. This was a case of slow poisoning by carbonic acid, for no carbonic oxide could have been evolved from the action of the acid in the chalk. Age, and debility from previous illness, may account for the unusual circumstance that the deceased did not recover on being removed to a pure atmosphere.

Analysis.—Sometimes a medical jurist may be required to state, for the purposes of justice, the nature of the gaseous mixture in which a person may have died. He will have but little difficulty in determining whether carbonic acid be the deleterious agent in such a mixture. When it exists in a confined atmosphere, its presence may be identified, if previously collected in a proper vessel, by the following characters. 1. It extinguishes a taper if the proportion be above twelve or fifteen per cent; and, from the extreme density of the gas, the smoke of the extinguished taper may be commonly seen to float on its surface. 2. Lime-water, or a solution of subacetate of lead, is instantly precipitated white when poured into a jar of the gas; and the precipitate thus formed may be collected by filtration, and proved to possess the well-known properties of carbonate of lime or lead. Air containing only one per cent of carbonic acid scarcely affects lime-water. The proportion in which carbonic acid exists in a mixture, may be determined by introducing into a measured quantity, in a graduated tube over mercury, a strong solution of caustic potash. Absorption will take place after a certain time, and the degree of absorption will indicate the proportion of carbonic acid present. When this destructive agent exists in a confined spot, as in a well or cellar, it may be generally got rid of by placing within the stratum a pan containing the hydrate of lime, loosely mixed into a paste with water; by exciting combustion at the mouth of the pit; or what is better, when available, by a jet of high-pressure steam. Lives are often successively lost on these occasions in consequence of one person descending after another, in the foolish expectation of at least being able to attach a rope to the body of his companion. The moment that the mouth comes within the level of the stratum, all power is lost, and the person commonly sinks lifeless. The gas may be collected by lowering a bottle filled with fine sand by means of a string attached to the neck, and guiding the bottle by another string attached to its base. When the bottle is within the stratum, it should be turned with its mouth downwards; and, when the sand has fallen out, it may be rapidly raised with its mouth upwards, by pulling the string attached to the neck.
EFFECTS OF CHARCOAL-VAPOUR.

CHARCOAL-VAPOUR.

Products of burning charcoal.—The gas extricated during the combustion of charcoal, according to the experiments of Orfila, is not pure carbonic acid, but a very compound mixture. It operates fatally when respired, chiefly in consequence of the carbonic acid contained in it: the proportion of this gas is, however, subject to variation.

Symptoms and appearances after death.—The following case, illustrating the effects of charcoal vapour, has been reported by Mr. Collambell. (Med. Gaz. xxvii. 693.) In January 1841, a man was engaged to clean the windows of three small rooms on the basement-story of a house. The first room had a door opening into a courtyard, the others merely communicated with each other by a central door, and there was no fireplace in any one. A brazier of burning charcoal had been placed in the outer room for the purpose of drying it, but it appeared that the deceased had shut the outer door, and had removed the brazier into the inner room of the three, leaving the communicating doors open. In two hours the man was found quite dead, lying on the floor of the middle room. The countenance was pale, as well as the whole of the skin; the eyes were bright and staring, the pupils widely dilated; the lips bloodless; the jaw firmly fixed; the tongue protruding; and the face and limbs were cold. Some frothy mucus had escaped from the mouth. The person who discovered the deceased found the ashes in the brazier still burning, and he experienced great oppression in breathing. An inquest was held without an inspection, and a verdict of accidental death returned. The body was afterwards privately inspected by Mr. Collambell. On opening the head, the vessels on the surface of the brain were found highly distended with dark liquid blood; the pia mater was bedewed with serum. The brain was of unusually firm consistency, and numerous bloody points appeared on making a section of it. The lateral ventricles were distended with about an ounce and a half of pale serum, and the vessels of the plexus choroides were much congested. The cerebellum was firm, and presented on section numerous bloody points. About two ounces of serum, tinged with blood, were collected from the base of the skull. The lungs had a slate colour. On the left side of the chest there were eight ounces of serum, tinged with blood, and nearly an equal quantity on the right side. On cutting into the organs, a large quantity of serous fluid, mixed with blood, escaped. The bronchial tubes were filled with a frothy fluid tinged with blood. The pericardium contained an ounce of pale serum; the heart was enlarged; the cavities contained no blood; the liver and kidneys were, however, much gorged. There was no doubt that the cause of death was the inhalation of charcoal-vapour; and it is probable that the man died from respiring but a comparatively
small proportion. The capacity of the chambers must have nearly reached two thousand cubic feet; the deceased had been there only two hours, and, when the person who discovered him entered the rooms, the air was not so vitiated but that he could breathe, although with some oppression. The fuel was then in a state of combustion. In a case which was referred to me for examination in 1851, there was a considerable effusion of blood in the submucous tissue of the stomach. This appearance led to a strong suspicion of irritant poisoning. A full investigation of the circumstances, however, showed that the suspicion was unfounded. Carbonic acid had descended through a flue communicating with the bed-room in which deceased slept with her husband; it destroyed the wife, and nearly killed the husband. A stove with burning charcoal had been placed in the room above that in which the couple slept, and an iron pipe conveyed the products of combustion into a flue whence they descended into the bed-room and caused the fatal accident. In one fatal case there was copious bleeding from the nose. (Med. Gaz. xlvii. p. 412.)

Power of locomotion.—It often excites surprise on these occasions that no exertion is made to escape, when it would apparently require but very slight efforts on the part of the individual. The fact is, that the action of the vapour is sometimes very insidious; one of its first effects is to create an utter prostration of strength, so that even on a person awake and active, as in the case above related, the gas may speedily produce a perfect inability to move or to call for assistance. For some remarks on the action of charcoal-vapour by Dr. Bird, see Guy's Hospital Reports, April 1839; and for a case illustrative of the dangerous effects of the diluted vapour, see Ed. Med. and Surg. Journ. i. 541. In this instance, a charcoal brazier was left only for a short time in the cell of a prison. It was removed, and the prisoners went to sleep. They experienced no particular effects at first, but after some hours, two were found dead. Thus, then, an atmosphere which may be breathed for a short time with impunity, may ultimately destroy life.

COAL- AND COKE-VAPOUR. SULPHUROUS ACID.

Products from burning coal and coke.—The gases extricated in the smothered combustion of coal or coke are of a compound nature. In addition to carbonic acid, we may expect to find in the atmosphere of a close room, in which such a combustion has been going on, sulphurous acid gas, and from coal, in addition to this, the sulphuretted and carburetted hydrogen gases. These emanations are equally fatal to life; but in consequence of their very irritating properties, they give warning of their presence, and are therefore less liable to occasion fatal accidents. From an
Death from Coal-Vapour.

Accident which occurred at Colchester a few years since, in which two children lost their lives, it would appear that some persons are so ignorant as to believe that the vapour of coke is less fatal than the vapour of charcoal. The sulphurous acid gas, when existing in a very small proportion in air, has the effect of irritating the air-passage so violently, that, if accidentally respired, it would commonly compel the individual to leave the spot before the vapors had become sufficiently concentrated to destroy life. Nevertheless, accidents from the combustion of coal and coke sometimes occur.

Symptoms and appearances.—The following cases will convey a knowledge of the symptoms and appearances which are commonly met with on these occasions. Some years since, four persons, in a state of asphyxia, were brought to Guy's Hospital. It appeared that on the previous evening they had shut themselves up in the forecastle of a coal-brig, and had made a fire. About six or seven o'clock on the same evening, some of the crew accidentally placed a covering over the flue on the outside, and thus stopped the escape of smoke from the fire, which was made of a kind of coal containing much sulphur. Early in the morning, one of the crew, on opening the hatches, observed three of the inmates lying on the floor senseless and frothing at the mouth; the fourth in his crib, in a similar condition. The air in the place was most offensive. After the men were brought on deck, one of them, aged twenty-one, began to recover; and, when brought to the hospital, he seemed only giddy, as if intoxicated. He soon completely recovered. Another, aged forty, after breathing oxygen gas and having brandy and ammonia exhibited to him, showed no symptoms of recovery, but died in a few hours. A third, aged seventeen, soon began to rally, and in a few hours was perfectly enabled to answer questions; he declared that he felt no pain, sense of oppression, weight, either in his head or chest. The fourth, aged fifteen, died the following day, having exhibited no symptom of rallying. Stimulants were administered internally, and warm fomentations were used, but all efforts to produce reaction failed. The appearance of these persons, when brought in, was as follows:—lips purple, countenance livid, surface of the body cold, hands and nails purple, respiration very quick and short; pulse small, quick, and feeble; pupils fixed, and there was total insensibility. The body of the man aged forty was inspected four hours after death. The membranes of the brain were congested, and there was a large quantity of fluid under the tunica arachnoides. The sinuses were gorged with blood. The lungs were in a state of great congestion, as also the right cavities of the heart. It was remarked, that this corpse was similar in appearance to that of an executed culprit. The body of the lad aged fifteen was inspected about thirty-three hours after death. Under the pia mater was observed one small ecchymosed spot;
VAPOUR OF LIME- AND BRICK-KILNS.

in the substance of the brain there were more bloody points than usual; a small quantity of fluid was found under the tunica arachnioides, and the sinuses were full of coagulated blood. The lungs showed no congestion, but the right cavities of the heart were much distended with blood. (For an account of two cases of recovery from the effects of coal-vapour, see Med. Gaz. ix. 935: also, Dub. Med. Press, Jan. 31, 1849, p. 69, and Med. Gaz. xliii, p. 937.)

A case showing the fatal effects of coal-vapour has been published by Dr. Davidson. The man lost his life from sleeping in a crowded room with a fire to which there was no flue. The lungs were found gorged with blood, and the trachea and bronchi were filled with a frothy muco-sanguineous fluid; the mucous membrane beneath was slightly injected. There was a small effusion in each pleural cavity. The right side of the heart was full of dark liquid blood. The dura mater was much injected; the sinuses of the brain and the veins of the pia mater were completely congested, and there was sub-arachnoid effusion. The substance of the brain, when cut, presented numerous bloody points. (Month. Jour. April 1847, 763.) In the Medical Times and Gazette (April 3, 1852, p. 353) the reader will find an account of three cases of recovery from the effects of coal-vapour.

Analysis.—Sulphurous acid is immediately known by its powerful and suffocating odour, which resembles that of burning sulphur. The best test for its presence is a mixture of iodic acid and starch, which speedily acquires a blue colour when exposed to the vapour.

VAPOUR OF LIME- AND BRICK-KILNS.

Gaseous products from lime-burning.—In the burning of lime, carbonic acid is given out very abundantly and in a pure form. It has been owing to the respiration of the gas thus extricated, that persons who have incautiously slept in the neighbourhood of a burning lime-kiln during a winter's night have been destroyed. The discovery of a dead body in such a situation would commonly suffice to demonstrate the real cause of death; but a practitioner ought not to be the less prepared to show that there existed no other apparent cause of death about the person. It is obvious that a person might be murdered, and the body placed subsequently near a kiln by the murderer, in order to avert suspicion. If there be no external marks of violence, the stomach should be carefully examined for poison; in the absence of all external and internal lesions, medical evidence will avail but little; for a person might be criminally suffocated, and his body, if found under the circumstances above stated, would present no appearances upon which a medical opinion could be securely based. An accident is related by Rodari to have oc-
occurred at Marseilles, in which seven persons of a family were destroyed in consequence of their having slept on the ground-floor of a house, in the courtyard of which a quantity of limestone was being burnt into lime. They had evidently become alarmed, and had attempted to escape; for their bodies were found lying in various positions. The courtyard was enclosed, and the carbonic acid had poured into the apartment through the imperfectly closed window and door. In November 1838, a man died three days after being exposed to the vapours of a lime-kiln. (Guy's Hosp. Rep. April 1839.) The vapour of a brick-kiln is equally deleterious, the principal agent being carbonic acid, although I have found that ammonia and muriatic acid are also abundantly evolved. In September 1842, two boys were found dead on a brick-kiln near London, whether they had gone for the purpose of roasting potatoes. Although the cause of death in the two cases was clearly suffocation, in one instance the body was extremely livid, while in the other there was no lividity whatever! Such accidents are very frequent. In November 1844, an inquest was held at Manchester on the body of a man who had died under similar circumstances.

CONFINED AIR.

Symptoms and effects.—An animal confined within a certain quantity of air which it is compelled to respire, will soon fall into a state of lifelessness. A human being in the same way may be suffocated, if confined in a close apartment where the air is not subject to change or renewal, and this effect is hastened when a number of persons are crowded together in a small space. The change which air, thus contaminated by respiration, undergoes, may be very simply stated. The quantity of nitrogen in a hundred parts will remain nearly the same; the quantity of oxygen will probably vary from eight to twelve per cent, while the remainder will be made up chiefly of carbonic acid. Such air will also have a high temperature if many persons are crowded together, and will be saturated with aqueous vapour containing animal matter poured out by the pulmonary and cutaneous exhalants. From this statement, it is evident that air which has been contaminated by continued respiration will operate fatally on the human system, partly in consequence of its being deficient in oxygen, and partly from the deleterious effects of the carbonic acid contained in it. The proportion in which carbonic acid exists in respired air, is subject to great variation; according to the experiments of Allen and Pepys, it never exceeds ten per cent by volume of the mixture, how frequently soever it may have been received into and expelled from the lungs. Dalton found that the air in crowded rooms contained about one per cent of carbonic acid, the atmospheric proportion being therefore
increased nearly twenty-fold. It is certain that insensibility and
death would ensue in a human adult, before the whole of the
oxygen of the confined air had disappeared; but the opportunity
can rarely present itself of analysing such a contaminated mix-
ture, and hence it is impossible to specify the exact proportion
in which carbonic acid would exist, when the confined air had
proved fatal to persons who had respired it. M. Lassaigne has
shown by direct experiment, that the carbonic acid in the air of
close rooms is not collected on the floor, but equally diffused
throughout. The whole mass of air is in fact vitiated, and re-
quires renewal. (Med. Gaz. xxxviii. 351.)

COAL-GAS. CARBURETTED HYDROGEN. CARBONIC OXIDE.

Since the introduction of coal-gas for the purposes of illumina-
tion, many fatal accidents have occurred from the respiration of
air contaminated with it. Coal-gas is a compound body, acting
as a direct poison when respired. Its composition is subject to
much variation, according to circumstances. Mitscherlich found
that it was principally composed of light carburetted hydrogen,
hydrogen, and carbonic oxide, in the proportions of 66 per cent
of the first, 21 of the second, and 11 of the third. M. Tourdes
found that the proportions of light carburetted hydrogen and
carbonic oxide were nearly equal, i.e. about 22 per cent. The
difference in composition depends on the heat to which the gas
has been submitted. Some consider that carbonic oxide is the
poisonous principle; but there is no doubt that the hydrocarbons
also have a noxious influence, although the use of the safety-lamp
in mines proves that a mixture of light carburetted hydrogen with
air in a small proportion may be respired without producing
serious effects.

Symptoms and appearances after death.—The symptoms pro-
duced by coal-gas, when mixed in a large proportion with air, are,
giddiness, headache, nausea with vomiting, confusion of intel-
lect with loss of consciousness, general weakness and depres-
sion, partial paralysis, convulsions, and the usual phenomena of
asphyxia. The appearances after death will be understood from
the following cases. In January 1841, a family residing at
Strasburg respired for forty hours an atmosphere contaminated
with coal-gas which had escaped from a pipe passing near the
cellar of the house in which they lodged. On the discovery of
the accident, four of the family were found dead. The father
and mother still breathed; but, in spite of treatment, the father
died in twenty-four hours: the mother recovered. On an in-
spection of the five bodies there was a great difference in the
appearances; but the principal points observed were, congestion
of the brain and its membranes, the pia mater gorged with blood,
and the whole surface of the brain intensely red. In three of
the cases there was an effusion of coagulated blood on the interior of the spinal canal. The lining membrane of the passages was strongly injected, and there was spread over a thick viscid froth tinged with blood; the substance of the brain was of a bright red colour, and the blood was coagulated. (Ann. d’Hyg., Jan. 1842.) In two cases communicated by Mr. T. to the Guy’s Hospital Reports (No. viii.), there was found a dissection of the brain and its membranes, with injection of the lining membrane of the air-passages. In these cases the air was remarkably liquid. The circumstances under which the accident occurred were very similar. An aged female and her grand-daughter, who had been annoyed by the escape of gas during the day, retired to bed, and were found dead about six hours afterwards.

In the cases above given, the effects produced by coal-gas were owing to the long-continued respiration of it in a diluted state. The quantity contained in the air of the rooms must have been very small; in M. Tourdes’ case it was probably not more than 8 or 9 per cent., because at a little above this proportion the mixture with air becomes explosive, and there had been no escape in this case, although in the apartment in which the individuals were found dead, a stove had been for a long time in active condition, and a candle had been completely burnt out. In Mr. T.’s case, those who entered the house perceived a strong smell of coal-gas; but still the air could be breathed. Coal-gas, like other aerial poisons, may destroy life if long respired, although so diluted as not to produce any serious effects in the first instance! This gas owes its peculiar odour to the vapour of naphtha; the odour begins to be perceptible in air when the forms only the 1000th part; it is easily perceived when forms the 700th part, but the odour is well marked when it forms the 150th part (Tourdes). In most houses in which gas is burnt, odour is plainly perceived; and it is a serious question whether health and life may not often be affected by the long-continued respiration of an atmosphere containing such a small proportion of the gas. The odour will always convey a sufficient warning against the poisonous effects. It should be known that this gas will penetrate into dwellings in a very insidious manner. In Mr. T.’s cases, the pipe from which the gas had escaped was six feet from the wall of the bed-room where the female slept. The gas had permeated through the loose earth and bricks, and entered the apartment through the floor! It is possible to determine exactly what proportion of this gas is in the air. An atmosphere containing from 7 to 12 cent has been found to destroy dogs and rabbits in a few minutes when the proportion was from 1 1/2 to 2 per cent., it had little effect. With respect to man, it may destroy life if respired when forming about 9 per cent, i.e., when it is in
than an explosive proportion. (See B. and F. Med. Rev. xxix. 253; also, Ann. d’Hyg. 1830, i. 457.)

M. Tourdes has ascertained that rabbits died in twenty-three minutes, when kept in an atmosphere containing 1-15th of its bulk of pure carbonic oxide. When the proportion was 1-30th, they died in thirty-seven minutes, and when 1-8th, in seven minutes. The action of the gas on the body is that of a pure narcotic: it appears to be a powerful poison.

Analysis.—The circumstances under which the accident occurs will generally suffice to establish the nature of the gas. Coal-gas burns with a bright white light, producing carbonic acid and water. A taper should be cautiously applied to a small quantity; since, when the gas is mixed with air in the proportion of from 11 to 14 per cent, it is dangerously explosive. For this reason no lighted candle should be taken into an apartment where an accident has occurred, until all the doors and windows have been for some time kept open. (See Med. Gaz. vol. xlii. p. 843.) The combustion of the gas, or its explosion with air, is a sufficient test of its nature; the peculiar odour, and the want of action on a salt of lead, will distinguish it from sulphuretted hydrogen.

Carbonic oxide is known by the fact that when kindled it burns with a pale blue light, and produces carbonic acid and water by its combustion.

CHAPTER LXIII.

SULPHURETTED HYDROGEN GAS—SYMPTOMS—APPEARANCES.—
EFFLUVIA OF DRAINS AND SEwers—ANALYSIS.—EXHALATIONS
OF THE DEAD.

Sulphuretted Hydrogen. Symptoms.—The symptoms produced by sulphuretted hydrogen on the human system vary according to the degree of concentration in which it is respired. When breathed in a moderately diluted state, the person specically falls inanimate. An immediate removal to pure air, venesection, and the application of stimulants, with cold affusion, may, however, suffice to restore life. According to the account given by those who have recovered, this state of inanition is preceded by a sense of weight in the stomach and in the region of the temples; also by giddiness, nausea, sudden weakness, and loss of motion and sensation. If the gas in a stillless concentrated state can be respired for some time, coma (insensibility), or tetanus with delirium, supervenes, preceded by convulsions or pain and weakness over the whole of the body. The skin in such cases is commonly cold, the pulse irregular, and the respiration laborious. When the air is but slightly contaminated by the gas, it is
for a longer time without producing any serious symptoms; there is a feeling of nausea, or sickness, with loss of appetite, great bodily weakness, accompanied by pain in the head, or diffused pains in the abdomen. These symptoms occasionally affect those who are engaged in chemical manipulations with this gas.

In all cases a noxious atmosphere containing this gas is indicated by a foul smell producing nausea or sickness. The following may be taken as a good example of the effects of slow poisoning by the diluted gas. The men who were engaged in working at the Thames Tunnel suffered severely during the excavation, from the presence of this gas in the atmosphere in which they were obliged to work. The case was referred to me for examination by Sir I. M. Brunel, in 1839. The air, as well as the water which trickled through the roof, was found to contain sulphuretted hydrogen: it was probably derived from the action of the water on the iron-pyrites in the clay. The gas issued in sudden bursts, so as to be at times perceptible by its odour. By respiring this atmosphere, the strongest and most robust men were, in the course of a few months, reduced to an extreme state of exhaustion, and several died. The symptoms with which they were first affected were giddiness, sickness, and general weakness; they became emaciated and fell into a state of low fever, accompanied by delirium. In one case which I saw, the face of the man was pale, the lips of a violet hue, the eyes sunk, with dark arcoles around them, and the whole muscular system flabby and emaciated. Chloride of lime and other remedies were tried for the purification of the air; but the evil did not entirely cease until the tunnel was so far completed that there was a communication from one side to the other, and free ventilation throughout.

Sulphuretted hydrogen appears to act like a narcotic poison when highly concentrated; but like a narcotico-irritant when much diluted with air. It is absorbed into the blood, to which it gives a brownish-black colour, and it is in this state circulated throughout the body. (The reader will find a case of poisoning by this gas, in which the person recovered, Medical Gazette, vol. xlviii. p. 871.)

Appearances after death.—On examining the bodies of persons who have died from the effects of sulphuretted hydrogen when respired in a concentrated form, and the inspection is recent, the following appearances have been observed. The mucous membrane of the nose and fauces is commonly covered by a brownish viscid fluid. An offensive odour is exhaled from all the cavities and soft parts of the body. These exhalations, if received into the lungs of those engaged in making the inspection, sometimes give rise to nausea and other unpleasant symptoms, and may even cause syncope or asphyxia. The muscles of the body are of a dark colour, and are not susceptible of the galvanic stimulus.
The lungs, liver, and the soft organs generally, are distended with black liquid blood. There is also great congestion about the right side of the heart, and the blood is said to be everywhere dark-coloured and not to become coagulated after death: the body rapidly undergoes the putrefactive process. When death has occurred from the respiration of this gas in a more diluted form, these appearances are less marked. There is then general congestion of the internal organs with a dark and liquid state of the blood. In fact in such cases the appearances can scarcely be distinguished from those produced by carbonic acid.

In June 1857, six persons lost their lives at Cleator Moor, near Whitehaven, by the respiration of this gas in a diluted form, by reason of their having slept in small, close, ill-ventilated rooms,—into which sulphuretted hydrogen had penetrated. Three of the deceased persons, a husband, wife and, child of one family (Armstrong), had retired to rest in their usual health, on the night of the 9th of June. Two of them were found the next morning dead in bed, and a third (the child) was found in a state of insensibility, and lingered until the afternoon of the same day, when she died. The fourth, a healthy adult, retired to sleep in his bed with the door closed, and he was found dead in an hour. The fifth, a child, was taken ill on the morning of the 11th, and died the same day. The sixth was taken ill on the morning of the 10th, and died on the 12th of June.

The symptoms complained of by some who recovered were nausea, sickness, giddiness, and insensibility. On inspection of the body of one child, the pupils were found dilated,—viscid mucus escaped from the nostrils,—there was congestion of the lungs and kidneys, as well as of the membranes of the brain. In the adult, who died in an hour, the pupils were natural,—the jaws firmly clenched, the fingers contracted,—nails blue,—there was great cadaveric lividity, and a quantity of fluid with frothy mucus issued from the nostrils and mouth. The lungs were much congested, and there was a quantity of serum effused in the cavity of the chest,—the heart contained a little fluid blood and was somewhat flaccid. The membrane of the windpipe and gullet was redder than natural. In the windpipe there was frothy mucus. The stomach, and large and small intestines, were highly congested but otherwise healthy. The brain and its membranes were greatly engorged with blood, which, as in the body generally, was very dark and fluid. Mr. J. B. Wilson, who examined the body of the child, drew the conclusion, which was confirmed by the subsequent inquiry, that death had been caused by sulphuretted hydrogen. Dr. Thompson, who examined the body of the man, inferred that some noxious gas or gases had destroyed life. Having been required by the Home Office to investigate the cause of death in these cases, I visited Cleator
on the 22nd of June, and found that the cottages in which the accidents had occurred were built upon a heap of iron-slag, which also abutted on the premises behind. This slag contained among other matters sulphide of iron and sulphide of calcium. A foul smell, compared to that of cinders extinguished by water, had for some time been perceived about the rooms, chiefly at night when the doors and windows were closed; and the day before the occurrence a heavy storm of rain had washed through the slag-heaps and aggravated the effects. The heap of slag was burning in certain parts, and sulphuretted hydrogen was evolved in large quantities at a depth of a few feet below. At this time, i.e. a fortnight after the deaths, on removing the flags in the lower rooms, the slag below was found damp, and sulphuretted hydrogen was still issuing from it. The lead paint in the corners was partly converted to black sulphuret, and this chemical change was found in patches on the chamber door of one room in which two persons had died.

The symptoms so far as they were observed in the living, the appearances in the dead bodies, and the chemical nature of the wet slag beneath the foundation, left no reasonable doubt that during the night, with the doors and windows closed, sulphuretted hydrogen had escaped in sufficient quantity to poison the air and destroy life, and a verdict was returned to that effect. A suggestion was made that carbonic acid might have caused the symptoms and death;—but there was no source of carbonic acid but the breath, and there is, I believe, no instance known of any adult having breathed himself to death in an hour in a room containing six hundred cubic feet of air,—not to mention that persons had slept in similar rooms in the same row of cottages, at a distance from the slag-heaps, without perishing from this cause. It is highly probable that the sulphuretted hydrogen was mixed with other gases and vapours, as it is never found pure except in a chemical laboratory: but it was no doubt here the agent of death.

In these cases, as in poisoning by carbonic acid, an atmosphere which may be breathed for a short time with impunity will ultimately destroy life (ante, pages 834, 836). Sulphuretted hydrogen in a fatal proportion, however diluted or mixed with other vapours, would always be indicated by a disagreeable smell,—although from habit, as well as probably from the effects of the gas on the nervous system, this offensive smell might not be perceived when a person had remained for a short time in the poisoned atmosphere. In the cases of the Halfa, which occurred at Sheffield in 1852, there is reason to believe that the deaths of two persons were caused by the smouldering of ashes in a cesspool. (Association Medical Journal, April 1853, p. 280.) Mr. Haywood considered that carbonic acid was the agent in this case, although it is probable, from the nature of the materials in
which combustion was going on, that other gases and vapours were simultaneously evolved.

*Effluvia of drains and sewers.*—The most common form of accidental poisoning by sulphuretted hydrogen, for it is rare that a case occurs which is not purely accidental, is witnessed among nightmen and others who are engaged in cleaning out drains and sewers, or in the removal of the soil of privies. These accidents are much more frequent in France than in England, the soil being often allowed to collect in such quantities in Paris and other large Continental cities, as to render the removal of it a highly dangerous occupation for the workmen. According to the results of Thénard’s observations, there are two species of compound gases, or mechanical mixtures of gases, which are commonly met with in the exhalations of privies. The first compound consists of a large proportion of atmospheric air holding diffused through it, in the form of vapour, the *hydrosulphuret of ammonia*. The hydrosulphuret is contained abundantly in the water of the soil, and is constantly rising from it in vapour, and diffusing itself in the surrounding atmosphere. It is this vapour which gives the highly unpleasant odour, and causes an increased secretion of tears in those who unguardedly expose themselves to such exhalations. The *symptoms* produced by the respiration of this gaseous mixture, when in a concentrated state, bear a close resemblance to those which result from the action of sulphuretted hydrogen gas. If a person be but slightly affected, he will probably complain of nausea and sickness; his skin will be cold, his respiration free but irregular; the pulse is commonly frequent, and the voluntary muscles, especially those of the chest, are affected by spasmodic twitches. If more seriously affected, he loses all power of sense and motion, the skin becomes cold, the lips and face assume a violet hue, the mouth is covered by a bloody and frothy mucus; the pulse is small, frequent, and irregular; the respiration hurried, laborious, and convulsive; and the limbs and trunk are in a state of general relaxation. If still more severely affected, death may take place immediately; or should the person survive a few hours, in addition to the above symptoms there will be short but violent spasmodic twitchings of the muscles, sometimes even accompanied by opisthotonos. (See Ann. d’Hyg. 1829, ii. 70.) If the person be sensible, he will commonly suffer the most severe pain, and the pulse may become so quick and irregular that it cannot be counted. When the symptoms are of such a formidable nature, it is rare that a recovery takes place. The *appearances* met with on making an examination of the body are similar to those observed in death from sulphuretted hydrogen. The inspection should be made with caution; for a too frequent respiration of the poisonous exhalations may seriously affect the practitioner. The *treatment* is the same as in poisoning by carbonic acid.
A singular accident occurred in this metropolis in August 1847, in which a man lost his life by the evolution of a quantity of sulphuretted hydrogen from a foul drain. It appears that shortly before the accident, a large quantity of oil of vitriol had been poured down the drain communicating with the privy. The deceased entered the yard, and was soon afterwards found on the pavement in a dying state. On inspection of the body the brain was healthy; but the lungs were gorged with blood, which had the offensive odour of sulphuretted hydrogen gas. The medical witness referred death to this gas, and stated that it had been thrown into the drain, that sulphuret of calcium had probably been formed, and that the sulphuretted hydrogen, which had led to the death of the deceased, had been evolved from this by the oil of vitriol. It is more probable, however, that the gas was evolved by the decomposition of the hydrosulphuret of ammonia, which always abounds in such localities.

The following case, which has a close relation to this subject occurred in London in 1831:—Twenty-two boys, living at a boarding-school at Clapham, were seized in the course of three or four hours with alarming symptoms of violent irritation in the stomach and bowels, spasms of the muscles of the arm, and excessive prostration of strength. One child, which had been similarly attacked three days before, died in twenty-five hours; and one among the last attacked died in twenty-three hours. Both of the bodies were examined after death; in the first, the mucous glands of the intestines were found enlarged, and, as it were, tuberculated. In the second, the mucous coat of the small intestines was found ulcerated, and that of the colon softened. At first it was suspected that the boys had been poisoned, but an analysis of the food did not lead to the discovery of any noxious substance. The only circumstance which was considered sufficient to explain the accident was, that two days before the first child was seized a foul cesspool had been opened, and the materials diffused over a garden adjoining the children’s play-ground. This was the opinion expressed by six medical practitioners.

(Christison on Poisons, 810.)

Analysis.—The recognition of these gases and vapours is a very simple operation. The odour which they possess is sufficient to determine their presence, even when they are diluted with a large quantity of atmospheric air. The sulphuretted hydrogen gas is at once identified by its action on paper previously dipped in a solution of a salt of lead: if present, even in a very small proportion, the moistened paper speedily acquires a brownish-black stain from sulphuret of lead. It must not be supposed that sulphuretted hydrogen, when it has proved fatal in a diluted form, can be detected in the lungs, stomach, or blood of a dead body. When the body is recently removed from a drain or sewer, it may be found pervading the whole of the tissues; but in other cases it will be as useless to look for it, as for carbonic acid, in a case of poi-
SONING BY THIS GAS. Noxious gases are not long retained by the tissues; a short exposure will suffice to remove all traces of the poison. The examination of the locality may throw a light upon the cause. The proportion of the gas found in an apartment can, however, rarely be a criterion of the quantity which has destroyed life. A person going into a room where the deceased bodies are lying, may notice only a disagreeable or a stifling smell, but he may be able to breathe for a longer or shorter period with the door or window open. It is not the respiration of a few minutes, but the breathing of the noxious atmosphere for many hours, that really destroys life. The best method of detecting sulphuretted hydrogen when present in a dead body (not putrefied) is to place a piece of polished silver, or of glazed card, in an incision made into the muscles or soft organs. It will be tarnished, or acquire a brown colour, if the gas be present.

Sulphuretted hydrogen may be proved to exist: by the lead test in the vapour of hydrosulphuret of ammonia when mixed with air; and the presence of ammonia is indicated in the compound by the volatile alkaline reaction on test-paper; also by holding, in a vessel containing the vapour recently collected, a rod dipped in strong muriatic acid: the production of dense white fumes announces the formation of muriate of ammonia. It is a fact which cannot be too universally known, that a candle will readily burn in a mixture of either of these gases with air, which, if respired, would suffice to destroy life. (Ann. d’Hyg. 1829, ii. 69.) It is also worthy of remark, that the air of a cesspool may be often respired with safety until the workmen commence removing the soil, when a large quantity of mephitic vapour may suddenly escape, which will lead to the immediate suffocation of all present. Several persons have been killed by trusting to the burning of a candle, in ignorance of this fact. In descending in order to render assistance to persons who are lifeless, the person should on these occasions, whether sulphuretted hydrogen or carbonic acid be the cause, make a moderate inspiration of pure air and hold his breath while in the noxious mixture. In an accident which occurred in Whitechapel, in August 1857, three men died speedily from breathing the vapour of an old sewer, and two others nearly lost their lives in attempting to assist them. The best plan for getting rid of the gas is by a free exposure of the locality, or by exciting active combustion in it. According to Parent-Duchâtele, men can work in an atmosphere containing from two to three per cent of sulphuretted hydrogen. The air of one of the principal sewers of Paris gave the following results, on analysis, in 100 parts:—oxygen, 13·79; nitrogen, 81·21; carbonic acid 2·01; sulphuretted hydrogen, 2·99.

EXHALATIONS FROM THE DEAD.

It may be proper in this place to make a few remarks on the alleged danger of the exhalations given off by dead bodies in a
state of putrescence. Formerly there existed a groundless fear relative to the examination of a putrefied dead body; and during the last century, on several important occasions, medical witnesses refused to examine the bodies of deceased persons who were presumed to have been murdered, alleging that it was an occupation which might be attended with serious consequences to themselves. Orfila has collected many accounts of the fatal effects which are recorded to have followed the removal of the dead some time after interment. (Traité des Exhumations, vol. i. p. 2, et seq.) He allows, however, that the details of most of these cases are exaggerated, and attributes to other causes the effects which followed. Indeed, the observations of Thouret and Fourcroy prove that these dangers are restricted within a very narrow compass, and that in general, with common precautions, the dead may be disinterred and transported from one locality to another, without any risk to those engaged in carrying on the exhumations. About the latter part of the last century, from fifteen to twenty thousand bodies, in almost every stage of putrefaction, were removed from the Cimetière des Innocens in Paris; and the accidents that occurred during the operations, which lasted ten months, were comparatively speaking few. The workmen acknowledged to Fourcroy, that it was only in removing the recently interred corpses, and those which were not far advanced in decomposition, that they incurred any danger. In these cases, the abdomen appeared to be much distended with gaseous matter; if ruptured, the rupture commonly took place about the navel, and there issued a bloody fetid liquid, accompanied by the evolution of a mephitic vapour,—probably a mixture of carbonic acid and sulphuretted hydrogen. Those who respired this vapour at the moment of its extrication, fell instantly into a state of asphyxia, and died; while others, who were at a distance, and who consequently respired it in a diluted state, were affected with nausea, vertigo, or syncope, lasting for some hours, and followed by weakness and trembling of the limbs. Chloride of lime was formerly employed for decomposing these vapours; but a strong solution of nitrate of lead, or chloride of zinc, may be substituted for it. Peat-charcoal, or the charcoal of oak bark (the refuse of tan-pits), has also a powerful deodorising action.

Several lives have been lost of late years from the crowded state of the burial-grounds of London. A deep grave was dug, and this was kept open to be piled with coffins until filled. Persons venturing into these graves were frequently suffocated. The earth in these localities is strongly impregnated with noxious exhalations; and no excavation can be made without its becoming immediately converted into a well of carbonic acid! This appears to be the poisonous gas to which fatal accidents in these localities are most commonly due. (See on this subject Henke's Zeit-
DEATH FROM LIGHTNING. 851

schrift, 1840, ii. 446; Ann. d'Hyg. 1832, 216; 1840, 131; 1843, 28, 32.)

In addition to these there are other gases and vapours of a poisonous nature which are for the most part artificial products. It is seldom that individuals are exposed to respire them in such quantity as to cause serious symptoms or to endanger life. For an account of these, I must refer the reader to my work on Poisons.

LIGHTNING. COLD. STARVATION.

CHAPTER LXIV.

LIGHTNING.

Effects of the electric fluid.—Death by lightning is sufficiently common to require that a medical jurist should be prepared to understand the phenomena which accompany it: but there is a more important reason why we should devote some attention to this subject: this is, that the appearances left by the electric fluid on the human body sometimes closely resemble those produced by extreme mechanical violence. Thus, a person may be found dead in an open field, or on the highway; his body may present the marks of contusion, laceration, or fracture; and to one unacquainted with the fact that such violence occasionally results from the passage of this subtle and invisible agent through the animal system, it might appear that the deceased had been maltreated, and probably murdered. The greater number of deaths from the electric fluid take place during the spring and summer. According to one annual report, there were 24 deaths from lightning registered during that year, occurring in the following seasons:—summer, 11; spring, 10; autumn, 2; winter, 1.

Cause of death.—The electric fluid appears to act fatally by
producing a violent shock to the brain and nervous system. In general there is no sense of pain; the individual falls at once into a state of unconsciousness. In a case which did not prove fatal, the patient, who was seen soon after the accident, was found labouring under the following symptoms. Insensibility; deep, slow, and interrupted respiration; entire relaxation of the muscular system; the pulse soft and slow; the pupils dilated, but sensible to light. (Med. Gaz. xiv. 654.) It will be seen that these are the usual symptoms of concussion of the brain. The effect of a slight shock is that of producing stunning; and, when individuals who have been severely struck recover, they suffer from ringing in the ears, paralysis, and other symptoms of nervous disorder. Insanity has even been known to follow a stroke of lightning. (Conolly’s Report of Hanwell, 1839.) In one case the individual remained delirious for three days, and when he recovered he had completely lost his memory. (Lancet, Aug. 3, 1839, 582.) Reaction may be brought about by cold affusion in cases of slight shocks.

It may be observed of the effects of lightning generally, that death is either immediate, or the individual recovers. A person may, however, linger, and die from the effects of severe laceration or burns indirectly produced. A case occurred in this city, in July 1838, where death was thus caused indirectly by the effects of electricity. The following case of recovery illustrates the action of the electric fluid:—Three persons were struck by lightning at the same time. In one, a healthy man, aged 26, the symptoms were very severe. An hour and a half after the stroke, he lay completely unconscious, as if in a fit of apoplexy;—his pulse was below 60, full and hard, his respiration snoring, his pupils dilated and insensible. There were frequent twitchings of the arms and hands; the thumbs were fixed and immovable, and the jaws firmly clenched. Severe spasms then came on, so that four men could scarcely hold the patient in his bed; and his body was drawn to the left side. When these symptoms had abated, he was copiously bled, cold was applied to the head, and a blister to the nape of the neck, with mustard poultices to the legs. Stimulating enemata and opium were also administered; in the course of twenty-four hours consciousness slowly returned, and the man soon completely recovered. The only external injury discoverable was a red streak as broad as a finger, which extended from the left temple over the neck and chest: this disappeared completely in a few days. (Brit. and For. Med. Rev., Oct. 1842.)

Appearances after death.—Generally speaking, the body, externally, presents marks of confusion and laceration about the spot where the electric current has entered or passed out;—sometimes a severe lacerated wound has existed;—on other occasions there has been no wound or laceration, but an extensive ecchymosis.
which, according to Meyer, is most commonly found on the skin of the back. In one instance which occurred in London in May 1839, there were no marks of external violence, and several similar cases are quoted from American journals in the Medical Times (May 3, 1845, p. 82). The clothes are in almost all cases rent or torn, and partially singed, giving rise to a peculiar odour, — sometimes even rolled up in shreds and carried to a distance. They are occasionally found partially burnt; but this is not a frequent occurrence. Metallic substances about the person present traces of fusion, and articles of steel have been observed to acquire magnetic polarity. Dr. West informs me, that in a case to which he was called, in which a boy, aged 18, had been instantly struck dead by lightning, he observed that a knife in the pocket of the deceased had acquired strong magnetic polarity. The case further shows that which has frequently been noticed, namely, that while much violence has been done to the dress, the parts of the body covered by it have escaped injury. The deceased wore at the time of the accident a pair of strong leather boots. These were torn to shreds, probably owing to the presence of iron nails in the soles, but the feet of the deceased presented no mark of injury! An accident by lightning occurred in the presence of a friend of mine, by which a healthy man was instantaneously killed. A cap which he wore had a hole through it. His hair was singed, his shoes were burst open, and his trousers torn. The woodwork of the building down which the electric fluid passed was merely split, and there was no mark of burning. I have examined, in several instances, the wood of trees which have been struck by the electric fluid. In each case it has presented only the appearance of rending by mechanical force.

Wounds are sometimes met with on the body. These have commonly been lacerated punctures, like stabs produced by a blunt dagger. In the case of a person who was struck, but not killed, a deep wound was produced in one thigh, almost laying bare the femoral artery. This individual was struck, as many others have been, while in the act of opening an umbrella during a storm. Fractures of the bones have not been commonly observed; in a case mentioned by Pouillet, the skull was severely fractured, and the bones depressed. (Traité de Physique, Élect. Atmosph.) The burns occasionally found on the bodies of those who have been struck by lightning, have been hitherto ascribed to the ignition of the clothes. It appears, however, from the subjoined cases, that burns even of a severe kind may be the result of a direct agency of the electric fluid on the body. Dr. Geoghegan met with the case of a girl who had been struck by lightning; there was burning of the thigh and buttocks to the first and second degrees, but the clothes did not show any signs of combustion. I am indebted to Mr. Fisher, of Dudley, for a
more detailed account of a case illustrating the same point. On the 16th of July 1855, a man, set. 23, while engaged in milking a cow in a wooden shed, during a severe thunder-storm, sud-
denly observed a vivid flash of lightning, which killed the cow instantly, and inflicted serious injuries upon him. Mr. Fisher saw him sixteen hours after the accident, and found a severe burn on his person, extending from the right hip to the shoulder, and covering a large portion of the front and side of the body. His mind was then wandering, and there were symptoms of in-
flammatory fever. The man was confined to his bed for seven-
teen days, at the end of which time the injuries had not perfectly healed. On examining his dress, the right sleeve of his shirt was found burnt to shreds, but there was no material burning of any other part of the dress. The case is curious, inasmuch as it shows that the dress may be burnt without the surface of the body being simultaneously injured, and further that a burn may be produced on the body, although the clothes covering the part may have escaped combustion.

The following complete account of the external and internal appearances found in the body of a healthy middle-aged labourer, who was killed by a stroke of lightning, has been published by Dr. Schaffer. The man was working in the fields with several other labourers, just after a thunder-storm had passed over and had apparently subsided. He was endeavouring to kindle a light with a flint and steel, when the lightning struck him. For a moment after the shock he stood still, and then fell heavily to the ground. The electric fluid entered at the upper part of his forehead, perforating and tearing his hat at that part: it seemed then to have become divided into two currents, which passed down the sides of the trunk, along the lower limbs, and out at the feet. On the upper part of the forehead was found a soft swelling, of a dark-blue colour, and about the size of the palm of a hand: the hair which covered it was uninjured. From this spot two dark-red streaks proceeded in different directions. One of these passed to the left, running over the temple, in front of the left ear, down the neck to the surface of the chest, over which it passed between the left nipple and the arm pit, and so made its way down the trunk to the left inguinal region, where it formed a large, irregular, scorched-looking (brandige) patch on the skin. From this point the dark-red streak again continued its downward course, passing over the great trochanter, then along the outer surface of the left leg to the back of the foot, where it terminated in several small dark-blue spots. The other streak, which proceeded from the ecchy-
mosed swelling on the forehead, passed directly to the right ear, which was considerably swollen and of a dark-blue colour:—
from the ear it ran downwards and backwards along the neck, crossed the right border of the scapula, and eventually reached the right groin, where a scorched patch of skin similar to that
in the left groin was found. From this part the discoloured streak continued down the outer side of the right leg to its termination on the back of the foot, just as on the left side. It is remarkable, that although the hair on the forehead, as well as that which occurred in any part of the track taken by the electric current down to the groin, was not burnt, yet at the groin itself, and at every part hence to the foot over which the electric stream had passed, the hairs were completely burnt. The cause of the skin and hair in the groins being burnt, is probably to be referred to the buckles of a belt which the man wore round his abdomen at the time of the accident: the belt was completely destroyed. Nothing further worthy of notice was observed on the exterior of the body, with the exception of the face being very red. The swelling of the head was found to be due to the presence of a large quantity of extravasated blood. The bone beneath was not injured. Blood was effused in other parts of the scalp corresponding to the swollen discoloured patches outside; about four ounces had been effused. The vessels of the cerebral membranes were much congested, and the brain itself contained a large quantity of blood, especially the choroid plexuses. A large quantity of reddish mucus was found in the larynx, trachea, and air-tubes. The lungs were loaded with dark blood; there was a great deficiency of blood in the cavities of the heart and in the large vessels. The blood-vessels of the stomach and intestines were more than usually congested. The right lobe of the liver was of a dark-red colour, and loaded with blood, especially the part which corresponded to the burnt patch of skin at the lower part of the abdomen. The spleen also was large, and loaded with blood. Much blood was found accumulated in the substance of the muscles of the abdomen, at those parts which lay beneath the burnt surfaces outside. (Österrich. Med. Wochenschrift, 6 Juni 1846.)

In another case, that of an old man killed by lightning, the external surface of the body presented slight marks of violence, except the left ear, which was severely lacerated. On opening the head, the left hemisphere of the brain was found entirely disorganized, forming a homogeneous mass, almost liquid, of a greyish colour, and without a vestige of normal structure, except a small portion of the corpus striatum which had retained its natural appearance and situation. The left lung was partly injured. The skin of the abdomen was marked by black longitudinal superficial lines. On the skin of the left ankle there was an ecchymosed spot, and at the point of the foot a deep wound. The hat and shoes of the deceased had been destroyed, but the rest of his clothes were uninjured. (Heller's Journal, Feb. 1845, 245.) The following appearances were found in the body of Professor Richman, who was killed at St. Petersburg, in 1733, while engaged in some experiments on atmospheric electri-
city. On the left side of the forehead, where the deceased had been struck by the electric current, there was a round ecchymosed spot. There were eight other patches of ecchymosis of variable size, extending from the neck to the hip, principally on the left side. Some of these, situated on the trunk, resembled the marks produced by gunpowder, when discharged in contact with the skin. The left shoe was torn open at the buckle without being singed or burnt; but the skin around was slightly ecchymosed. Internally a quantity of blood was found extravasated in the trachea, the lungs, and the layers of the omentum. The omentum presented the appearance of having been violently contused. (Marbach's Encyklopädie, Blitz.) For a further account of the effects of the electric fluid on the human subject, see Hecke, Zeitschrift der S. A. 1844, i. 193.

The blood is said not to become coagulated in the bodies of those who have been killed by lightning, while the muscles of such subjects are described as being constantly in a state of perfect relaxation, and never displaying any appearance of cadaveric rigidity. These statements are not supported by observation. Experiments carefully performed have shown that blood through which electric discharges have been transmitted, will coagulate as quickly as that which has not been thus treated; and further, Sir C. Seudamore discovered that, on examining the bodies of animals killed by the discharge of a powerful galvanic battery, the blood in the veins was always in a solid state. There is obviously, therefore, nothing in the action of the electric fluid to retard or prevent the coagulation of the blood. With respect to the alleged absence of cadaveric rigidity, there are many circumstances which may accelerate or retard the accession of this state in the dead muscle,—it may take place and disappear quickly, and the subject may not be seen at that particular time by the medical examiner. Sir B. Brodie remarked that the body of an animal killed by electricity became, as usual, rigid after death. In an accident which occurred in France in August 1846, a group of labourers was struck by the electric fluid, four were killed on the spot, and five or six severely wounded. It was remarked that the person whose body bore the most extensive marks of injury had worn a goat-skin. There were severe lacerations about the body, and in three hours after death it became perfectly rigid. In most of those who were struck, the skin was reddened, but the clothes bore no marks of burning. (Med. Gaz. xxxviii. 351.) In a case communicated to the Medical Gazette by Dr. F. J. Brown, rigidity was strongly marked in the limbs about twenty-eight hours after death. (Vol. xlvi. p. 844.) In May 1854, during a storm, a man was struck by the electric fluid. He made a short exclamation, and immediately expired. The fluid was found to have produced a burnt mark at the top of the head; it had passed down the right side of the neck and
body, thence to the left thigh and leg, and had made its exit at
the fore part of the foot, in which situation there was a livid
mark. The deceased's shirt had taken fire, and was partially
burnt. There were marks of burning on the front of the abdo-
men, and blood flowed from the left ear. The left leg of
decased's trousers, as well as the shoe and stocking, was rent
in various places. The countenance was remarkably placid.
It was observed in this case that the body became rigid after
death. Putrefaction is said to be hastened in these subjects;
but putrefaction is modified by many varying circumstances,
and death by lightning usually takes place during summer, when the process
is most readily developed. It does not appear that the process
takes place more speedily than in sudden or violent death from
any other cause. Facts are now sufficiently numerous to enable
us to say that the old opinion of the absence of rigidity, and the
acceleration of putrefaction in the bodies of persons killed by
lightning is unfounded. Dr. Bagot, of Ballingarry, has informed
me that in a case which he examined in the summer of 1855, the
body of a man, &c. 28, who had been killed by lightning, was as
rigid twenty-eight hours after death as if death had taken place
from any other cause. This man was struck on the back of the
neck, the spot being indicated by a black mark. Putrefaction
was not accelerated. In fifty-one hours after death, there was
comparatively little appearance of it. But few detailed reports
have been published of the appearances met with in the body, in
cases of death from lightning. The body of a person who
has died under these circumstances is seldom examined for a
coroner's inquest, the cause of death being sufficiently obvious.

Legal relations.—Rare as the combination of circumstances
must be, in which a medico-legal question can arise in reference
to the action of the electric fluid on the body, a case was tried in
France, in October 1845, in which medical evidence respecting
the characters of wounds caused by electricity was of consid-
erable importance. In August of that year some buildings were
destroyed at Malanay near Rouen, as it was alleged on the one
side, by a thunder storm, on the other by a whirlwind: and as
the parties were insured against lightning, they brought an action
for recovering the amount insured. The evidence in favour of
the accident having been due to electricity consisted,—1st, in the
alleged carbonized appearance of the leaves of some trees and
shrubs growing near; and 2d, in the characters of the wounds on
the bodies of several persons who were injured at the time of the
occurrence. M. Lesauvage stated at the trial, that there was an
appearance of dark stains scattered over the bodies, and those
who survived suffered from torpor, pains in the limbs, and partial
paralysis of motion. He observed also that putrefaction took
place very speedily in the bodies of those who were killed. In
one instance the muscles were torn and lacerated, and some small
arteries divided. This witness attributed most of the wounds to a
current (discharge?) of electricity. M. Funel deposed that, in some
of the dead bodies which he examined, the face and neck were
bloating and discoloured, as if death had taken place from asphyxia.
It does not appear, however, that there were any circumstances
decisively proving that the buildings had been destroyed by light-
ning. M. Pouillet has given an accurate description of the
storm: he believed that, although, as deposed to by some of the
witnesses at the trial, it may have been attended with thunder
and lightning, the buildings with the surrounding trees were
overthrown by the mere force of the wind, and not by the electric
fluid. The description given bears out this view, but at the same
time it is, I believe, a very rare circumstance that trees were
struck, unless old or dry and withered, bear any marks of com-
bustion about the leaves or trunk. (See Comptes Rendus, Sept.
1845; also Med. Gaz. xxxvi. 1133.) The scientific evidences of
the most conflicting kind. The Royal Court of Ronen de-
cided that the disaster was occasioned by the atmosphere; and
without entering into the various theories of storms, condemned
the Insurance Companies to pay the amount claimed. (Law
Times, March 14, 1846, 490.)

COLD.

An occasional cause of death.—The protracted exposure of the
human body to a low temperature may become a cause of
death; and although in this country cases but rarely occur in
which cold alone operates fatally, it is not unusual, during a severe
winter, to hear of persons being found dead in exposed situations,
and in a state of misery and destitution. On these occasions we
may reasonably suspect that the want of proper food and
nourishment has accelerated death. It is, however, convenient
to make a distinction between the effects of cold and of inanition
on the system, as the symptoms preceding death, and the rapid-
ity with which that event takes place, are very different in the
two cases.

Symptoms.—A moderate degree of cold is well known to have
an invigorating effect upon the body; but if the cold be severe,
and the exposure to it long continued, while the calorific function
is not maintained by warmth of clothing or exercise, the skin
becomes pale, and the muscles become gradually stiff and contract
with difficulty, especially those of the face and extremities. Sensi-
bility speedily disappears.—a state of torpor ensues, followed
by profound sleep from which the person cannot be readily roused:
in this state of lethargy the vital functions gradually cease, and
the individual finally perishes. Such are the general effects of
intense cold on the body. The effect of cold on the nervous
system is seen in the numbness, torpor, and somnolence which
have been described as consequences of a long exposure to a very low temperature. Giddiness, dimness of sight, tetanus, and paralysis, in some cases precede the fatal insensibility which involuntarily steals on the individual. It was observed during the retreat of the French from before Moscow, that those who were most severely affected by cold often reeled about as if in a state of intoxication,—they also complained of giddiness and indistinctness of vision, and sank under a feeling of lassitude into a state of lethargic stupor, from which it was found impossible to rouse them. Sometimes the nervous system was at once affected;—tetanic convulsions, followed by rigidity of the whole of the voluntary muscles, seized the individual, and he rapidly fell a victim. Symptoms indicative of a disturbance of the functions of the brain and nervous system have also been experienced by Arctic travellers during their residence within the Polar circle.

**Circumstances which accelerate death.—** There are certain conditions which may accelerate death from cold. In all cases where there is exhaustion of the nervous system, as in the aged and infirm,—in those who are worn out by disease or fatigue,—or, lastly, in those who are addicted to the use of intoxicating liquors, the fatal effects of cold are much more rapidly manifested than in others who are healthy and temperate. It has been uniformly remarked that, whenever the nervous energy is impaired either by intoxication or exhaustion from fatigue, the subject falls an easy victim to cold. The exposure of persons in a state of intoxication, during a severe winter, may therefore suffice to destroy life, although the cold might not be so intense as to affect others who were temperate. Casualties of this nature sometimes occur during the winter season in this metropolis; and a knowledge of the influence of intoxication in accelerating death, under such circumstances, may occasionally serve to remove any doubt in the mind of a practitioner respecting the real cause. Infants, especially when newly born, easily perish from exposure to cold. Cold, when accompanied by rain and sleet, appears to have a more powerfully depressing influence than when the air is dry,—probably from the effects of evaporation. The following case by Dr. Currie shows the fatal effects of cold winds accompanied by humidity. “Of several individuals who clung to a wreck, two sat on the only part that was not submerged; of the others, all were constantly immered in the sea, and most of them up to the shoulders. Three only perished, two of whom were generally out of the sea, but frequently overwhelmed by the surge, and at other times exposed to heavy showers of sleet and snow, and to a high and piercing wind. Of these two, one died after four hours’ exposure; the second died three hours later, although a strong healthy adult, and inured to cold and hardship. The third that perished was a weakly man. The remaining eleven, who had been more or less completely submerged, were
taken from the wreck the next day, after twenty-three hours' exposure, and recovered. The person among the whole who seemed to have suffered least was a negro: of the other survivors, several were by no means strong men, and most of them had been insul to the warm climate of Carolina."

**Appearances after death.**—Opportunities rarely occur of examining bodies when death results purely from exposure to cold. The surface is commonly pallid, and the viscera of the chest and abdomen as well as the brain are congested with blood. Dr. Kellie, of Leith, found, in two cases which he examined, a redness of the small intestines from congestion of the capillary vessels, and a great effusion into the ventricles of the brain. A sufficient number of cases have not yet been inspected to enable us to determine how far these two last-mentioned appearances are to be regarded as consequences of death from cold: but as observers have found a general congestion of the vascular system internally. In consequence of the great congestion uniformly met with in the vessels and sinuses of the brain, some pathologists have regarded death from cold as resulting from an arrest of apoplexy; but the symptoms which precede death do not bear out this view. Extravasations of blood have not been observed, and a mere fulness of the cerebral vessels after death is not in itself sufficient to justify this opinion. It will be observed that on the whole these appearances are remarkably similar to those which are found in death from severe burns and scalds. Thus, then, the medical jurist will perceive, that in order to come to a decision whether, on the discovery of a dead body, death has taken place from cold or not, is a task of great difficulty. The season of the year,—the place and circumstances under which the deceased is found,—together with the absence of all other possible causes of death (such as from violent injuries or internal disease,) form the only basis for a medical opinion. Death from cold is not to be determined except by negative or presumptive evidence, for there is no organic change either externally or internally, sufficiently characteristic of it to enable us to decide positively on the subject.

**Case of murder by cold.**—The following case involved the question of the fatal effects of cold upon the body. A man and his wife, residing at Lyons, were tried for the murder of their daughter, a girl aged eleven, under the following circumstances: —On the 28th of December, at a time when there was a severe degree of cold, the female prisoner compelled the deceased to get out of her bed, and place herself in a vessel of ice-cold water. The child cried, and endeavoured to escape from the bath; but she was by violence compelled to remain in the water. The deceased complained of exhaustion and dimness of sight: the prisoner then threw a pail of iced water upon her head, soon after which the child expired. Death was properly ascribed to
the effects of this maltreatment, and the parties were convicted. (Ann. d'Hyg. 1831, 207.) This case presents a refinement of cruelty which is rarely met with in the annals of crime. Such a case could only be proved by circumstances; for there would be no appearances in the body, internally or externally, to indicate the mode of death. We learn by this, that the death of infants or children may be caused by the external application of very cold liquids, coupled with exposure. It would also appear from this case, that the brain and nervous system are sympathetically affected through the skin, and not through the introduction of cold air into the lungs. Indeed, it is well known, from the experience of Arctic travellers, that air of a temperature considerably below zero may be respired without risk provided the skin be kept warm.

In the case of Reg. v. Lovell (Gloucester Lent Ass. 1853), a woman was convicted of the manslaughter of a child aged four years, under similar circumstances. The child it seems was in a diseased condition, and the prisoner, during the month of January, placed her under the pump in the yard, and turned the cold water upon her. The medical witness did not consider that this accelerated death, but the jury returned a verdict of guilty; and on passing sentence the late Mr. Justice Talboys observed, that the verdict was based on common sense and reason, although against the opinion of the medical witness.

STANVATION.

A rare cause of death.—Death from the mere privation of food is an extremely rare event, although, if we were to form an opinion from the verdicts of coroners’ juries, its occurrence would not appear to be very uncommon in this and other large and populous cities. In the Registration Returns for 1838–9, it is stated that 130 persons died from starvation. Such cases must, however, be received with some distrust, as care is rarely taken to ascertain precisely how far bodily disease may have been concerned in the death of the party. Still, it cannot be denied that starvation should be classed among the causes of violent death, being sometimes the result of criminal neglect or inattention in the treatment of children or of infirm and decrepit persons, and thus constituting homicide; or at other times, although very rarely, arising from an obstinate determination to commit suicide in those from whom all other means of self-destruction are cut off.

Symptoms.—The symptoms which attend on protracted abstinence are thus described by Rostan: — In the first instance, pain is felt in the epigastrium, which is relieved by pressure. The countenance becomes pale and cadaverous, — the eyes are wild and glistening, — the breath hot, — the mouth dry and parched. An intolerable thirst supervenes, which, in all cases of attempted
suicide by starvation, has formed the most prominent symptom. The body becomes emaciated, the eyes and cheeks sink, and the prominences of the bones are perceptible: the feeling of pain is often so intense as to give rise to fits of delirium. There is the most complete prostration of strength, which renders the person incapable of the least exertion. After a longer or shorter period the body exhales a fetid odour, the mucus membrane of the outlets becomes sometimes red and inflamed, and life is commonly terminated by a fit of maniacal delirium, or by the most horrible convulsions. Dr. Donovan gives the following description of those who suffered from the Irish famine in 1847:—they described the pain of hunger as at first very acute, but said that after twenty-four hours had been passed without food, the pain subsided, and was succeeded by a feeling of weakness and sinking, experienced principally in the epigastric region, accompanied with insatiable thirst, a strong desire for cold water, and a distressing feeling of coldness over the entire surface of the body. In a short time the face and limbs became frightfully emaciated, the eyes acquired a most peculiar stare; the skin exhaled a peculiar and offensive odor, and was covered with a brownish, flint-looking coating, almost as indelible as varnish. This he was first inclined to regard as incrusted filth, but further experience convinced him that it was a secretion poured out from the exhalants on the surface of the body. The sufferer tottered like a drunken man; his voice became weak, like that of a person in cholera; he whined like a child, and burst into tears on the slightest occasion. In respect to the mental faculties, their prostration kept pace with the general wreck of bodily power; in many there was a state of imbecility; in some, almost complete idiosexotism; but in no instance was there delirium or mania, which is often described as a consequence of protracted abstinence among shipwrecked mariners. (Dub. Med. Press, February 1848, p. 67.)

Period of death.—The period which it requires for an individual to perish from hunger is subject to variation. It will depend materially upon the fact, whether a person has it in his power or not to take at intervals a portion of liquid to relieve the overpowering thirst which is commonly experienced. The smallest portion of liquid thus taken occasionally, is found to be capable of prolonging life. It is probable that in a healthy subject under perfect abstinence, death would not commonly take place in a shorter period than a week or ten days. This opinion appears to derive support from the results of those cases in which there has been abstinence owing to disease about the organs of deglutition.

Appearances after death.—There are no very satisfactory details of the appearances presented by the bodies of those who have died of starvation, and the cases themselves are too rare to enable us to decide with certainty upon the accuracy of the reports
which have hitherto appeared on the subject. The body has been found much emaciated, the skin dry, and the stomach and intestines contracted and empty, the mucous membrane sometimes ulcerated; the gall-bladder much distended with bile; the lungs, heart, and great vessels connected with these organs, collapsed and destitute of blood. The following account of the appearances met with in a fatal case of starvation has been published by Dr. Sloan, of Ayr. A healthy man, aged 65, was by an accident shut up in a coal-mine twenty-three days. For the first ten days he was able to procure and swallow a small quantity of foul water. When found, he could not make the least exertion, nor could he speak above a whisper. Attempts were made to restore him, but he died in three days, perfectly exhausted. On inspection, the body was observed to be extremely emaciated: the intestines were collapsed, the stomach was distended with air, and slightly reddened at its greater extremity. The liver was small, and the gall-bladder distended. The other viscera were in their normal state. (Med. Gaz. xvii. 389.) Mr. Tomkins, of Yeovil, inspected the body of a man who died from starvation in February, 1838. The face was much shrunk and emaciated; the eyes open, and presenting a fiery red appearance, as intense as in a case of acute ophthalmia during life. This red appearance has been met with by Dr. Donovan in death from exposure to cold. (Dublin Med. Press, Feb. 2, 1848, p. 66.) The skin was tough, and there was scarcely any cellular membrane to be seen. The tongue, lips, and fauces were dry and rough. A peculiar odour exhaled from the body. The lungs were shrunk and contracted; the pleura was slightly inflamed. The stomach and intestines were empty, but quite healthy; the gall-bladder was nearly full of bile, and the surrounding parts were much tinged by this liquid. The urinary bladder was empty and contracted. (Lancet, March 1838.) In some cases inspected during the Irish famine, Dr. Donovan states that the appearances which he witnessed were extreme emaciation, total absorption of the fatty matter on the surface of the body, total disappearance of the omentum, and a peculiar thin condition of the small intestines, which, in such cases, were so transparent, that if the deceased had taken any food immediately before death, the contents could be seen through the coats of the bowel; on one occasion (at an inquest), he was able to recognise a portion of raw green cabbage in the duodenum of a man who had died of starvation. This thin condition of the coats of the intestines he looks upon as the strongest proof of starvation. The gall-bladder was usually full, and the parts in the vicinity of it were much tinged, from the cadaveric exudation of bile; the urinary bladder was generally contracted and empty, and the heart pale, soft, and flabby; there was no abnormal appearance in the brain or lungs. Mr. Fletcher found the following appearances in the cases of two children, named Aspinall, who died
from starvation, the elder aged one year and ten months, the younger four months. In the body of the elder there was extreme emaciation, without the slightest trace of disease in any of the viscera. Some dirty creamy fluid and four cherry stones were found in the small intestines, but no distinctly focal matter, a few grains of which, however, were found in the large intestines. Scarcely a trace of fat was visible. In the infant the same appearances were presented, although the emaciation had not proceeded to the same extent. The evidence produced on the trial proved that the mother spent in drink the money given her for household expenses, and that the children's food and clothing were neglected. The prisoners were tried for wilful murder, in accordance with the verdict of the coroner's jury. The judge told that as the wife was in law the husband's servant, if it were proved that he had supplied her with sufficient money, he must be acquitted; if he had not, the wife must be acquitted. The jury acquitted the man and brought in a verdict of manslaughter against the woman, who was sentenced to two years' imprisonment. (Proceedings of Liverpool Medical Society, 1835-6.)

Summary of medical evidence.—These appearances, in order to throw any light upon the cause of death, should be accompanied by an otherwise healthy state of the body; since, as it is well known, they may be produced by many organic diseases; and death may be thus due to disease, and not to the mere privation of food. It will not, therefore, be easy to say whether the emaciation depends on disease or want of food, unless we are in possession of a complete history of the case. On this account, in all charges of homicidal starvation, the defence generally rests upon the co-existence of disease in the body, and the sufficiency of this to account for death. In some of these alleged deaths by starvation, ulceration of the bowels is met with. This has been considered to arise from want of food; but Dr. Donovan did not meet with it in those who died of lingering starvation. (Dublin Med. Press, Feb. 2, 1848, 66.) See, in reference to medical evidence on this subject, the case of the Queen v. Price, Chelmsford Summer Ass. 1840.

Legal relations.—Starvation is commonly the result of neglect or homicide; but this is a question purely for the decision of the jury; it cannot be elucidated by medical evidence. The withholding of food from an infant forms a case of homicide by starvation, on which a medical opinion may be occasionally required. Mr. Baron Gurney held that the mother, and not the father, was bound to supply sustenance to an infant. The child in this case was ten weeks old, and the father was charged with wilful murder on the ground that he had not supplied it with food. The grand jury ignored the bill under the instructions of the judge, upon the ground above stated. (The King v. Davey, Exeter Lent Ass. 1835.) But it is probable that there were particular cir-
cumstances in this case which led to this decision. The facts may be of such a nature as to inculpate the father, by proving that he was accessory to the death of the child. But where the husband and wife were charged with the murder of an apprentice to the husband, by using him in a barbarous manner, and the opinion of the medical witness was, that the boy had died from debility occasioned by a want of proper nourishment, it was held that the wife was entitled to be acquitted, as it was the duty of the husband, and not of the wife, to provide sufficient food and nourishment for the apprentice. (The King v. Squire, Starkie, ii. 947.) Starvation is rare as an act of homicide, but it must not be supposed that the law implies by this the absolute privation of food; for if that which is furnished to a person be insufficient in quantity, or of improper quality, and death be a consequence, malice being at the same time proved, then the offender equally subjects himself to a charge of murder. Some years since, a woman who was accustomed to take parish-apprentices was tried and convicted of the murder of two children, who had died in consequence of the bad quality and small quantity of food furnished to them by the prisoner.
INSANITY.

CHAPTER LXV.

Legal definitions.—The law of England recognises two states of mental disorder or alienation. 1. Dementia naturalis, corresponding to idiocy; and 2. Dementia adventitia, or accidentalis, signifying general insanity as it occurs in persons who have once enjoyed reasoning power. To this state the term lunacy is also applied, from an influence formerly supposed to be exercised by the moon on the mind. Lunacy is a term generally applied by lawyers to all those disordered states of mind which are known to medical men under the names of mania, monomania, and dementia; and which are generally, though not necessarily, accompanied by lucid intervals. The main character of insanity, in a legal view, is said to be the existence of delusion: i.e. that a person should believe something to exist which does not exist, and that he should act upon this belief. Many persons may labour under harmless delusions, and still be fitted for their social duties; but should these delusions be such as to lead them to injure themselves or others in person or property, then the case is considered to require legal interference.

Unsoundness of mind.—Besides the terms Idiocy and Lunacy, we find another frequently employed in legal proceedings, namely, "unsound mind"—(non compos mentis)—of the exact meaning of which it is impossible to give a consistent definition. From various legal decisions it would appear that the test for unsoundness of mind in law has no immediate reference to the mere existence of delusion, so much as to proof of incapacity in the person, from some morbid condition of intellect, to manage his own affairs. (Amos.) Neither condition will suffice to establish
unsoundness without the other; for the intellect may be in a morbid state, and yet there may be no legal incompetency, or the incompetency alone may exist, and depend on bodily infirmity or want of education—a condition which must not be confounded with insanity. Thus, then, a person may be of unsound mind, i.e. legally incompetent to the control of his property, and yet not come up to the strict legal standard of lunacy or idiocy. Hence it will be seen that it is impossible, in medical jurisprudence, to give any consistent definition of insanity. A medical witness who ventures upon a definition will generally find himself involved in numerous inconsistencies. No definition can possibly comprise the variable characters which this malady is liable to assume. The power which is most manifestly deficient in the insane is generally the controlling power of the will.

Some medical practitioners have attempted to draw a distinction between 
insanity and unsoundness of mind. A case occurred in 1839, in which a medical man hesitated to sign a certificate for the confinement of an alleged lunatic, because in it the terms "unsound mind" were used. He said he would not have hesitated to sign it had the term "insane" been employed. The difference, if any exist, is purely arbitrary, and depends on the fact, that unsound mind is a legal and not a medical phrase, referring to an incapacity to manage affairs, which insanity, in its most enlarged sense, may not always imply. The law, however, appears to admit some sort of distinction, for, according to Chitty, it is a criminal and an indictable act maliciously to publish that any person is afflicted with insanity, since it imputes to the party a malady generally inducing mankind to shun his society; although it is not libellous to say that a man is not of sound mind, because no one is of perfectly sound mind but the Deity! (M. J. i. 351.) In reference to the refusal to sign certificates, it is, however, an error to suppose that the use of one term can involve a practitioner in a greater share of responsibility than the use of the other.

Varieties of insanity.—Medical jurists have commonly treated insanity under four distinct forms: Mania, Monomania, Dementia, and Idiocy (Amentia). This division was proposed by Esquirol, and although of a purely artificial nature, it is convenient for the arrangement and classification of the facts connected with the subject. In some instances there is great difficulty in assigning a particular case to either of these divisions, which is owing to the circumstance, that these states of mind are frequently intermixed, and are apt to pass and repass into each other. On other occasions, a case may present characters which appertain to all the divisions. Some psychologists have proposed two subdivisions, namely, Incoherency and Imbecility; but the former is merely a mixed state of mania and dementia, while the latter is a term applied to those cases of idiocy wherein the mental facult-
ties are susceptible of cultivation after birth, without reaching the normal standard. In a work on Medical Jurisprudence, it will be only necessary to state briefly the principal features of each of these varieties of insanity.

Mania.—In this form of insanity, there is a general derangement of the mental faculties, accompanied by greater or less excitement, sometimes amounting to violent fury. The individual is subject to hallucinations and illusions, the difference in the meaning of which terms it may here be proper to explain. Hallucinations are those sensations which are supposed by the patient to be produced by external impressions, although no material objects may act upon the senses at the time. (See on this subject remarks by Dr. Sigmund, Journal of Psychol. Med. 1848, p. 585.) Illusions are sensations produced by a false perception of objects. (Mare). When a man fancies he hears voices, while there is profound silence, he labours under a hallucination: when another imagines that his ordinary food has an earthy or metallic taste, this is an illusion. Illusions sometimes arise from internal sensations, and give rise to the most singular ideas. When a hallucination or an illusion is believed to have a real and positive existence, and this belief is not removed either by reflection or an appeal to the other senses, the individual is said to labour under a delusion: but when the false sensation is immediately detected, and is not acted on as if it were real, then the person is sane. Perhaps this is the most striking distinction which it is in our power to draw between sanity and insanity. Illusions refer to the senses,—delusions to the judgment. The acts of the insane are generally connected with their delusions; but it is extremely difficult to trace the connection between them, except by their own confession. It has been remarked, that in mania there is great insensibility to changes of temperature; but it must not be inferred from this that the patient is less susceptible than a sane person of the injurious effects of cold. The bodily susceptibility of insane persons is just as great, while they want that warning power which the sense of feeling gives to one who is sane.

The death of a lunatic of the name of Dolley, at the Surrey Lunatic Asylum in March 1856, was ascribed to the effects of a cold shower-bath, continued for an unusual period: this case involved a serious question respecting the medical treatment of the insane. The patient, age 65, was exposed to a shower-bath for half an hour, at a temperature of 45°, and, after removal from this, a full dose of tartar emetic was given to him. The man died in about a quarter of an hour, and a coroner's jury returned a verdict to the effect that death was caused by this treatment. The grand-jury threw out the bill, and Mr. Sapse, the medical gentleman implicated, was exonerated by a medical committee, and subsequently reinstated in his office. The treatment was in this case
adopted bona fide: but nevertheless, if frequently carried out to the same extent, it would expose the lives of aged lunatics to great risk.

It is necessary that a medical jurist should be able to distinguish mania from delirium depending on bodily disease. Delirium very closely resembles the acute form of mania,—so closely that mistakes have occurred, and persons labouring under it have been improperly ordered into confinement as maniacs. The following are perhaps the best diagnostic differences. A disordered state of the mind is the first symptom remarked in mania; while delirium is a result of bodily disease, and there is greater febrile excitement in it than in mania. Delirium being a mere symptom attendant on the disease which produces it, exists so long as that disease, and no longer; while mania, depending on very different causes, is persistent. Delirium disappears suddenly, leaving the mind clear; while mania commonly experiences only remissions. (See Pagan, M. J. of Ins. 69.) In delirium there is generally great acuteness of the senses.

Monomania.—This name is applied to that form of insanity in which the mental alienation is partial. The delusion is said to be confined either to one subject or to one class of subjects. One fact is well ascertained, that monomania varies much in degree; for many persons affected with it are able to direct their minds with reason and propriety to the performance of their social duties, so long as these do not involve any of the subjects of their delusions. Further, they have occasionally an extraordinary power of controlling their thoughts and emotions, as well as of concealing the delusions under which they labour. This implies a consciousness of their condition not met with in mania; and it also appears to imply such a power of self-control over their thoughts and actions, as to render them equally responsible with a sane person for many of their acts. In a real case of monomania, it is not to be supposed that a man is insane upon one point only, and sane upon all other matters. The only admissible view of this disorder is that which was taken by Lord Lyndhurst, in one of his judgments. In monomania, the mind is unsound; not unsound in one point only, and sound in all other respects, but this unsoundness manifests itself principally with reference to some particular object or person. (Prichard.) There is no doubt that all the mental faculties are more or less affected; but the affection is more strikingly manifested in some than in others. I have had frequent occasion to witness this form of insanity among persons who believed that they had taken poison or were labouring under its effects, while on other points I could detect no intellectual aberration. Monomania is very liable to be confounded with eccentricity: but there is this difference between them. In monomania, there is obviously a change of character,—the individual is different from what he was; in eccentricity
such a difference is not remarked; he is and always has been singular in his ideas and actions. An eccentric man may be convinced that what he is doing is absurd and contrary to the general rules of society, but he professes to set these at defiance. A true monomaniac cannot be convinced of his delusion; he firmly believes that his impressions are well founded and that his acts are consistent with reason. In eccentricity there is the will to do or not to do: in real monomania the controlling power of the will is either impaired or lost. The current of thought involved in the delusion cannot be controlled or expelled. Eccentric habits suddenly acquired are, however, presumptive of insanity. The distinction of these states is of considerable importance in relation to testamentary capacity.

Many medico-legal writers consider that insanity is not necessarily confined to a disturbance of the intellectual powers; they hold that it may also show itself without decided intellectual aberration in the feelings, passions, and emotions. Thus it may appear under the form of a causeless suspicion, jealousy, or hatred of others, especially of those to whom the individual ought to be attached; and it may also manifest itself under the form of a wild, reckless, and cruel disposition. This is what has been called by Dr. Prichard "Moral insanity," to distinguish it from the other form which affects the mental (reasoning) powers directly, namely, "Intellectual insanity." It does not appear probable, however, that moral insanity ever exists or can exist in any individual without greater or less disturbance of the intellectual faculties. The mental powers are rarely disordered without the moral feelings partaking of the disorder: and conversely it is not to be expected that the moral feelings should become to any extent perverted without the intellect being affected, for perversion of moral feeling is generally observed to be an early symptom of disturbed reason. The intellectual disturbance may be sometimes difficult of detection; but in every case of true insanity it is more or less present, and it would be a highly dangerous rule to pronounce a man insane, when some evidence of its existence was not forthcoming. The law does not recognise moral insanity as an independent state; hence, however perverted the affections or moral feelings may be, a medical jurist must look for some indications of disturbed reason. Medically speaking there are, according to Dr. Prichard, two forms of insanity, moral and intellectual: but in law there is only one. Moral insanity is not admitted as a bar to responsibility for civil or criminal acts except in so far as it may be accompanied by intellectual disturbance. Dr. Mayo denies its existence, and contends that no abnormal state of mind should confer irresponsibility unless it involve intellectual as well as moral perversion (Medical Testimony, p. 69). With respect to the term monomania it does not, according to this author, imply unity of delusion but permanency and predominance in some one delusion.
Monomania may be accompanied with a propensity to homicide or suicide, and, according to some psychologists, with a disposition to incendiaryism or theft. These forms will be referred to hereafter, in speaking of the criminal responsibility of the insane.

Dementia.—In this state there is a total absence of all reasoning power:—the mental faculties are not perverted, but destroyed. There is a want of memory as well as a want of consciousness, on the part of the individual, of what he does or says. It is by no means an unfrequent consequence of mania or monomania,—but it has been known to occur suddenly in individuals, as an effect of a strong moral shock.

Idiocy. Imbecility.—Idiocy is characterised by the want of mental power being congenital. While mania, monomania, and dementia, form the "dementia accidentalis," idiocy forms the "dementia naturalis" of lawyers. This intellectual deficiency is marked by a peculiar physiognomy, an absence of all expression, and a vague and unmeaning look, whereby an idiot may in general be clearly identified. In many cases of congenital deficiency, the mind is capable of receiving a few ideas, and of profiting to a certain extent by instruction. To this state the term Imbecility is applied. It may be regarded as a minor degree of idiocy. The mind of an imbecile can never be brought to a healthy standard of intellect, like that of an ordinary person of the same age. The degree to which congenital deficiency of intellect exists, is generally well marked by the power of speech, or of communicating ideas by language. In idiocy there is no speech, or only an utterance of single words; in the better class of imbeciles, the speech is but little affected; while there is every grade between these two extremes. Some medical jurists have arranged imbeciles in classes, according to their capacity to receive instruction; others, according to their power of speech; but such divisions are practically without value; each case must be judged by itself. It is by no means easy to draw a distinction between the better classes of imbeciles, and those who are reputed sane,—since the minds of sane persons differ remarkably in their capacity to receive instruction. It has been well observed, that by endeavouring to make a very close distinction of this kind, one half of the world might reason itself into the right of confining the other half, as insane! Persons affected with idiocy and imbecility do not suffer from hallucinations and illusions, like those who labour under mania or monomania. Idiots and imbeciles are what they always have been; there is no gradual loss or impairment of the intellectual functions. The term imbecility is often applied to that loss of mental power which takes place as a result of extreme age; but this is with greater propriety called senile dementia.

Such are the forms under which insanity or mental alienation...
may present itself to our notice. This medical classification has
been adopted for the sake of convenience; because by it a prac-
titioner may be led to form a safe diagnosis of the real state of mind
of a person. It is not recognised in any of the law-proceedings
connected with the insane: for in these the term unsoundness of
mind, comprehending lunacy and idiocy, is almost exclusively
employed. In adopting this arrangement, a medical jurist must
take care not to fall into an error which has been sometimes com-
mited, i.e. of pronouncing a person to be of sound mind, because
his case could not be easily placed in any one of these four great
divisions of insanity. This would be as serious an error as that
formerly committed by some law-writers, namely, of giving re-
stricted and incorrect definitions of lunacy and idiocy, and
then contending that, whoever was not a lunatic or idiot accord-
ing to these arbitrary legal definitions, must be a person of sound
mind!

Appearances after death.—In some cases a medical practitioner
may be required to state whether certain appearances found in the
brain of a deceased person do or do not indicate the past existence
of a certain degree of insanity or imbecility? Such a question
is only likely to arise in chronic cases, in which the past existence
of insanity from oral testimony may be disputed. (Case of Stuk,
Prerog. Court, 1852.) The appearances commonly met with on
an inspection are, thickening of the bones of the skull, close ad-
hesions of the dura mater (the lining membrane), with great
congestion of the pia mater, and opacity and thickening of the
arachnoid membrane. There is general fulness of the blood-
vessels of the brain, with remains of cysts, hardened deposits, or
even abscesses in various parts of the substance of the brain.
Inferences from the existence of these changes in the brain must
be drawn with caution, because it cannot be said that they
necessarily indicate insanity; nevertheless, such chronic changes
in the brain must be considered as producing greater or less derangement of the mental functions; but the actual degree to
which the impairment has existed ought properly to be deter-
mined by evidence of the conduct and actions of the deceased
during life. In a communication made by Dr. Webster to the
Medico-Chirurgical Society in April 1855, there is a statistical
summary of the appearances met with in the examination of the
bodies of 290 insane patients. In 226 cases the pia mater was
infiltrated; in 207, effusion had taken place into the ventricles;
in 184, fulness of the blood-vessels in the brain or membranes
was observed; in 117, the arachnoid membrane was thickened
and opaque; in 64, the colour of the brain appeared changed
from its natural hue; in 51, the bloody points were large and nu-
erous upon the cut surface of the medullary substance; whilst
in 40 instances blood was effused, sometimes to a considerable
extent, within the cranium. This effusion had evidently been the
immediate cause of death in most of these patients. From these data it appears that—First, infiltration of the pia mater; secondly, effusion of fluid in the ventricles; thirdly, fulness of the cranial vessels, are the principal as also the most frequent diseased alterations of structure observed in patients who die whilst suffering under symptoms of mental alienation.

As neither the symptoms nor the duration of the insanity is given, it is difficult to apply these results to special cases. In the case of *Roberts v. Kerstake*, (Warwick Aut. Assizes, 1854,) the main question was whether certain appearances in the brain and its membranes did or did not indicate disease of long standing, as well as insanity at the particular date at which a will was made. Dr. Conolly and I considered that the appearances were not inconsistent with the supposition that the testator was sane at the time of making his will. (Journal of Psychological Med., Oct. 1854, p. 573.) The reader will find some valuable information on this subject in a paper by Mr. Fisher (Med. Gaz. xxxvii. p. 657); and in another by Mr. Eccleston (Med. Gaz. xlvi. p. 170); also in some contributions to the Journal of Psychological Medicine (1850, p. 521, and 1851, pp. 236 and 383), by Mr. Holmes Cooto. See also Dr. Jamieson’s Lectures, Med. Gaz. xlvi. p. 652; and a paper by Dr. Webster, Journal of Psychol. Med. 1849, p. 483; by Dr. Farre, in same volume, p. 534; and by Dr. Hitchman, in the volume for 1850, pp. 228, 362, 501.

*Hereditary transmission.*—The hereditary transmission of insanity has sometimes presented itself as a medico-legal question in relation to the criminal responsibility of the insane. According to Chitty, it is an established rule of law, “that proof that other members of the same family have decidedly been insane is not admissible either in civil or criminal cases.” (Med. Jur. i. 352.) But recent decisions have shown that this statement is not correct. In the case of *Reg. v. Ross Touchet*, 1844, tried and acquitted on the ground of insanity for shooting a man, Maule J. held that evidence that the grandfather had been insane may be adduced, after it has been proved by medical testimony that such a disease is often hereditary in a family. It was also admitted in *Oxford’s case*,—the prisoner having been here tried for shooting at the Queen. (Law Times, Oct. 26, 1844.) This kind of evidence has, however, been frequently rejected, and it is not admitted in the law of Scotland. (Gibson’s case, Edinburgh, Dec. 1844.) There can be no doubt, from the concurrent testimony of all writers on insanity, that a predisposition to the disease is frequently transmitted from parent to child through many generations. The malady may not always show itself in such cases, because the offspring may pass through life without being exposed to any exciting cause; but in general it readily supervenes from very slight causes. M. Esquirol has remarked, that this hereditary taint is the most common of all the causes to which insanity can be referred, especially as it exists among the
higher classes of society. Among the poor, about one sixth of all the cases may be traced to hereditary transmission; and other authorities have asserted that, in more than one half of all cases of insanity, no other cause can be found for the malady. As we might suppose, children that are born before insanity manifests itself in the parents, are less subject to the disorder than those which are born afterwards. When one parent only is insane, there is less tendency for the predisposition to be transmitted than when both are affected: but according to Esquirol, this predisposition is much more readily transmitted through the female than through the male parent. Its transmission is also more strikingly remarked when it has been observed to exist in several generations of lineal ancestors; and, like other hereditary maladies, it appears to be subject to atavism; i.e., it may disappear in one generation, and reappear in the next. Further, the children of drunken parents, and of those who have been married late in life, are said to be more subject to insanity than those born under other circumstances. When insanity is transmitted by hereditary descent, it appears often about the same age, under the same form, and is induced by the same exciting cause in the offspring as in the parent. This it is proper for a medical jurist to bear in mind, in examining a plea of insanity in criminal cases. (See Journal of Psychol. Med. 1848, p. 264.)

Statistics.—The valuable tables of Esquirol show that the age at which insanity most commonly attacks persons is thirty;—it rarely makes its appearance below the age of twenty, or above the age of fifty-five. According to a Report published by the Commissioners of Lunacy for 1850, there were in that year under their supervision in England and Wales, 15,079 lunatics; namely, 7074 males, and 8005 females. Of these, 11,305 belonged to the pauper class; and of the whole number, 7140 were confined in asylums. According to their Report, dated March 31st 1856, it appears that on the 1st January 1856 the number of lunatics amounted to 20,764; namely, 9701 males, and 11,063 females. Of these, 20,643 are thus accounted for. There were in asylums 13,823; in hospitals, 1628; in metropolitan licensed houses, 2591, and in provincial licensed houses, 2601. Dr. Jamieson has published in his lectures some curious facts regarding the statistics of insanity, to which I must refer the reader (Med. Gaz. xlvi. p. 269); and an able analysis of the Commissioners’ Report will be found in the Journal of Psychol. Med. 1850, p. 111.

Feigned insanity.—Insanity is frequently feigned by persons accused of criminal offences, in order to procure an acquittal or discharge. In the first place, when this is suspected, it will be proper to inquire whether the party has any motive for feigning the malady. It is necessary to remember that insanity is never assumed until after the commission of a crime and the actual detection of the criminal. No one feigns insanity merely to
CASES OF FEIGNED INSANITY.

avoid suspicion. In general, as in most cases of imposture, the part is over-acted; the person does either too much or too little, and he betrays himself by inconsistencies of conduct and language which are never met with in real cases of insanity. There is commonly some probable cause to which real insanity may be traced, but when the malady is feigned there is no apparent cause; in this case the appearance of the assumed insanity is always sudden; in the real malady, the progress of an attack is generally gradual, and, when the attack is really sudden, then it will be found to be due to some great moral shock or other very obvious cause. We should observe whether there has been any marked change of character in the individual, or whether his conduct, when he had no interest to feign, was such as it is now observed to be. Some difficulty may arise when fits of eccentricity or strangeness of character are deposed to by witnesses; but these statements may be inconsistent with each other, and the previous acts of the person may bear no resemblance whatever to those performed by him in the recently assumed condition. A difficulty of this kind rarely presents itself, since, in an impostor, no act indicative of insanity can be adduced for any antecedent period of his life: it is only after the perpetration of a crime and its detection, that any action approaching to insane habits will be met with. In real insanity, the person will not admit that he is insane; in the feigned state, all his attempts are directed to make you believe that he is mad; and an impostor may be induced to perform any act, if it be casually observed to another in his presence that the performance of such an act will furnish strong evidence of his insanity.

I am indebted to a learned judge for the following note on feigned insanity:—"It may be safely held that a person feigning insanity will rarely, if ever, try to prove himself to be sane,—for he runs the great risk of satisfying others that he is sane,—the conclusion he desires to avoid. But there is no better proof, in general, that the insanity (supposing other evidence of it to be strong) is real, than keen eager attempts by the accused to prove that he is sane, and strong and indignant remonstrances against being held to be insane, although that would protect himself against trial and punishment. In one case at Edinburgh some doubt existed whether a party was feigning insanity; and some of those about him, and in charge of him in gaol, from his clearness and coherence, were satisfied that he was quite sane, and that what he exhibited was merely eccentricity, or simulated attempts to act as a madman. Insane he certainly was, beyond all doubt; but he fought the point of his sanity most bravely in court, made very clear and quick remarks on the evidence of the medical men, who had no doubt of his entire insanity; and, when one physician of great experience with insane persons stated that he thought him quite incapable of giving information to counsel and agent for conducting his defence, he said instantly,
Then why did you advise me to apply to, and see, counsel and agents?"

Mania is perhaps more frequently assumed than any other form, because the vulgar notion of insanity is, that it is made up of violent action and vociferous and incoherent language; but mania rarely comes on suddenly, or without an obvious cause: the patient is also equally furious by day and by night, while the impostor is obliged to rest after his violent exertions. Dr. Burrow recommends that close attention should be paid to the expression of the eye. The mobility of the features may be as rapid as the imagination is vivid; but when every feature may vary, or be kept under control and be steady, the eye will still indicate the erring thought. Its expression cannot be easily assumed. In mania the person sleeps but little, and the sleep is disturbed; an impostor sleeps as soundly as a healthy individual:—the violence of the maniac continues whether he is alone or not; while the impostor acts his part only when he thinks he is observed; hence the imposition may be detected by watching him when he is not aware that an eye is directed upon him.

Some stress has been laid on the fact, that assumed insanity commonly appears suddenly and without probable cause; but while this may be allowed to have a general value in forming a diagnosis, it is proper to bear in mind that the actual commission of a crime has sometimes suddenly led to an attack of mania in a previously sane person. Dr. Paget has related a very singular instance of this kind. Two men were committed to prison on a charge of theft, and the officers requested a poor man, who was a shoemaker, to assist them in conveying the prisoners. The man took a gun with him for better security. During the journey, one of the prisoners leaped from the cart and ran off. The officers called to their assistant to fire, and he thinking himself warranted to do so, fired, and wounded the prisoner severely in the back and loins. The man who fired the gun was himself immediately committed to gaol as a criminal, and the event made such an impression upon him that he became violently maniacal. When scarcely recovered, he was tried for the offence; and it was supposed that he was feigning insanity. He was convicted and sentenced to six months' imprisonment. (Med. Jur. of Ins. 82.) This case proves that a person may really be attacked by mania under circumstances in which a justifiable suspicion might arise that he was feigning.

The feigning of Manomani would be a matter of some difficulty, and easily susceptible of detection. Dementia is more easily feigned:—in general this state comes on slowly, and is obviously dependent on organic changes, as old-age, apoplexy, paralysis, or hemiplegia, or it is a consequence of long-continued mania or monomania. As this form of insanity consists in an entire abolition of all mental power, so the discovery of any
connected ideas, reasoning or reflection either by language writing or gestures, would at once show that the case was not one of real dementia. *Idiocy* and *imbecility* could hardly be feigned successfully, because these are states of congenital deficiency; and it would be easy to show, by reference to the past life of a person, whether he had or had not always been such as he represents himself. The difficult cases of feigned insanity are really limited to those forms of the malady which are liable to attack an individual suddenly. In a sudden attack of real insanity, there should be some obvious cause: the non-existence of this, with the presence of a strong motive for deception, will always justify a suspicion that the malady has been assumed.

The following is a case of feigned insanity which was the subject of a trial in London some years since. It may be taken as a type of this kind of imposture. A married woman, aged fifty, was charged with uttering a forged cheque: she had craftily procured the signature of a person under a false pretence, and then forged his name to the cheque. When required to plead, she made no answer, and appeared unconscious of the question. She took up some flowers placed in the dock, and crumbled them in her fingers, which were in continual motion. She stared wildly at times, changing her position,—turned her back on the court,—muttered indistinct exclamations, and made a humming noise. She was placed under some restraint, in order to prevent her from jumping out of the dock. The first question which the jury was directed to try was whether she was of "sound mind or not;" it being a rule of law that no insane person can be called on to plead to an offence committed by him. Evidence was then adduced to show that at previous periods of her life she had used incoherent language and was strange in her conduct. It was also shown that her mother, aunt, and sister had been insane. Dr. Uwins deposed that at first he thought the prisoner was feigning, for she appeared to be fully aware of the importance of the plea of insanity, but when he heard that other members of her family had had the disease, he was induced to think her insane, and not accountable for her actions. Another medical witness, who had attended her family professionally, and had known the prisoner long, thought she was not insane, although he allowed that the apprehension of a criminal charge might bring on an attack of insanity in a mind subject to aberration. Other witnesses deposed that they had never observed any acts of insanity about her; and it was further proved that she was well acquainted with the method of drawing and procuring money on bills. When arrested, she tried to escape from the officer, and to conceal the money which she had procured by means of the forged check. The surgeon of the gaol thought she was feigning: he visited her daily, and he observed that her manner changed so soon as she saw him. When asked what counsel she
would employ, she returned a rational answer, saying that: "others would take care of that:" when charged with feigning, she made no observation. She put on a wild look when she knew that she was observed; but, when privately watched, her behaviour was that of a rational person: she generally slept soundly. The jury returned that she was of sound mind. She was then called on to plead to the charge, but she refused; a circumstance rarely observed in the conduct of a really insane person. She was tried, and found guilty of the charge. There could be no reasonable doubt that this woman was an imposter, and that she feigned insanity, well knowing what would be the result of the plea, if admitted. Two circumstances rather tended to complicate the case: 1. the proof of hereditary predisposition. 2. her assumed silence, whereby she did not easily betray herself. In regard to hereditary predisposition, although valuable as collateral evidence, it cannot, of course, be allowed to outweigh general facts indicative of perfect sanity. At the Lewes Winter Assizes, Dec. 1856, (Reg. v. Ball) the prisoner, a ticket-of-leave convict, was convicted of house-breaking, and sentenced to fifteen years' transportation. This case shows how easily medical men may be deceived by skilful imposters who feign insanity. After the prisoner had been committed to gaol he simulated madness successfully that he deceived three of the visiting justices as two medical men; and a certificate was about to be signed for his removal to a lunatic asylum, when the deception was discovered by the man having made a confidant of one of his fellow-prisoners. He had been convicted of robbery at Leicester in 1851, and sentenced to ten years' transportation; he was sent to Millbank prison, where he feigned insanity and succeeded in deceiving the medical officers, who certified that he was a lunatic, and he was accordingly removed to Bethlehem Hospital where he remained two years. He subsequently received a ticket-of-leave.

For a singular case in which a verdict was returned against a strong medical evidence of alleged insanity, see Lancet, January 18, 1843, p. 70: Med. Gaz. xlvi. p. 49; Journ. Psychol. Med. 1848. p. 277; also, Ann. d'Iyg. 1829, ii. 367, 376, and a case by Dr. Bayard, Ann. d'Iyg. 1847, ii. 230.

CHAPTER LXVI.

MEDICO-LEGAL QUESTIONS IN RELATION TO THE INSANE — IMPOSITION OF RESTRAINT — ILLEGAL IMPOSITION OF RESTRAINT — VIOLENCE OF TEMPER — CERTIFICATES OF INSANITY — RULES FOR THE DISCHARGE OF LUNATICS.

Medico-legal questions. — Among the questions which may come before a medical jurist, in relation to the subject of insanity, are
INSANITY. IMPOSITION OF RESTRAN. 879

be following:—A practitioner may be required to say whether a person affected with the malady should or should not be con-

fined in a lunatic asylum,—whether he should be deprived of his civil rights by interdiction, or whether he is so completely cured of his malady as to justify his liberation from confinement.

Then, again, medical evidence may go far to determine whether a will or deed, executed by an alleged lunatic, should be set aside; whether a marriage-contract should be annulled; and, lastly, whether a criminal act was committed by a person labouring under insanity,—a question involving either the life or, according to circumstances, the perpetual imprisonment of an accused party.

Imposition of restraint.—By this we are to understand the separation of a lunatic from his friends or relatives, with or without the confinement of his person by force. What are the circumstances which will justify a practitioner in applying restraint to the insane? The law has given great power in this respect to members of the medical profession, but, owing to certain abuses, this power has been of late years much restricted by various acts of the legislature. Most medico-legal writers agree that we are never justified in ordering restraint, except when from the symptoms we have reason to apprehend that the lunatic will injure his person or property, or the persons or property of others. It is then not sufficient to seek merely for evidence of delusion; but, if we discover that the individual labours under some delusion, it is our duty to consider how far this may prospectively endanger the well-being of himself and his friends. Unless the delusion be such as to render it probable that his own interests or those of others may be damaged by his insane conduct, careful and judicious superintendence will answer all the purposes of the closest restraint. (For some remarks on this subject, see Med. Gaz. xliv. p. 1061.) Some have justified the act of resorting to restraint on all occasions, on the principle that it may tend to the cure of a patient by removing the delusion. In this point of view the subject has no relation to legal medicine. It may be urged with more plausibility, that, by withholding restraint in incipient cases, mischief may be done by the lunatic to himself or others, and that then it will be too late to interfere; but even here proper superintendence will render close confinement unnecessary. A medical practitioner must not be too ready to lend himself to the signing of certificates for the confinement of persons who may be labouring under harmless delusions. In violent mania, or in monomania with a homicidal or a suicidal propensity, there can be no doubt of the propriety of applying some degree of restraint, for here the necessity is imminent. If a remarkable change has suddenly taken place in the character of a patient; if he has become irritable, outrageous, or threatened personal violence to any one, or if he has
recklessly endangered the interests of himself and family, he is undoubtedly a fit subject for restraint. (See Pagan, 75.) The more he approaches to this condition, the less difficulty we shall have in coming to a decision, and in a really doubtful insane there will be no impropriety in employing restraint; s. t., although the person is thereby deprived of liberty, it is better that this should happen, than that he or his friends should incur the risk of suffering severely by his insane conduct.

The forcible removal of a person from his home to a lunatic asylum, unless the circumstances are of such a nature as to render immediate interference necessary on the ground of admitted or proved insanity, is unjustifiable in law, and may involve those concerned in the removal in a serious responsibility. The case of Nottidge v. Ripley (1849) is in this respect of some interest. A young lady of fortune was here clandestinely and violently removed from a place to which she had voluntarily retired; examined by two medical witnesses nominated by those who had forcibly removed her; and then closely confined in a lunatic asylum for seventeen months, without being allowed to communicate in any way with those members of her family who alleged that she was not insane, and who through these tortuous proceedings were unable to discover the retreat of their relative, and to have the case publicly investigated. At the trial for this abduction, the jury returned a verdict against those who were charged with the offence (Med. Gaz. xlv. p. 974). The allegation of insanity was denied, although it was proved that the plaintiff had fallen into the hands of persons whose object was obviously to possess themselves of her property, and that, like her sisters, she had adopted some absurd and pseudo-religious notions. If, however, such violent measures were sanctioned before any preliminary inquiry, medical or otherwise, were instituted into the state of a person’s mind, and upon the mere opinion of non-medical persons or interested relatives, no individual, whether sane or insane, could be assured of his liberty. This case has called forth some criticisms which the reader will do well to peruse. (See Journ. Psychol. Med. 1849, p. 564; and 1850, p. 14.)

In the case of Hill v. Philp (Exchequer, Feb. 1852), an action was brought by plaintiff to recover damages for alleged neglect and unskilful treatment on the part of the defendant, while under his care as a lunatic patient. The plaintiff was examined, and he wished to impress the Court that he was then perfectly sane. His cross-examination, however, elicited the belief that “he was descended from Leofric, the wise Earl of Mercia, who was contemporary with Edward the Confessor.” It was also proved that he had called for water from Jerusalem and the Jordan! In short, there was abundant evidence of insanity, and the jury returned a verdict for the defendant. The case, however, conveys
RULES REGARDING THE CONFINEMENT OF LUNATICS. 881

an important caution that medical men should be careful in the imposition of restraint, as from the evidence it appeared that unnecessary violence had been used on this occasion. There is another circumstance which renders this case of importance to medical practitioners: it involved the question whether in the treatment of a lunatic, a medical man can justify the imposition of restraint by the allegation that he acted under the directions of, or upon the request of, the wife or other relative, at whose instigation the lunatic may have been confined. In Hill v. Philp, the judges decided that a medical man, under such circumstances, may act upon the directions of a wife, but that the directions must only be considered as guiding his judgment, and not as absolutely dictating to him and justifying his proceedings; that he is still bound to exercise his own discretion so far as to refrain from doing anything, or adopting any course, which might be injurious to the patient. A medical man is, therefore, ultimately responsible for his treatment of a lunatic. No person can give him authority to do that which is not in accordance with general practice or the necessity of the case. (For a report of this case, and some judicial remarks upon the decision, see the Legal Examiner, May 29, 1852, pp. 307, 318.)

In order to provide for the protection of lunatics and the prevention of undue violence or frequency in the application of restraint, the law compels the keepers of asylums to enter in a book a report of each case or of each occasion on which any mechanical restraint is resorted to. An omission to make this entry is a misdemeanor: and at the Maidstone Lent Assizes, 1851, two medical gentlemen were convicted and fined for placing patients under restraint without having made the proper entries required by law (Reg. v. Maddock). See also Med. Gaz. vol. xlvii. p. 556; and a paper on the use and abuse of restraint, Journ. Psychol. Med. 1849, p. 240.

Violence of temper must not be taken as a proof of insanity. A man may have always had a violent temper, subject to occasional fits of aggravation; but this must not be confounded with mental disease. In order to determine whether the acts of a person be due to violent temper or insanity, it will be proper to ascertain what may have been his natural habits. The great feature of insanity is change of character: a man who is really insane is different from what he has previously been; but it may be proved of a violent-tempered man, that he has always been the same. The greatest abuses of the restraint system have been chiefly observed in cases of monomania, where persons have been forcibly imprisoned because they entertained some absurd and harmless delusions, over which they had so great a control as to render it somewhat difficult even for a shrewd and experienced examiner to detect their existence. When, at
last, after many hours' cross-examination, the existence of delusion has been made apparent, the result has been looked upon as furnishing matter for triumph and exultation; but, as Dr. Conolly justly remarks, one point in these cases appears to have been wholly lost sight of, namely,—What possible injury could have resulted to the patient or his friends from the existence of a delusion over which he had such complete control and mastery as to render it a most laborious task to obtain any evidence of its existence? (Indic. of Ins.) It may be freely admitted, that, where delusion on any subject really exists, there is reason to suppose that the mind must be more or less disordered in all its faculties; but such patients require close watching, not a rigorous imprisonment in an asylum. The greatest danger is to be apprehended in all those cases where there is the least power of self-control.

Certificates of insanity. — It will here be necessary to state the circumstances which require the attention of a practitioner when he is called upon to sign a certificate of insanity, whereby a person may be placed in confinement in an asylum. The acts which specially refer to this subject are the 16th and 17th Victoria, c. 96 and 97. These acts, which came into operation on the 1st of November 1853, are a consolidation of the statutes on the regulation of the care and treatment of lunatics. Their provisions are very stringent, both with respect to medical men who sign certificates, and those who keep asylums for the reception of lunatics.

According to s. lxxiv. c. 97, no person (not a pauper) can be received into or detained in any asylum, without an order from some person, and two medical certificates, which must be signed by two physicians, surgeons, or apothecaries, not in partnership or an assistant to the other, and each of whom shall separately from the other have personally examined the person to whom it relates not more than seven clear days previously to the reception of such person into such asylum.

Form of medical certificate in the case of private patients:—

I, the undersigned, being a physician or surgeon or apothecary [here set forth the qualification], and being in actual practice as such, hereby certify that I, on the day of , at [here insert the street and number of the house (if any), or other like particulars], in the county of, &c., separately from any other medical practitioner, personally examined A.B., the person named in the accompanying statement or order, and that the said A.B. is a lunatic [or an idiot, or a person of unsound mind], and a proper person to be taken charge of, and detained under care and treatment, and that I have formed this opinion upon the following grounds, viz.:—

1. Facts indicating insanity observed by myself [here state the facts].
MEDICAL CERTIFICATES OF INSANITY.

2. Other facts (if any) indicating insanity, communicated to me by others [here state the information, and from whom].

(Signed) Name.

Place of abode.

Dated this day of , one thousand eight hundred and

Under s. x. c. 96, no person can be received into any registered hospital or licensed house, or as a single patient, under any certificate which purports to be founded only upon facts communicated by others. A medical certificate may be amended if incorrect or defective.

By s. xiii. c. 96, a medical practitioner who gives false certificates, or any person not being a physician, surgeon, or apothecary, who gives certificates as such, is declared to be guilty of a misdemeanor. For any act done by a regular medical practitioner contrary to any of the provisions of the Act (although not declared to be a misdemeanor) he is subjected for each proved offence to a penalty of twenty pounds. By s. xxxvi. c. 96, the words "physician," "surgeon," or "apothecary," shall respectively mean one duly licensed to practise as such by, or as a member of, some College, University, Company, or Institution, legally constituted and qualified to grant such authority or licence in some part of the United Kingdom, or having been in practice as an apothecary in England or Wales on or before the first day of August, 1815, and being in actual practice as such physician, surgeon, or apothecary." (16 and 17 Vict. cap. 96, s. xxxvi.) Thus the certificates of Irish medical practitioners are now valid for the confinement of lunatics in England, and conversely those of English practitioners are valid for the asylums in Ireland. The former acts limited the certificates of practitioners to the countries in which they were respectively licensed to practise, and, as if to show how long an absurdity in legislation may exercise a pernicious influence, a case in reference to this point was argued before the Court of Common Pleas in June 1834, i.e. eight months after the new acts had come under operation! In ex parte Child a habeas was moved for to bring up the body of a Captain Child, confined as a lunatic in Hayes Park Asylum, Middlesex. In April 1842, Captain Child, then being in Dublin, was confined in an Irish asylum. In October 1851, he was removed to Dr. Conolly's establishment at Hayes Park. It was alleged that he was there confined under certificates granted by two competent medical men, Drs. Cusack and Milton; but these certificates were made in Ireland, and it was contended that neither of the gentlemen who signed them was a licensed physician, surgeon, or apothecary, in England. It was argued that if the certificates had been improperly granted, these gentlemen...
where the examination is made, as well as the residence, of the person examined. In a case before Mr. Justice Coleridge on the alleged lunatic (February 1855) confinement of Greenwood was sought. There appears to have been some gentleman’s state of mind. Two physicians laboured under unsoundness, while that he was mentally sound. The county medical society took an objection that, under the name of the street where the patient was to be mentioned in the medical certificate, the name of the street where the patient was to be mentioned in the medical certificate, and Mr. Greenway was in custody. Coleridge J., in giving judgment, said the certificates that the examination was to be held, but the examiners omitted to mention that Blackburn was a large place. The statute prohibited the reception of certificates according to the form in which the direction of the name of the house in which the examiners were to decide on a formal notice of their decision not being given. The judge directed the insertion of the name of the street where the patient was to be mentioned in the medical certificate, and Mr. Greenway was in custody. Coleridge J., in giving judgment, said the certificates that the examination was to be held, but the examiners omitted to mention that Blackburn was a large place. If it were asked, of what benefit was it to Blackb...
these certificates is required to specify the facts upon which his opinion is formed, and whether such facts are derived from his own observation or from the information of any other person.

The 74th section of cap. 97 provides that in cases of emergency a person (not a pauper) may, under special circumstances (these being stated in the order), be received into a house or hospital upon a certificate signed by one medical practitioner only, provided that within three days two other such certificates be signed by two other medical practitioners not being connected with such house or hospital, upon a like examination. The detaining of a person upon one medical certificate only, beyond the period of three days, without such further certificates, is a misdemeanor in the keeper of the house or hospital. By s. lxvii. c. 97, the certificate of one medical practitioner only, signed according to the above rules, will suffice for a pauper lunatic, provided the party has been previously examined by a justice, clergyman, and overseer, or relieving officer. By s. xii. c. 96, no medical practitioner who is interested in or attends a licensed house or hospital, or whose father, brother, son, partner, or assistant, is wholly or partly the proprietor of, or a regular professional attendant in, such house or hospital, shall sign any certificate for the reception of a patient into it. It is obvious from the terms of the act, that one person cannot sign a certificate as a substitute for another, and yet there have been several instances of its violation under these circumstances. In December 1855, a medical assistant was committed for trial because he had signed the name of the surgeon with whom he was living, to a certificate of insanity for the confinement of a pauper lunatic. There was no doubt about the insanity of the person, and the plea urged in defence was, that the surgeon whose name was thus forged was in ill-health and had given the assistant an authority to sign papers for him. This, however, was no justification of a violation of the terms of the act. The words of the certificate are so explicit on this point, that no reasonable person can have any doubt about their meaning.

As ignorance of the law is not allowed to be an excuse for its violation, so a medical man, unless acquainted with all the particulars above mentioned, may easily subject himself to a prosecution; and he is not likely to be spared the disgrace and mortification attendant upon this, should it happen that the case is of a doubtful nature. The law expressly requires from each medical man a separate visit, a separate personal examination of the alleged lunatic, and a separate medical certificate setting forth the special fact or facts, whether observed by himself or derived from the information of others, upon which his opinion is based.

*Specification of facts.* — Medical practitioners have had some difficulty in assigning the fact or facts upon which their judgment of the insanity of a party was based. (Med. Gaz. xxxvi. 1434. •
and xxxvii. 485.) What will constitute the description of a fact to render the certificate valid? This important question was raised and decided in the case of Shuttleworth (Queen's Bench, Nov. 17, 1847). An application was made for the discharge of a lunatic on the ground that the medical certificates did not set forth the facts from which the opinion of those who signed them was derived. In one, it was stated that the lunatic laboured under a variety of delusions, and that she was dirty and indecent in the extreme. In the other the certifier stated that he had formed his opinion from the conversation which he had that day had with her. It was contended that the statement in the first certificate was not so much a fact as a conclusion drawn from other facts which ought to have been mentioned in the certificate itself. Lord Denman, in giving the judgment of the Court, held that the certificates were valid:—that it was not necessary to have all the delusions of an insane person stated in the certificate. The statement that the lunatic was dirty and indecent in the extreme was prima facie sufficient to justify the imputation of insanity, even if the certificate did not state that the patient laboured under a variety of delusions. The allegation that the opinion respecting insanity was founded upon a conversation with the alleged lunatic was also sufficient to render the certificate valid. (Med. Gaz. xxxviii. 932; also Law Times, Nov. 21, 1846, 143.) It will thus be seen that a general statement of the circumstances which have led to the belief of the insanity of a party, will be sufficient compliance with the provisions of the statute to render the certificate valid. In other respects the terms of the certificate are sufficiently explanatory; and any violation of them may subject a practitioner to a trial for a misdemeanor. In June 1848, a surgeon was tried and convicted at the Central Criminal Court of having certified that he had examined a female lunatic on the day on which he put his name to the document, when he had not seen her for two or three months. There was no doubt of the insanity of the party, but as this was an untrue statement, he was convicted of the offence.

Discharge of lunatics. — In forming an opinion relative to the propriety of discharging a person who has once been confined as a lunatic in an asylum, it is proper to examine the particulars of his case with the same caution as if the object were to confine him for the first time. The question of liberation is commonly restricted, like that of restraint, to cases of mania and monomania. It may so happen, that an individual has a lucid interval at the time of examination, in which case it will be necessary to make more than one visit. One who has been guilty of a heinous crime like murder should never, on any pretence, be discharged. There are often long lucid intervals in homicidal mania; and it is impossible to be certain that the disease is entirely removed. If the individual has manifested the least disposition to suicide,
we should be extremely cautious of liberating him; for suicidal mania is often artfully concealed under a cheerful exterior. We cannot always test the propriety of granting liberation by the lightness of the offence for which a criminal lunatic has been confined. The circumstances under which the most trifling offence has been committed, may show that the mind is wholly unsettled with regard to moral responsibility; and such lunatics can never be trusted, even when there is great improvement in their language and deportment. The unhappy result of prematurely discharging a criminal lunatic was seen in the case of a man named Thom, otherwise styling himself Sir William Courtenay. He was shot while rioting with many others near Canterbury in June 1838. The whole life of this man seems to have been made up of a mixture of eccentricity and insanity. He was guilty of the most flagrant perjury, was tried, found insane, and confined as a lunatic. After the lapse of about six months, it was thought that he was so much improved as to allow of his discharge; although, even at this time, it appears that he fancied himself to be the Saviour! On his discharge, he was guilty of many extravagant acts; he collected a number of ignorant persons as his followers, and infected them with his delusion. He resisted the military who were sent to apprehend him, and eleven lives were lost on the occasion. A medical man cannot always be responsible for unfortunate consequences of this kind; but this and other similar instances show that great risk is incurred in hastily allowing the discharge of a lunatic who has once been guilty of a crime, however slight, so palpably depending on a disordered mind. The 16th and 17th of Victoria, c. 97, has placed certain restrictions on the power of liberating lunatics. Under ss. 83 and 84, the person originally signing the order which is required in addition to the medical certificates, may write an order for his discharge or removal; but, under s. 85, this order is of no effect, if a medical practitioner certify that in his opinion such patient is dangerous and unfit to be at large, together with the grounds on which such opinion is founded, unless the commissioners or visitors shall, after the production of such certificate, give their consent in writing for the removal or discharge of such patient. Under other clauses, additional powers of discharge are given to the commissioners and visitors, subject to such restrictions as to leave the control for the most part in the hands of professional men. These powers of discharge do not, however, apply either to criminal lunatics, or to those found insane under a commission issued by the Lord Chancellor.
CHAPTER LXVII.

TESTIMONIAL CAPACITY OF LUNATICS.—INTERDICTION.—COMMISSIONS OF LUNACY.—EXAMINATION OF ALLEGED LUNATICS.—MEDICAL AND LEGAL TESTS OF COMPETENCY.—LUCID INTERVALS.

Testimonial capacity of lunatics.—A question of some importance has arisen regarding the admissibility of the testimony of lunatics concerning facts which they allege they have witnessed. In the case of Reg. v. Hill, tried at the Central Criminal Court in the spring of 1851, the evidence of a man named Donnelly was tendered on the part of the Crown. (Jour. of Psychol. Med. 1851, pp. 279 and 436.) This man was a pauper lunatic, and was confined as such in the same ward with the deceased, who, it was alleged, had been maltreated and killed by the prisoner. It was quite clear from the cross-examination of Donnelly at the trial that he laboured under insane delusions,—that he was constantly visited by spirits, &c.: but, nevertheless, he gave a clear and consistent account of the mode in which deceased was treated by the prisoner, and although he firmly believed in the existence of spirits and their power of communicating with him, he appeared to have a full knowledge of the difference between truth and falsehood. His evidence was received, and upon this the prisoner was convicted. The case was subsequently argued in the Exchequer Chamber before all the judges, and decided in favour of the admissibility of the evidence. It may now, therefore, be considered as settled, that a lunatic who labours under delusions, but who in the judgment of a medical practitioner is capable of giving an account of any transaction that happened before his eyes, and who appears to understand the obligations of an oath, may be called as a witness. (Reg. v. Hill, 2 Denison's Crown Cases, 254.) The rule laid down by Lord Wensleydale is in accordance with this view: it is for the judge to say whether the witness is admissible, and then his credibility is a question for the jury. As old legal dicta on the subject, we find the following:—“An idiot shall not be allowed to give evidence (Co. Litt. b. 6; Gilb. Evidence, 144), nor a lunatic (Ib.) except during a lucid interval” (Archbold, Pleading and Evid. in Crim. Cases, 124); but it is now known and admitted that the shades of insanity are infinite,—that some lunatics are as fully competent to observe and remember facts, and to understand the obligations of an oath, as persons who are sane; hence, therefore, incompetency to give testimony must not be inferred from a mere name assigned to a malady, but it must be decided by the special condition of the lunatic. Under any other view, crimes of the greatest enormity might be perpetrated in lunatic asylums, where the only witnesses
must generally be lunatics, without the possibility of convicting the criminals. It has been appropriately remarked by a good authority, that the fact of incompetence to testify is not necessarily connected with a state of insanity; and it would be far more correct to consider it an independent fact to be established by a distinct order of proofs. The truth is, an analogy in a medico-legal sense has been too hastily assumed between the act of testifying and that of performing business contracts and other civil acts; and, in consequence, it has shared with them in the same sentence of disqualification without an attempt to ascertain the kind and degree of intellectual power which they respectively require. (Ray, Medical Jurisprudence of Insanity; also Medical Gazette, vol. xlvii. p. 150.) In the spring of 1852 I saw Donnelly, the witness in the above case, in the Colney Hatch Lunatic Asylum. His powers of observation and reasoning were very acute and quite sound, except when reference was made to his peculiar delusions regarding spirits. In another case, on appeal at the Middlesex Sessions in December 1852, the testimony of a lunatic was admitted, and he proved the facts of the respondent's case. The resident medical officer testified that the patient had a good memory, and could speak correctly to facts that had occurred before he became insane. In Reg. v. Cogge and others, tried before Lord Campbell at the Nottingham Lent Assizes, 1856, this kind of evidence was received on a trial for felony. The prisoners were charged with highway robbery, and the prosecutor could not clearly speak to their identity. A man named Bourne witnessed the transaction and swore positively to two. Previous to the trial he was attacked with insanity, and was then confined in an asylum. He was produced as a witness, and gave his evidence in a very clear and calm manner. It was received, and upon it chiefly the prisoners were convicted.

Interdiction. Commissions of lunacy.—By interdiction we are to understand the depriving of a person labouring under mental disorder of his civil rights; in other words, preventing him from exercising any control or management over his affairs. It may be with or without restraint, for one condition does not necessarily imply the other. When an individual, from mental incompetency, is liable to be imposed upon by others, or is guilty of foolish and extravagant acts, whereby his property is damaged, a Commission is commonly granted by the Court of Chancery, in order to determine whether he be "compos" or "non compos mentis." This writ is well known under the name of "de lunatico inquisiendo." Before it can be issued, it is necessary, among other matters, that there should be affidavits, made by two or three physicians or surgeons, certifying to the insanity of the party. It has been already explained that the object of the law is to determine whether the incapacity to manage affairs be owing to
some mental defect or disorder, and not merely to want of education or bodily infirmity,—otherwise all wealthy minors and infirm persons might be improperly deprived of the control of their property. It is unfortunate that these commissions have been hitherto conducted on so expensive a scale as to render them applicable only to the wealthy classes of society; and even the expenses attending such a simple inquiry as that for which the commission is issued are often of the most ruinous kind, and the results are by no means satisfactory. (See the cases of Mr. Davies, Miss Bugster (July 1832), of Lady Kirkwall (Feb. 1834), Mrs. Cumming (1846), and others.) When insanity is pleaded in a criminal case, one judge and twelve jurors will decide the question, affecting as it does the life of a party, in a few hours, and at very little expense! It is difficult to understand why, in a question of competency to manage affairs, so many more functionaries should be required, so much more time—sometimes amounting to twelve or fifteen days—occupied, so many witnesses examined, and such enormous expenses should be thereby incurred. The property of tradesmen, and of other persons of small means, is under such a system left unprotected. This expensive process of wasting an alleged lunatic's fortune in order to determine whether he is or is not likely to waste it himself, leads to the result that, compared with the number of lunatics under confinement, the inquiries are very few. Out of 3774 persons confined in 1850 above the pauper class, there were only 238 cases in which inquiries were held; i.e. there is only one lunatic in eleven whose property is thus protected by a commission, apparently because the protection involves a greater waste than if it were left unprotected! (Med. Gaz. vol. xlvi. p. 1023.) By a new regulation the Lord Chancellor has it in his power to direct an inquiry before one or two commissioners, in which case a jury is dispensed with. Evidence may thus be received, and the decision left with one commissioner. In a case of this kind, care should be taken that the alleged lunatic is duly represented. The costs of an inquiry are by this regulation greatly reduced.

One source of difficulty on these occasions is, that medical witnesses are allowed to be summoned by both parties, and the opinions given often exactly neutralise each other; they are hereby converted into partisans and are retained in the cause, as much as if they were counsel. It has been well remarked, that a man, even unknown to himself, with the purest intentions and the most perfect rectitude, will insensibly lean to the side on which he has been consulted. (Pagan, 301.) The public are apt to infer, from such conflicting opinions emanating from men of equal experience, that the difference cannot depend essentially on the medical facts of the case; and that the question might be better determined by non-professional persons. See the case of Carpenter, Dublin Med. Press, July 16, 1845, p. 46; also that
of Mrs. Cumming (1846), in which the conflict of medical testimony was even greater than usual. The inquiry lasted sixteen days, and cost five thousand pounds! In fact a large portion of this lady's property was spent in determining by a verdict that she was insane; and there was an intention that the remainder should be expended in reversing the decision, when the unfortunate lady died! [The reader will find a report of this remarkable case in the Journal of Psychological Medicine for April 1852.] A remedy for this serious evil would be, that medical witnesses on such occasions should be appointed, like the commissioners, by the Chancellor, and they would be thereby made perfectly independent of both parties. At present they rather occupy the position of medical counsel than medical witnesses; for it is quite clear that no one would be summoned by a solicitor whose views did not coincide with those of the party summoning him; and it is an opinion among some solicitors, for which, unfortunately, there is an apparent reason, that medical evidence on these occasions is a marketable commodity, and may be purchased at graduated prices! There are some medical men who appear to think that on these occasions they are justified in sinking the witness in the advocate, and that they are bound by a sort of duty to make the best of the case for the person who retains them; but this is a mistaken view of their position. An advocate is not bound by an oath to state "the truth, the whole truth, and nothing but the truth;" but a scientific witness is placed under this sacred obligation, and it is a duty which he owes to his profession and to society that he should lay aside all personal bias. It may appear a very innocent matter to suppress certain facts and to exaggerate the importance of others, in order to induce a jury to pronounce one whose mental soundness is in question to be perfectly sane and competent: but the same mercenary zeal which would thus lead to the civil freedom of an insane person, might, on another occasion, be employed in unjustly depriving a sane person of his liberty. The confidence of the public in medical opinions is already much shaken; and it would be altogether destroyed and such opinions dispensed with, if it were once known that a medical man on these occasions accepted a retaining fee not to speak the whole truth, but, rightly or wrongly, to give a verdict for the party who consulted him. Whatever may be the nature of the case, experienced solicitors know that if they only search far enough they will generally fall upon some medical witnesses who will adopt their views. (The reader will find some remarks on this subject in the Medical Gazette, vol. v. 719; xi. 740; and xvii. 816.) An improved course of proceeding was adopted in re Taylor (April 1857). This gentleman had been examined by seven medical men, three of whom pronounced him to be of unsound mind, and four declared him to be perfectly sane, but with an
impaired memory. There was here a majority of one in favor of sanity. The Lords Justices, on this, deputed Dr. F. Winslow to examine and report on the condition of the lunatic for their special information. He reported in favor of soundness of mind, admitting the existence of defective memory, partly arising from age. The decision of the Court was in accordance with this view.

The law of Scotland has, in this respect, the advantage of that of England in simplicity and justice. A factor is appointed, on the application of relatives, to take charge of the property. Notice is given to the alleged lunatic, so that he may, if he pleases, oppose the appointment. Medical evidence is received, and upon this the decision of the Court is chiefly based. The appointment, if made, can at any time be revoked upon good and satisfactory grounds.

Examination of alleged lunatics — To determine whether a person is or is not a fit subject for interdiction, it is necessary to bear in mind that it is not enough to show there is delusion, as in the lighter cases of monomania, but we are bound to determine how far the delusion affects the judgment of the party, so as to prevent him, like other men, from managing his affairs with prudence, care and propriety. In many instances, however, some proof of delusion only is sought for; and if this be procured, it is somewhat hastily inferred that the party must be entirely incompetent to the management of his property. The most difficult cases are those involving questions of imbecility. In conducting the examination of an alleged lunatic, we should compare his mind as it is with what it has been; and if it be a case of supposed imbecility, a proper regard must be had to age, society, education, and general conduct. We should also consider whether the person has been treated by his friends and relations as a lunatic or imbecile prior to the issuing of the commission. A young person whose education has been much neglected, and who has never been intrusted with the care of money, cannot be expected to have much knowledge of the method of managing a large property. Questions are sometimes put on the moral responsibility of man and the attributes of God to one who, perhaps, never heard of metaphysics. Arithmetical questions are asked which would embarrass many persons who are set down as sane and competent. In a case which occurred a few years since, one examiner asked the alleged imbecile, who said he had £1,200 in the Bank, and received £20 for interest,—How much was that per cent? He said “he could not tell; he was no good hand at arithmetic.” The counsel who appeared against the brief or commission afterwards put the same arithmetical question to one of the medical witnesses who had deposed to the imbecility of the party; and this witness, an educated man, confessed himself unable to answer it—a practical illustration of the impropriety of pronouncing a person to be imbecile merely because he is
ignorant of that which he has never been taught! (Case of David Yoolow, 1837.) If the capacity to manage affairs rested solely upon a knowledge of arithmetic, many now go free who ought to be immediately placed under interdiction. This is rather a commercial test of insanity: but it will be found that it has been applied in a very improper manner to determine the capacity of young and ill-educated females. Unless the questions be confined to those subjects which the party has had either the opportunity or inclination to learn, a medical witness will always incur the risk of confounding mere ignorance with imbecility. Perhaps one of the best tests of mental capacity will be found in determining the degree to which, with ordinary opportunities, the person has shown himself capable of being instructed. Too high a standard must not be assumed as a test for capacity. The mind of an alleged imbecile should not be compared with the most perfect mind, but with that of another person of average capacity, of the same age and station in society, and who has enjoyed like opportunities of instruction. A defective memory must not be hastily set down as a proof of legal unsoundness. In a case which came before the Lords Justices Bruce and Turner in August 1855 (Re Toplis), the petitioners for a commission appear to have relied chiefly on a defect of memory in a person who was advanced in life. The Lords Justices, in dismissing the petition with costs, made the following observations:—"Mr. Toplis's powers of recollection were impaired and defective, but this at advanced periods of life, and also at periods not advanced, was a common defect. A man might have a bad memory, but be a competent and efficient man, and no man would venture to suggest that a person could not discharge the business of life because he had a bad memory. The memory, indeed, might be so deficient as to bring a man within the technical description of unsound mind, but it could not be suggested that that was the case with Mr. Toplis. He appeared to recollect the events of his early life with readiness and freshness, and the more recent the event was, the sooner it faded from his memory; but, bad as his memory might be, he had more than sufficient mind, within the meaning material for all present purposes, to say that he was perfectly well able to manage himself and his affairs. Dr. Southey, who had been deputed by them to examine Mr. Toplis, made use of the following expressions in his report: "With a memory so deficient, it can hardly be said Mr. Toplis is of perfectly sound mind." In one sense this might be true, but, as their lordships observed, there was a technical meaning of these words, in reference to which they dissented from their use. A man may not have a perfectly sound mind, and yet have a mind sound enough for the management of his affairs. A defective memory in an aged person, taken alone, proves nothing. (See Ann. d'Hyg. 1836, i. 192.)
A medical witness must not allow himself to be embarrassed by medical or legal definitions of insanity. The malady may not have the form of lunacy or idiocy in a strictly legal view; nor of mania, monomania, dementia, or idiocy, in a strictly medical view; but still it may be a case of such mental disorder as to create an incapacity for managing affairs. This is the point to which a medical examiner has to direct his attention. Cases of imbecility present the greatest difficulty, and create the greatest conflict among medical opinions. Imbecility strictly implies a weak or feeble mind, and the term is properly applied to one who has an intellect below par or below the normal average. The vagueness of these terms shows how difficult it is to draw a clear distinction, between legal sanity and that degree of mental weakness implied by imbecility, which would justify interdiction. Insanity in the common acceptance of the term cannot be proved in these cases: there will be no evidence of delusion, there may be such an amount of self-control as to enable a person to maintain a conversation. Memory, judgment, and other faculties, although weak, are still present in greater or less degree; and from one or two interviews only, an examiner might be disposed to pronounce the person of sound mind and competent to manage his own affairs. There is a wide field for argument here; for it may be said with some truth, in a defence, “that the doctors cannot put their finger on a single point indicative of insanity.” In short, each fact specified by them may be frittered away by the remark that every one must have known some person who had either a bad memory, or a weak judgment; who squandered money, who wasted it on unworthy objects, who hoarded it and refused to pay just debts, or who lost it in foolish speculations, &c. All this may be true, and yet the person in question may be legally of unsound mind and properly interdicted. As Dr. Pagan justly remarks, there is a facility of disposition in an imbecile or weak-minded person, which lays him open to be imposed upon by the artful and designing; and our conclusion regarding his competency must be the result of a just appreciation of his general knowledge of affairs, and by an examination of all his faculties. We have to consider how far his imperfect faculties would prevent him from attending to his own interests, not in a manner which would insure their most profitable application, but in such a way as would prevent him from being involved in ruin. The test is, that his knowledge and understanding are so imperfect that his property would necessarily run to waste under his unassisted control. When it is proved that there has been habitual submission to the dictation of others, either from long habit of being controlled, indifference, or fear, this is in itself a proof of weakness of mind, and a justification of the opinion that there should be interdiction. (Op. cit. 293.) On the other hand, if a person when left to himself has managed his
affairs with reasonable care, and has acted independently of others, there can be no stronger proof of legal competency.

The testamentary capacity of imbeciles may be tried by the same rules. A man who is of such easy disposition as to be improperly influenced in the use of his property while living, may be equally influenced by fear or control to make an improper disposition of it in his will; but in this case the terms of the deed will allow a fair judgment to be formed of the mental soundness of the testator. Dr. Conolly has suggested one method of testing the state of mind, which it would be advisable to adopt, namely, to cause the individual to express his thoughts in writing. He would not here be led to suspect that he was being subjected to an examination for a hostile purpose. In many cases, the evidence of a strong delusion existing in the mind has been derived from a will, deed, or letters written spontaneously by the lunatic or imbecile, when there was considerable difficulty in obtaining this proof by a verbal examination.

Among many cases which might be here cited to illustrate the medical evidence required and received on commissions of lunacy, one may be selected which excited much interest at the time of its occurrence: I allude to that of Miss Bagster, which underwent inquiry in July 1832. It will serve to show upon what slight grounds a verdict of "unsound mind" may be returned under a commission of lunacy. The subject of this inquiry was shown by the evidence to be a frivolous and weak-minded girl, whose education had been much neglected. She was heiress to a large fortune, and contracted a clandestine marriage unsuited to her condition. A commission was taken out by her friends for the purpose of annulling her marriage, by showing that she was not at the time competent to give rational consent. The general evidence established that there had been great neglect in her education, and that she had been especially indulged; but it did not appear that she had ever been treated by her friends as of unsound mind, nor, indeed, that any question of her insanity had been raised, until after her marriage. Seven medical witnesses, summoned to support the commission, deposed that she was of unsound mind. On the other side no witnesses were called, as it was considered that the allegation of insanity was not made out. The Commissioners, however, themselves, called Dr. Morrison and Dr. Haslam, who deposed that her incompetency to manage her affairs arose, not from unsoundness of mind, but from ignorance. She gave one strong proof of her sanity, namely, that she was aware of and admitted her deficiencies. It seems to have been allowed that she was capable of controlling herself, and concealing her defects; her answers to the questions put to her were pertinent, and were for the most part correctly made, and she had capacity to receive instruction. She was ignorant of arithmetic, but this she had never been properly taught.
She was young and inexperienced, and therefore unable to answer questions relative to the management of a household. The jury, by a majority of twenty to two, returned a verdict that she was of unsound mind, and had been so for the space of two years—time which covered the marriage. (See Med. Gaz. vol. x. p. 519, et seq.) It is worthy of remark, that the two medical witnesses (independent of both sides) who were summoned by the Commissioners gave a very strong opinion that Miss Bagster was ignorant, and not of unsound mind; and that she might, by instruction, be rendered competent to the management of her affairs. We should imagine that where the question arose whether a young person was or was not to be deprived of all civil rights, there ought to be at least unanimity among the medical opinions, or, if this were denied, then more weight should be given to the negative than to the affirmative side of the question, providing if, as in this case, the negative view were supported by men impartially selected, and of great experience and knowledge on the subject of insanity. It is not improbable that, beside ignorance, there may have been some degree of weakness of mind about this person; yet, taking the whole case, we must attribute the verdict of unsoundness, not so much to mental infirmity as to incapacity, for want of instruction, to manage a large fortune. But if every wealthy young lady, whose education had been much neglected, had her sanity tested on the same points as Miss Bagster, it is certain that many who are now free agents would be placed under interdiction! It has been attempted to justify the verdict by the statement, that it saved her from the results of an imprudent marriage,—the answer to which is, that commissions of lunacy are not intended to shield persons whose minds are not really unsound, from the results of foolish and imprudent acts.

Commissions may be superseded, but the evidence in such a case must be as strongly in favour of sanity as it was before in favour of insanity. In Dyce Sombre's case, July 1844, the physicians of England and France came to directly opposite conclusions, and English physicians were equally arrayed against each other! (See the judgment of the Lord-Chancellor, as reported in the Law Times, Sept. 28, 1844; also a notice of a treatise on his own case and the law of lunacy, by Mr. Dyce Sombre, in the Journ. Psychol. Med. 1850, p. 409.) There have been few cases in which so great a difference of opinion has existed among medical witnesses as in this. Five English medical practitioners of good standing were, however, in favour of his sanity. The decision was against superseding the Commission, chiefly on the ground of the existence of delusion: but the most extraordinary part of the case was, that the alleged lunatic was allowed to have the uncontrolled use of a large portion of his property! (Med. Gaz. xl. 893.) In 1851, arrangements were made for an inde-
Lucid Intervals in Cases of Insanity.

Pendent medical Commission, to inquire into the mental state of this gentleman, and, if possible, to reconcile the conflicting medical opinions already given; but before this was constituted, the alleged lunatic died. (For some remarks on this case, see a letter by Dr. Mayo, Med. Gaz. xlvi. p. 123; also Medical Testimony, p. 31.) It has been suggested by Dr. Chevers that many of the acts which were considered to indicate insanity in this case might be traced to Oriental habits and prejudices. (Med. Jur. for India, p. 574.)

Lucid intervals.—By a lucid interval, we are to understand a temporary cessation of the insanity, or a perfect restoration to reason. This state differs entirely from a remission, in which there is a mere abatement of the symptoms. It has been said that a lucid interval is only a more perfect remission; and that although the lunatic may act rationally and talk coherently, yet his brain is in an excitable state; and he labours under a greater disposition to a fresh attack of insanity than one whose mind has never been affected. Of this there can be no doubt; but the same reasoning would tend to show that insanity is never cured; for the predisposition to an attack is undoubtedly greater in a recovered lunatic than in one who is and has always been perfectly sane. Even admitting the correctness of this reasoning, it cannot be denied that lunatics do occasionally recover for a longer or shorter period, to such a degree as to render them perfectly conscious of, and legally responsible for, their acts like other persons. The law intends no more than this by a lucid interval: it does not require proof that the cure is so complete that even the predisposition to the disease should be entirely extirpated. Such proof, if it could even be procured, would be totally irrelevant. If a man acts rationally and talks coherently, we can have no better proof of a restoration to reason. If no delusion affecting his conduct remain in his mind, we need not concern ourselves about the degree of latent predisposition to a fresh attack, which may still exist.

Lucid intervals sometimes appear suddenly in the insane. The person feels as if awakened from a dream, and there is often a perfect consciousness of the absurdity of the delusion under which he was previously labouring. The duration of the interval is uncertain; it may last for a few minutes only, or may be protracted for days, weeks, months, and even years. In a medico-legal view, its alleged existence must always be looked upon with suspicion and doubt when the interval is very short. These lucid intervals are most frequently seen in cases of mania and monomania; they occasionally exist in dementia, when this state is not chronic, but has succeeded a fit of intermittent or periodical mania. They are never met with in cases of idiocy and imbecility. It is sometimes a matter of great importance to be able to show whether or not there exists, or has existed, a lucid.
interval; since, under these circumstances, the act of the person are deemed valid in law. The mind should be tested in determining whether the patient be labouring under mania or not. He should be able to describe his feelings, and to the subject of his delusion, without betraying any signs of necessary vehemence or excitement. It may happen that a person who is the subject of a commission of inquiry at the time of examination, under a lucid interval, in which case there may be some difficulty in forming an opinion as to the extent of insanity. This occurred in the case of Lady Seymore (July 1835), when examined before a commission, her replies were sudden and collected, that no verdict could be given, and the case was adjourned. When the inquiry was resumed, it was established that she was insane, not merely by general and medical evidence, but by the terms of her will which had been drawn up by herself. The same circumstance happened in the case of Mrs. Hartley and Mr. Pearce, who were the subjects of commissions in 1843. It has been said that a person in a lucid interval is held by law to be responsible for his acts, whether these be of a civil or criminal nature. In regard to offences committed during a lucid interval, it is the opinion of some medical jurists that no person should be convicted such circumstances, because there is a probability that before the time have been under the influence of that degree of cerebral irritation that renders a man insane. (Pichard.) This remark applies especially to those instances in which the lucid interval is very short. Juries now very seldom convict, however, in appearance a crime may have been perpetrated when it is clearly proved that the accused was really insane with a short period of the time of its perpetration.

CHAPTER LXVIII.

RESPONSIBILITY IN CIVIL CASES.—INSANITY AS AN IMPEDIMENT TO MARRIAGE.—DEEDS AND CONTRACTS.—WILLS MADE IN INSANITY—TESTAMENTARY CAPACITY—TEST OF CAPACITY—ELUSION IN THE DEED—ECCENTRICITY IN WILLS—WILLS IN SENILE DEMENTIA—WILLS IN EXTREMIS.—RESTRICTION OF MEDICAL OPINIONS.

RESPONSIBILITY IN CIVIL CASES.

Insanity as an impediment to marriage.—Insanity is deemed by law to be a civil impediment to marriage, because it is considered that there cannot be that rational consent which is necessary in
the validity of a contract. The marriage of a lunatic is therefore called a nullity, and is void ab initio. All that the law requires is, that there should be good proof of insanity at or about the time of the contract. If this be offered, and it be alleged that the contract was entered into during a lucid interval, then the party who would benefit by the allegation must prove it. The suitableness of the marriage, as well as the conduct of the party during or after its performance, will also be considered by the Court. In the case of Turner v. Myers, a lunatic who had recovered from his lunacy instituted a suit to set aside a marriage which he had contracted while in that state. The marriage was declared void. (Med. Gaz. viii. 481.) The case of Bakty v. Ellis (Norwich Summer Ass. 1851) will be found of interest in relation to the matrimonial engagements of alleged lunatics.

In the case of Read v. Legard, (Court of Exchequer, May 30, 1851,) a question arose whether a lunatic was responsible for necessaries supplied to the wife. The articles supplied were for the sole use of the wife, the husband being a confirmed lunatic and the inmate of an asylum. The Court held that the fact of a husband being from the visitation of God unable to manage his affairs, did not absolve him from the obligation which he contracted when he married, to provide necessaries for the support of his wife. He was then of sane mind, and although he had subsequently become insane, that obligation was not revocable under the circumstances. (See also a report of the case of Seaton v. Adcock, Journ. Psychol. Med. 1851, p. 297.)

The validity of civil contracts entered into by lunatics, will depend mainly on the circumstances which accompany the act. If there be nothing unreasonable in the conduct of the lunatic, and the party with whom he contracts has no knowledge or suspicion of the insanity, then the contract will be binding on the lunatic and his representatives. It was so held in the case of Moulton v. Cumeroux (Exchequer, June 1848). This was an action by the administrator of a deceased person, to recover from the defendant, as secretary of an insurance office, the sum paid by him as the consideration for two annuities, the foundation of the action being, that, at the time of the arrangement in question, the deceased was not in a sound state of mind. At the trial before the Chief Baron it appeared that the negotiation had been conducted by the deceased with apparent prudence, sanity, and judgment, and that the arrangement entered into by him with the office was just such as any ordinarily prudent person would have been expected to make with a view to his own interest. The deceased, who died very soon after the business had been arranged, was, both before and after, in an unsound state of mind. Under these circumstances, this action was brought by his representatives, and a verdict recovered by them, subject to the opinion of the Court on their right to recover as on the
entire failure of consideration. The Chief Baron, in giving judgment in favour of the defendant, said it was sufficient for the purpose of this case to lay it down as a general rule, that when a person of apparently sound intellect enters into a contract such as any other ordinary person would enter into with others who act bona fide, and the parties cannot be restored to their former condition, it is no ground for setting aside the contract, that one of them was at the time non compos mentis. On appeal to the Exchequer Chamber this judgment was affirmed in May 1849. (See also the case of Staniland v. Willett, Vice-Chancellor's Court, Nov. 1848.) In the case of Donat v. Homersham (Guildhall Sittings, 1854), on an action to recover a sum of money in which the defence was that the defendant was of unsound mind at the time of the contract, Crompton J. held that unless it was shown that the plaintiff had taken advantage of defendant's unsoundness of mind he would be entitled to recover the amount claimed.

Wills made by the insane. Testamentary capacity.—Questions involving the testamentary capacity of individuals are of very frequent occurrence, and medical evidence is commonly demanded. When property is bequeathed by a testator out of the usual order of succession, it may be alleged by the relatives that he was wholly incompetent to understand the nature of the deed—either from actual insanity, the imbecility of age, or that natural failing of the mind which is so often observed to occur on the approach of death. Bodily disease or incapacity does not affect the validity of a will, unless the mind be directly or indirectly disturbed by it. Some time since a case occurred in France, in which a will was contested on the ground that the testator, when he executed it, was labouring under hemiplegia. The opinion of Esquirol was demanded, and he said that hemiplegia might undoubtedly affect the brain, a fact clearly indicated by the sight, hearing, and other senses becoming weakened; yet this, in his opinion, did not necessarily indicate an impairment of the understanding. (Ann. d'Hyg. 1832, i. 203.) A man's mind, under these circumstances, may not be so strong as in robust health, but still it may retain a disposing power. In the case of Harwood v. Baker, decided by the Privy Council in 1841, a will was pronounced to be invalid, owing to the general state of bodily disease in which the testator was at the time of making it. It appears that he was labouring under erysipelas and fever, and these diseases had produced a degree of drowsiness and stupor which rendered him incompetent to the act. In the case of Day (June 1835), epilepsy was alleged to have affected the mind; and in the case of Blecwitt (March 1833), paralysis was adduced as a ground of incompetency. In all cases of this kind, the law looks exclusively to the actual effect of the bodily disease upon the mind; and this is commonly a purely medical question. In the case of
Penfold v. Crawford (C. P. Dec. 1843), it was shown that the testator had lost his speech from an attack of apoplexy; but it was proved by medical evidence that his mental powers were good, and therefore a deed made subsequently to the attack was held to be valid. In the case of Whyddon v. Billinghurst (Prerog. Court, July 1850), a will was set aside because it was executed by the testatrix while labouring under an attack of cholera in Sept. 1849, and proper means had not been taken to test the capacity of the deceased, who, at the time of its execution, was reduced to an extreme state of weakness. *Integritas mentis non corporis sanitas exigenda est.*

The case of the Duchess of Manchester (the Duke of Manchester v. Bennett, Kingston Lent Assizes, 1854) is of importance in relation to this branch of medical evidence. The Duchess had made a will, which was disputed on the ground that, from bodily illness and mental incapacity, she was not at the time competent to dispose of her property. In 1843 she had made a will bequeathing her property to her children. In 1848 she made another will revoking that of 1843, and bequeathing the absolute control of her property to her husband the Duke. This second will, which was executed on or about the 26th October 1848, was the subject of dispute. It appeared from the evidence that the Duchess had been seized with hysteria and strong convulsions on the 12th of September preceding, but her mind was not then affected. On the 1st October she was again attacked with convulsions, and, according to some of the witnesses, she laboured under acute mania, with symptoms of inflammation of the brain. She died on the 21st November, about three weeks after the execution of the will; and there was evidence to show that she had had some delusions both before and after its execution. A physician who was the medical attendant of the family, and who was one of the witnesses to the will, deposed that on the day it was signed, and for some days previously, the Duchess had recovered her reason, and that, at the time of signing it, she was in his judgment aware of what she was doing, and that she voluntarily delivered it as her own act and deed. It appeared also, that the disputed will was substantially such as the Duchess had announced her intention to make long before and after its execution, and when it was not suggested that she was in an unsound or incompetent state of mind. Three medical men of eminence were called on the part of the defendants; and they expressed their opinions, from the evidence, that the deceased, at the time of making the will, was incompetent to make it; that, in fact, she was proved to have been insane, and there was no medical evidence that she had had a lucid interval. These opinions were based on the nature of the illness, its duration, and the probability (for there was a want of any direct evidence on this point except that which showed the Duchess to be in a sane and dis-
posing state of mind) that this illness still affected her mind when she executed the will. The point at issue, then, was—Was she, or was she not, in a competent state of mind at the time of executing the will? The jury found that she was competent and that the will was valid; but a new trial was subsequently granted by the Vice-Chancellor, although the matter was ultimately arranged without it.

It is to be regretted that the rule given at p. 907 for testing the capacity of the testatrix was not adopted by the medical attendant before he attested the will of the Duchess. Had he applied this rule, there can be no doubt that the whole of the painful litigation which followed would have been avoided. Nevertheless, the evidence for the plaintiff, assuming the statements of the medical gentlemen who attended the Duchess to be true, appears to me to show that, when the will was executed, the Duchess had a disposing capacity.

The great point at issue in the case was purely of a medical nature; namely, whether the delusions or wanderings under which the Duchess laboured during her illness were the real delusions of insanity—fixed mental derangement (mania), or only the temporary delusions of delirium—the result of the disease under which she was labouring. In granting a new trial, the Vice-Chancellor very properly stated, that, in reference to permanent proper insanity, there was great difficulty in proving a lucid interval. A patient so affected is not unfrequently rational to all outward appearance, without any real abatement of the malady; so that, in truth and substance, he is just as insane; his apparently rational, as in his visible raving, fits. But the apparently rational intervals of persons merely delirious are not the most part really such. Delirium is a fluctuating state of mind created by temporary excitement, in the absence of which to be ascertained by the appearance and conduct of the patient, the patient is most commonly really sane. Further, in cases of permanent or fixed insanity, the burden of proof lay on the person setting up the instrument; and the presence or absence of delusions ought to be tested at the time by indisputable evidence that on the subject in question delusion is absent from the mind. If the delusions arise from delirium, the onus of proof would not be on the party setting up the instrument.

There probably never was a case in which the necessity of drawing a clear distinction between mania in its acute form, and delirium dependent on disease, was more strongly manifested than in this. The medical facts for the basis of an opinion were really very few and simple, and they appear to me to lead to only one conclusion, i.e. that the occasional wanderings or delusions of the Duchess were the results of delirium from bodily disease, and not of permanent insanity—that this state is quite compatible with the existence of intervals of perfect competency.
—and that the conduct of the Duchess, at the time of executing the will, was such as to show that she had a full knowledge of the nature of the act which she was performing. I draw this conclusion from an examination of authentic notes of evidence given at the trial.

Test of capacity.—A person is considered to be of a sane and disposing mind who knows the nature of the act which he is performing, and is fully aware of its consequences. From some decisions that have been made, it would appear that a state of mind for which a party might be placed under interdiction would not render him incompetent to the making of a will. The validity of the will of a lunatic was once allowed, although made while he was actually confined in an asylum, because the act was rational, and it was such as the lunatic, some years prior to the attack of insanity, announced his intention of making. (Coghlan's case; see also, Re Garden, Law Times, July 6, 1844, p. 258; also the case of Carterwright. Mayo on Medical Testimony, p. 44.) The insanity of a party, when not already found insane under a commission, must not, in these cases, rest upon presumption, but be established by positive proof. The commission of suicide is often hastily assumed to be evidence of insanity; but it would not be allowed as a proof of this state, even when a testator destroyed himself shortly after the execution of the will. A case has been decided, where the testator committed suicide three days after having given instructions for his will; but the act was not admitted as a proof or even as a presumption of insanity, and the will was pronounced to be valid. A case has been decided on similar grounds in the French courts. In the case of Edwards v. Edwards (Prerog. Court, Feb. 1854), it was proved that the testator had committed suicide three days after the execution of his will, and there was some evidence of eccentric habits almost amounting to insanity; but the will was pronounced to be valid.

As we shall see hereafter, suicide is not deemed in law to be a proof of the existence of insanity.

Delusion in the deed.—The validity of deeds executed by persons affected with monomania, is often a subject of dispute. The practice of the law here indicates that the mere existence of a delusion in the mind of a person does not necessarily vitiate a deed, unless the delusion form the groundwork of it, or unless the most decisive evidence be given that, at the time of executing the deed, the testator's mind was influenced by it. Strong evidence is often derivable from the act itself, especially where a testator has drawn it up of his own accord. In the case of Barton (July 1840), the Ecclesiastical Court was chiefly guided in its decision by the nature of the instrument. The testator, it appeared, laboured under the extraordinary delusion that he could dispose of his own property to himself, and make himself his own legatee and executor! This he had accordingly done. The instrument

3 x 4
was pronounced to be invalid. But a will may be unjust to the surviving relatives of a testator, and it may be some of the extraordinary opinions of the individual, not necessarily be void, unless the testamentary deposition clearly indicate that they have been formed under the influence of a delusion. Some injustice may possibly be done by the adoption of this principle, since delusion may certainly be a man’s act, whether civil or criminal without our being able to discover it; but, after all, it is perhaps the most rational way of construing the last wishes of the dead. According to Sir John Nichol it is not necessary in civil suits to connect the last act with itself; if the mind in which the act is void. In the case of Roberts v. Kerslake (Norte. Auct. Assizes, 1834) Lord Wensleydale held that it was to be inferred if it be a case of delirium the act must be traced to insane delusion; but if it be a case of lunacy it need not be so.

In Sharpe v. Macaulay (Winchester 12th June 1836) Martin B. advised the jury in coming to a conclusion the question at issue, whether the testator had a “sanctified disposing mind,” to look, not to the opinions of others, but to the man’s own acts as well as his correspondence. A disposition implied that a man understood the nature of his property and benefits arising from it, and sense and discretion to persons to enjoy his property after his death.

Eccentricity in wills.—The evidence in these cases sometimes amounts to proof of eccentricity only on the part of the testator, or in the deed itself; but a clear distinction must be here drawn. The will of an eccentric man is such as would always have been expected from him; the will of one having under insanity (delusion) is different from that which he would have made in an unaffected state; — the instrument is still different from what it would once have been. It has been truly observed, that the insane are eccentric in their ideas, their language, or their conduct; but the merely eccentric have not a voluntary resemblance to the insane. (Jamieson’s Lectures, Nat. Gaz. xlvi. p. 180.) In the case of a Mr. Stott, a medical electrician, whose will was disputed by his daughter on the ground of insanity, it was proved that the testator fancied he could draw pregnant women by means of electricity, and he actually proposed to the wife of a baker living in the neighbourhood, to brag about her accouchement by an electrical machine! The will was pronounced invalid, not so much on account of this extreme absurdity, as of the violent and unnatural treatment to which he had subjected his daughter. It appeared that he had taken, as we now and then find in monomanias, a most unaccountable and causeless dislike to this girl from her earliest infancy. Strange as it may appear, electricity has been lately used as a means of aiding parturition, but under circumstances very different from
MORAL INSANITY IN RELATION TO WILLS.

those which gave rise to the absurd delusion in the case just related. (Med. Gaz. xxxvi. p. 376.) It has become a grave question, whether proof of moral insanity; i.e. a perverted state of the moral feelings or affections, independently of any direct evidence of intellectual disturbance, should be a sufficient ground to set aside the act of a testator. In the case of Frere v. Peacoche (Prerogative Court, Oct. 1845), this was the principal question at issue. The counsel who maintained the validity of the will argued against the admissibility of Pinel’s doctrine of moral insanity, chiefly because there was a difference of opinion among those who adopted the doctrine, whether it was or was not invariably accompanied by some mental derangement. A doctrine thus novel, unsettled, and not sufficiently developed could not, it was urged, be safely applied to legal questions. If a man who was free from delusions (as the deceased in this case was), and capable of acts of business (as he was), might nevertheless be held to have been insane, it would involve this branch of testamentary law in utter confusion. A man who was not a subject for a commission of lunacy might be held after death to have been morally insane. The Court would have to deal with cases of kleptomania and pyromania, in which the individuals exhibited no trace of intellectual insanity or delusion of mind. It was safer to rely upon the ancient and general doctrine of these Courts, that there was no insanity without delusion,—its true criterion; and that in the present case the deceased, though eccentric, was not of unsound mind. The Court found that the will was valid, and that there was no proof of delusion. The deceased was a most unamiable being; but still his acts were not irrational, nor inconsistent with soundness of mind. (Prerog. Court, Aug. 1846.) In no case, probably, has eccentricity come so near to insanity as in this.

Wills are sometimes contested more on the ground of eccentricity than of insane delusion; but, if eccentricity only be proved, a Court will not interfere. In the case of Morgan v. Boys (1838), it was proved that the testator, by his will, had left a large fortune to his housekeeper. The will was disputed on the ground that it bore intrinsic evidence of the deceased not having been in a sane state of mind at the time of making it. After having bequeathed his property to a stranger, the testator directed that his executors should “cause some parts of his bowels to be converted into fiddle-strings,—that others should be sublimed into smelling salts, and that the remainder of his body should be vitrified into lenses for optical purposes”! He further added, in a letter attached to his will,—“the world may think this to be done in a spirit of singularity or whim; but I have a mortal aversion to funeral pomp, and I wish my body to be converted into purposes useful to mankind.” Sir H. Jenner, in giving judgment, held that insanity was not proved;—the facts
merely amounted to eccentricity, and on this ground he pronounced for the validity of the will. It was proved that the deceased had conducted his affairs with great shrewdness and ability; that he not only did not labour under imbecility, but that he had been always treated during life as a person of indisputable capacity by those with whom he had to deal. The best rule to guide the Court, the judge remarked, was the conduct of parties towards the deceased; and the acts of his relatives evinced no distrust of his sanity or capacity while he was living. The deceased had always been noted for his eccentric habits, and he had actually consulted a physician upon the possibility of his body being devoted to chemical experiments after death. In the case of Mudway v. Croft (Prerog. Court, Aug. 1843), a will contested on the ground of insanity, but defended on the plea of eccentricity, Sir H. J. Fust said. — "It is the prolonged departure, without an adequate external cause, from the state of feeling and modes of thinking usual to the individual when in health, that is the true feature of disorder in mind." See also the case of Waring v. Waring (Prerog. Court, Feb. 1847.) The case of Yglesias v. Dyke (Prerog. Court, May 1852) presents some singular points of interest, in reference to the distinction between eccentricity and insanity. The testatrix had bequeathed by her will a considerable amount of property, which, as she was illegitimate, and as it was alleged incompetent to make a will, was claimed by the Crown. It was proved that she was of dirty habits, and among other facts that she kept twelve or fourteen dogs of both sexes, which were provided with kennels in her drawing-room! Two of the dogs slept in the same room, and one, which was blind, slept in the same bed with her! The testatrix also had a propensity for guinea-pigs, and was subject to some singular delusions. Some evidence was adduced to show that, in spite of these strange freaks, she was able to manage her own affairs; but the Court pronounced against the validity of the will, on the ground that the testatrix had for a long period laboured under insane delusions, and there was no proof that these had ceased. Her eccentricity was the result of insanity. Nothing is more common than to find this propensity for animals existing among females who live solitary or secluded lives. One old lady whom I knew generally kept her sitting-room full of monkeys, to the great annoyance of her visitors. She was a woman of good family, and of a shrewd and strong mind, well able to look after her affairs and to dispose of her property. She was considered to be eccentric, but there was no trace of insanity about her. Other females are not happy unless surrounded by parrots, or unless their sitting-rooms are converted into aviaries for all kinds of birds. In Mrs. Cumming's case (ante, p. 891), it was alleged that this lady had a strong propensity for cats; these animals being provided with meals at regular hours, and furnished with
plates and napkins. In this case a verdict of insanity was returned, not so much on account of the attention shown to the cats, as from her acts in reference to her property, and from her association with certain persons who appear to have taken advantage of her intellectual weakness. The fact is, this propensity for animals proves nothing in relation to the existence of insanity, unless there be good evidence of intellectual aberration. See the case of *Dryden v. Fryer* (Q. B. Dec. 1850), *Journal of Psychol. Med.* 1851, p. 285.

*Wills in senile dementia.*—Wills made in incipient dementia arising from extreme age (senile imbecility) are sometimes disputed, either on the ground of mental deficiency, or from the testator, owing to weakness of mind, having been subjected to control and influence on the part of interested persons. If a medical man be present when a will is made, he may easily satisfy himself of the state of mind of a testator, by requiring him to repeat from memory the mode in which he has disposed of the bulk of his property. Medical men have sometimes placed themselves in a serious position by becoming witnesses to wills without first assuring themselves of the actual mental condition of the testator (case of the *Duchess of Manchester*, ante, p. 902). It would always be a good ground of justification, if, at the request of the witness, the testator had been made to repeat substantially the leading provisions of his will from memory. If a dying or sick person cannot do this without prompting or suggestion, there is reason to believe that he has not a sane and disposing mind. It has been observed on some occasions, when the mind has been weakened by disease, or infirmity from age, that it has suddenly cleared up before death, and the person has unexpectedly shown a disposing capacity. (Ann d’Hyg. 1831, 360.) In the case of *Durnell v. Corfield* (Prerog. Court, July 1844), where an old man of weakened capacity had made a will in favour of his medical attendant, Dr. Lushington held that there must be the clearest proof, not only of the *factum* of the instrument, but of the testator’s knowledge of its contents. (Law Times, July 27, 1844.)

I am indebted to a learned judge for the following note:—“Another case may be noticed, which often occurs in the experience of lawyers, and to which, in attendance on aged persons, medical gentlemen do not sufficiently attend. A person’s mind in extreme old age may be quite intelligent, his understanding of business clear, and his competency to converse upon and transact such undoubted, and his bodily strength good; but there may grow upon him such a fear and dread of relatives who may have surrounded him, and on whom he may have become perfectly dependent, that his nervous system is wholly overcome, and he becomes a mere child and tool in the hands of those about him, so that he has no power to exert his mind in opposition to their
The plea of insanity — circumstantial evidence given at the trial.

CHAPTER

THE PLEA OF INSANITY — CIRCUMSTANTIAL EVIDENCE

ADMISSIBLE. HOMICIDAL MURDER.

CAUSES — SYMPTOMS — DEGREES
severity. The rule of law on this subject is, that no man is responsible like a sane person for any act committed by him while in a state of insanity. The plea may be raised for the smallest offence up to the highest crime — murder; but it is rarely raised in respect to smaller offences, because the close confinement to which an accused person, if found insane, would necessarily be subjected, would often be a heavier punishment than that which the law actually prescribes for the offence which he may have committed. In a case of felonious assault, it was urged by counsel in defence, that the prisoner was insane; but the evidence on this point was not by any means conclusive,—when it was intimated by the Court that, if this plea were admitted, the party would probably undergo a much longer imprisonment, than if on conviction he received the legal punishment for the offence! (See the case of the Queen v. Reynolds, Bodmin Aut. Ass. 1843.) The judge is reported to have said there was no proof of insanity. If the prisoner was pronounced insane, he might be imprisoned for life, and therefore he did not think that finding would benefit him! A verdict of guilty was returned, and the man was sentenced to eighteen months' imprisonment. The case shows at least that a defence of this kind may be sometimes indiscreetly put forward. Such a mode of dealing with the plea of insanity, i.e. of making it a question of expediency dependent on the amount of punishment for the offence, must be pronounced as unsafe and indefensible. Murder, incendiaryism, and theft are the crimes for which the plea of insanity is commonly raised; and it has been generally confined in this country to those cases in which persons have been charged with murder or attempts at murder.

Murder may be perpetrated by one who is obviously labouring under delirium or violent mania, or by an idiot or imbecile. Apart from the circumstances connected with the criminal act there may be evidence of such a state of mind in the person as at once to exonerate him from that amount of responsibility which is exacted from one who is sane. The appearance of the accused, or the testimony of a medical man, renders it unnecessary to go into the evidence, and a verdict is returned accordingly. The cases of difficulty are those in which insanity presents itself in a doubtful aspect. Mania or imbecility may be pleaded, but it may be of so slight a nature as not legally to justify an acquittal for murder.

In the case of Reg. v. Pate, tried in 1850 at the Central Criminal Court, the prisoner was indicted for an assault on the Queen. It was proved that he had been guilty of strange and eccentric, and even that which some might call insane, conduct, but there was no evidence to show that he had not a reasonable control over his actions. Dr. Conolly admitted that the prisoner was labouring under no delusion, that he knew the distinction between a right and a wrong action, but was subject to sudden impulses of
responsibility in criminal cases.

passion. He attributed his act to some sudden impulse which he was quite unable to control. Other witnesses deposed that in their opinion, although the prisoner was fully conscious of his act, he was insane. The late Baron Alderson, who tried the case, observed, in charging the jury, that it was not because a man was insane that he was unpunishable; and he must say that upon this point there was generally a very grievous delusion in the minds of medical men. "The only insanity which legally excuses a man for his acts, was that species of delusion which conducted and drove him to commit the act alleged against him. They ought to have a proof of a formed disease of the mind, a disease existing before the act was committed, and which made the person accused incapable of knowing at the time he did the act that it was a wrong act for him to do." The jury convicted the prisoner, and he was sentenced to transportation. (Med. Gaz. xlv. p. 152; and Journ. Psychol. Med. 1850, p. 557.)

The plea of insanity was here, it appears to me, advanced upon very weak grounds. Had the prisoner assaulted a policeman instead of the Queen, he would have been fined or imprisoned, and nothing heard of the plea, although the rank of the persons assaulted can make no difference respecting the existence or non-existence of a diseased state of mind. (See some excellent remarks on this case by Dr. Forbes Winslow, Journal Psychol. Med. 1850, p. 445.)

From the summimg up of the learned judge in this case, it would appear that the existence of one degree of insanity admits of punishment for crime, while the existence of another degree excuses it. As it has been already remarked in speaking of testimonial capacity, nothing can be more absurd than to apply one general term "insanity" to the condition of all persons affected with mental disorder, and to pronounce them therefore all incompetent or all incapable, when common sense suggests that we are bound to inquire into the amount of capacity in each case. If all persons are to be excused from responsibility for crimes or offences, because they entertain certain delusions, or are guilty of eccentricity, it would be better at once to make one general rule, and render all their civil acts void, and at the same time give them the benefit of irresponsibility for any criminal acts, without inquiring into the degree in which insanity exists. Such a practice would hardly be compatible with the due exercise of justice, or with the safety of society. Admitting that in this case the accused was to a certain extent insane, there was a sufficient degree of sanity about him, as indicated by his general conduct, to justify conviction and punishment. If, however, according to the ruling of the learned judge, we are always to insist upon the clear proof of a disease of the mind existing before the act committed, it is clear that an act committed under a sudden access of insanity, by a person not previously labouring under
DEGREES OF INSANITY.

Delusions, would be punishable like that of a sane criminal. (See the cases of Brixey, p. 925; and Ross Touchett, post.)

Dr. Wood, who has lately written on this subject, repudiates the doctrine that an insane person is necessarily irresponsible, and therefore unpunishable. "All who have had the opportunity of studying insanity know full well that, with comparatively few exceptions, insane persons are not only powerfully influenced, but materially controlled, by the same motives which influence and control those who are still mixing in the world, and who have never been suspected of mental derangement." (Plea of Insanity, 1851, p. 4.)

The great difference of opinion which exists between physicians and jurists in reference to this plea appears to me to consist in this:—Most jurists aver that no degree of insanity should exempt from punishment for crime, unless it has reached that point that the individual is utterly unconscious of the difference between right and wrong at the time of committing the alleged crime. Physicians, on the other hand, affirm that this is not a proper test of the existence of insanity; that those who are labouring under confirmed insanity, and who have been confined in asylums for years, are fully conscious of the difference between right and wrong, and are quite able to appreciate the consequences of their acts. Again, those who have patiently watched the insane for years, agree that the legal test of utter unconsciousness of right and wrong in the performance of acts would in reality apply only to persons who were suffering from delirium,—from a furious paroxysm of mania, or from confirmed idiocy; and that if the rule suggested by Mr. Warren,—that a person, in order to be acquitted on the ground of insanity, should be proved to be as unconscious of his act as a baby,—were strictly carried out, there is scarcely an inmate of an asylum who happened to destroy a keeper or attendant, who might not be convicted and executed for murder. Such a rule amounts to a reductio ad aburum: it would abolish all distinction between the sane and insane, between the responsible and the irresponsible, and it would consign to the same punishment the confirmed lunatic and the sane criminal. This species of baby-unconsciousness of action exists in idiots as well as in furious maniacs, but not in the majority of lunatics; and it may be safely asserted that, if this criterion be the true one, acquittals on the ground of insanity have involved a series of gross mistakes for the last fifty years. The only irresponsible lunatics, according to Mr. Warren, are precisely those who would not even have reason enough to plead to an indictment. Thus while the medical profession is condemned for adopting opinions which would lead to the acquittal of criminals, the writer recommends a rule which would certainly lead to the execution of the greater number of confirmed lunatics charged with acts of homicide. The practical failure of
such a rule is manifest, when it is found that persons who have destroyed life with a perfect consciousness of the wrongfulness of their acts are frequently acquitted. In the case of Dadd, who was acquitted on the ground of insanity, and who was proved to be a confirmed lunatic, it transpired that the man had actually provided himself with a passport and fled to France after destroying his father! (See Wood on the Plea of Insanity, p. 41.) It may be said that the consciousness of the insane is an insane consciousness, while the law implies the consciousness of a sound mind, but this involves a petio principii. There are numerous cases of acquittal, however, in which, until the act of homicide was committed, there was no imputation either against the sanity, or the same consciousness, of the accused.

Having pointed out these inconsistencies, it is only proper to acknowledge that in theory the English law would punish a lunatic just as it would punish a sane man, provided the lunatic "had that degree of intellect which enabled him to know and distinguish between right and wrong; if he knew what would be the effects of his crime, and consciously committed it; and if with that consciousness he wilfully committed it." In practice, however, it is placed beyond doubt that some who ought upon these rules to be held responsible are acquitted on the legal fiction that they were unconscious (or only insanely conscious) of the wrongfulness of their acts. Dr. Wood states, that of thirty-three males confined as lunatics in Bethlem, who had actually committed murder, not including those where an unsuccessful attempt was made to perpetrate the same crime, three were reported sane; and he feels quite satisfied that two of these were not insane at the time they committed the murders: and of the fifteen males who had actually committed murder, five were reported sane, and two of them ought, in his judgment, never to have been acquitted on the ground of insanity. (Plea, p. 50.) These facts, then, are sufficient to show that the rule of law generally adopted in practice does not err on the side of severity. The only complaint that can be made is, that it operates with uncertainty. This question has been fully and ably examined by Dr. Bucknill. (Unsoundness of mind in relation to criminal acts, 1854, pp. 5. 16. 39.)

The attempt to establish this plea in cases of murder by poison has generally ended in failure, although there may even have been proof of hereditary insanity. (Reg. v. Gallop, Somerset Winter Ass. 1844; and Reg. v. Allsutt, C. C. C., Dec. 1847.) The crime of poisoning indicates malice and deliberation in a greater degree than it would be in general safe to admit as co-existing with a state of insanity. Alison, however, mentions one case of acquittal (Sparrow, 1829), in which this plea was admitted. The woman poured a large quantity of vitriolic acid down the throat of her own child. She then ran to a neighbour's
house in a state of evident derangement, saying that she had killed the devil. Her insanity was clearly proved, and she was acquitted. (Crim. Law. 648.) When the defence of insanity is set up in order to warrant the jury in acquitting a prisoner on a charge of murder, it must be proved affirmatively that he is insane in a certain legal sense: if the fact be left in doubt, and if the crime charged in the indictment be proved, it is their duty to convict him. (Reg. v. Stokes, 3 Car. and Kir., 185.) It is proper that a medical witness should remember, in examining an accused party, who is alleged to have committed a crime while labouring under insanity, that the plea may be good, and yet the individual be sane, when examined. This was observed in a case of a lunatic, who killed his mother in February 1843. There was no doubt that he was insane at the time of the act; but two days afterwards he was found to be of perfectly sound mind. This sudden restoration to reason is sometimes met with in cases of homicidal mania. For a remarkable case of this description, where the motive of a man in killing his wife was apparently jealousy, see report by MM. Leuret and Ollivier. (Ann. d'Hyg. 1843, ii. 187; also 1836, ii. 122.) Lord Hale mentions a case, in which a woman, soon after her delivery, killed her infant. She confessed the crime, was carried to prison, fell into a deep sleep, awakened quite sane, and wondered how she came there. (See also the case of M'Callum, Alison, 650.) It is customary to say that they who commit these heinous crimes while labouring under insanity, are irresponsible. By this we are not to understand that they are allowed to go free. On the contrary, they are subjected to a close confinement, commonly perpetual, as it assuredly ought to be in all cases of murder: but depending on their recovery in respect to crimes of less magnitude. A power is vested in the executive only, to discharge recovered criminal lunatics, according to circumstances.

Medical opinions.—Some doubt has existed whether a medical witness, on a trial in which a plea of insanity is raised, could be asked his opinion respecting the state of the prisoner's mind at the time of the commission of the alleged crime,—whether the accused was conscious at the time of doing the act that he was acting contrary to law, or whether he was then labouring under any and what delusion. It has been decided, by fourteen judges out of fifteen, that facts tending to lead to a strong suspicion of insanity must be proved and admitted, before the opinions of medical witnesses can be received on these points. (See Med. Gaz. xlvi. p. 240.)

HOMICIDAL MONOMANIA.

Homicidal mania or monomania is commonly defined to be a state of partial insanity, accompanied by an impulse to the perpetration of murder. Persons who may not appear to labour
under any intellectual aberration, are liable to be seized with a sudden impulse, under which they may destroy those to whom they are most fondly attached, or any person who may happen at the time to be involved in the subject of their delusion. Sometimes the impulse is long felt, but concealed and restrained: there may be merely signs of depression and melancholy about the individual, and eccentric or wayward habits, but nothing to lead to a suspicion of the fearful contention which may be going on within the mind. Occasionally murder is perpetrated with great deliberation and apparently under all the marks of sanity. These cases are rendered difficult by the fact that there may be no distinct proof of the existence, past or present, of any disorder of the mind, so that it would appear the chief evidence of the existence of insanity is in the act itself: of the existence of insanity, in the common or legal acceptance of the term, before and after the perpetration of the crime, there may be either no evidence whatever, or it may be so slight as not to amount to proof. Such cases are regarded and described by some medico-legal writers as instances of insanity of the moral feelings only, and this condition has been called "Moral insanity" (ante, page 870). Its existence as a state independent of a simultaneous disturbance of the reason or intellect, is denied by the great majority of lawyers; and there is no doubt that an unrestricted admission of the doctrine would go far to do away with all punishment for crime, for it would render it impossible to draw a line between (moral) insanity and moral depravity. "Moral Insanity with a sound mind, it is contended, is a contradiction in principle; and whenever the mind is sound, it is further argued,—a man's conscience and sense of right and wrong will always be sufficient to enable him to restrain evil desires and impulses." It appears to me that the great difference of opinion which exists on the subject between legal and medical authorities, turns rather upon the signification of words, than upon any disagreement on the facts or the practical inferences to be drawn from them.

Causes.—The causes of homicidal monomania are assigned by Esquirol to cerebral irritation induced by bodily disease, excessive nervous excitement, vicious education, erroneous notions of religion, grief, destitution, and the power of imitation. With respect to the latter, it is a fact that the publicity given to horrible occurrences often excites a homicidal feeling (see case of Hon. R. Touchett, post, p. 931). The sight of a weapon, or of the intended victim, also determines in an instant the perpetration of the act—the individual feeling himself drawn on by an irrational impulse which he can neither resist nor control. Disordered menstruation, arising from sympathy of the uterus with the brain, may likewise operate as a cause; and this it is the more important to observe, because the person affected may not
have previously manifested any sign whatever of intellectual or moral insanity. (Case of Brizey, post, p. 926.) Esquirol alludes to the case of a female, who at every menstrual period experienced a strong desire to kill her husband and children, especially when she saw them lying asleep. Parturition is likewise a cause, and in this case the disorder may assume the form of what is called Puerperal Mania. (See post, p. 948.) It is important for a medical jurist to bear in mind, that persons who are likely to be attacked by homicidal mania are not always characterised by a gloomy, melancholic, or irritable disposition: the disorder sometimes shows itself in those who have been remarkable for their kind and gentle demeanour and quiet habits. In these cases, the murderous disposition gives no warning of its existence: this condition, may, however, be sometimes indicated by a sudden change of character, corresponding to a sudden access of insanity.

**Symptoms.**—Homicidal mania, in its more common form, may make its appearance at all ages, even, it is said, in children not more than eight or ten years old (?):—it is occasionally periodical, and the paroxysm of insanity is preceded by symptoms of general excitement. The patient experiences colicky pains, and a sense of heat in the abdomen or chest,—headache, restlessness,—the face is flushed or very pale,—the pulse hard and full, and the whole body is in a state of convulsive tremor. An act of violence is committed without warning, and the patient appears as if relieved from some oppressive feeling. He may be calm, and express neither regret, remorse, nor fear. He may coolly contemplate his victim, confess the deed, and at once surrender himself to justice. In some rare instances he may conceal himself, hide the weapon, and endeavour to do away with all traces of the crime. The symptoms just described, have been observed to be more aggravated in proportion as the homicidal impulse was strong. The propensity to kill is sometimes a fixed idea, at others intermittent; and the patient can no more banish it from his thoughts than a person afflicted with insanity can divest himself of the delusive ideas which occupy his mind. (Esquirol, ii. 105.) It has been supposed that Esquirol here implies a state in which there is no perversion of intellect. The facts which he mentions, however, clearly prove the contrary, for if a patient has not the power to banish from his thoughts this propensity to kill, he has passed beyond the bounds of reason, and is really insane. The admission of this fact proves that his mind must be unsound. Esquirol observes,—before the perpetration of the act there may be no sign of irrational conversation or conduct: but he asks the question—Because there is no proof of irrationality, are we to assume that these persons possess reason? Is it possible to reconcile the existence of a rational state of mind with the murder of those who are most
dear to them? (Op. cit. ii. 102.) In Esquirol's view, therefore, it may be taken that mere perversion (insanity) of feelings, irrespective of some latent aberration of intellect, does not exist, and moral insanity is therefore a conventional term for a state in which the proofs of mental disturbance may not be so clear as in the generality of cases.

An erroneous notion prevails in the public mind, that a homicidal lunatic is easily to be distinguished from a sane criminal by some certain and invariable symptoms or characters, which it is the duty of a medical witness to display in evidence, and of a medico-legal writer to describe. But a perusal of the evidence given at a few trials will surely satisfy those who entertain this notion, that each case must stand by itself. It is easy to classify homicidal lunatics, and say that in one instance the murderous act was committed from a motive; i.e. revenge or jealousy; — in a second, from no motive, but from irresistible impulse; in a third, from illusion or delusive motive; i.e. mental delusion: — in a fourth, from perverted moral feeling, without any sign of intellectual aberration. This classification probably comprises all the varieties of homicidal insanity, but it does not help us to ascertain, in a doubtful case, whether the act was or was not committed under any of these psychological conditions. It enables us to classify those who are acquitted on the ground of insanity, but it entirely fails in giving us the power to distinguish a sane from an insane criminal, or a responsible from an irresponsible lunatic. According to M. Esquirol, whose views, more or less modified, are adopted by all writers on the medical jurisprudence of insanity, the facts hitherto observed indicate three degrees of homicidal mania: —

1. In the first the propensity to kill is connected with absurd motives or actual delusion. The individual would be at once pronounced insane by everybody. Cases of this description are not uncommon, and they create no difficulty whatever. The accused are rarely required even to plead to the charge.

2. In the second class, the desire to kill is connected with a known motive. It is difficult to suppose that the individual could have had any real or imaginary motive for the deed. He appears to be led on by a blind impulse.

3. In the third class, the impulse to kill is sudden, instantaneous, unreflecting and uncontrollable (plus forte que la volonté). The act of homicide is perpetrated without interest, without motive, and often on persons who are most fondly loved by the perpetrator. (Maladies Mentales, ii. 834.)

These three forms differ from each other only in degree; — the two first being strongly analogous to, but lighter modifications of, the third. All the cases which came before M. Esquirol had these features in common: — an irritable constitution, great excitability — singularity or eccentricity of character: and pre-
HOMICIDAL MANIA. LEGAL TESTS.

viciously to the manifestation of the homicidal feeling there was a gentle, kind, and affectionate disposition. As in other forms of insanity, there was some well-marked change of character in the mode of life; and this may be taken as a proof that there must have been some degree of intellectual disturbance. The period at which the disorder commenced and terminated could be easily defined, and the malady could be almost always referred to some moral or physical cause. In two cases it was traced to the change produced by puberty, and in four to the power of imitation. Attempts at suicide preceded or followed the attack: all wished to die, and some desired to be put to death like criminals. In none of the cases was there any motive for the act of homicide. M. Esquirol believes that there are well-marked distinctions between this state and that of the same criminal. Among these he enumerates, 1st, the want of accomplices in homicidal mania. 2nd, the criminal has always a motive — the act of murder is only a means for gratifying some other more or less criminal passion; and is almost always accompanied by some other wrongful act: the contrary exists in homicidal mania. 3d, the victims of the criminal are those who oppose his desires or his wishes; the victims of the monomaniacs are among those who are either indifferent, or who are the most dear to him. — 4th, the criminal endeavours to conceal, and if taken, denies the crime; if he confesses it, it is only with some reservation, and when circumstances are too strong against him; but he commonly denies it to the last moment. It is the reverse with the monomaniacs. The exceptions to which these characters are open will be considered hereafter. They have, undoubtedly, greater value in their combined than in their individual application, and when in any case they coexist, there is strong reason to believe that the accused party is irresponsible. The great difficulty in these cases, however, is to distinguish moral depravity from insanity. I agree with a medico-legal writer on this subject, that "no hideousness of depravity can amount to proof of insanity, unsupported by some evidence of a judgment incapacitated, or of a will fettered by disease. In those cases of mental disorder in which the emotions are perverted, and where there is no clear proof of deranged intellect,—cases which do from time to time occur,—the presumption of insanity in regard to a criminal action has to be upheld by evidence of a suspension of the will." (Jamieson's Lectures on the Med. Jur of Insanity, Med. Gaz. xlviii. p. 181.) But it is not possible in many cases to produce satisfactory evidence of the suspension of the will: this suspension can only be assumed from the act,—a dangerous assumption, and one that might lead to the confusion of crime with insanity.

Legal tests. — Admitting the existence of a state of homicidal mania as thus defined by Esquirol, it will become a question, how, when pleaded for one charged with murder, it is to be
distinguished from a case in which the crime has been perpetrated by a really sane person. Tests, both medical and legal, have been proposed. The legal test was explicitly stated in the following terms by the whole of the judges in conference, in answer to queries put by the House of Lords in reference to the case of M'Naughten, who was tried and acquitted on the ground of insanity (June 19th, 1843).

Notwithstanding a party commits a wrong act while labouring under the idea that he was redressing a supposed grievance or injury, or under the impression of obtaining some public or private benefit, he is liable to punishment. The jury ought in all cases to be told that every man should be considered of sane mind until the contrary was clearly proved in evidence; that before a plea of insanity should be allowed, undoubted evidence ought to be adduced that the accused was of diseased mind, and that at the time he committed the act, he was not conscious of right or wrong. Every person was supposed to know what the law was, and therefore nothing could justify a wrong act, except it was clearly proved that the party did not know right from wrong. If that was not satisfactorily proved, the accused was liable to punishment. If the delusion under which a person laboured were only partial, the party accused was equally liable with a person of sane mind. If the accused killed another in self-defence, he would be entitled to an acquittal; but if the crime were committed for any supposed injury, he would then be liable to the punishment awarded by the laws to his crime. (B. and F. M. R., July 1843, p. 273.)

It would appear from this, that the law, in order to render a man responsible for a crime, looks for a consciousness of right and wrong, and a knowledge of the consequences of the act. Thus, the complete possession of reason is not essential to constitute the legal responsibility of an offender; and it is also to be inferred from the results of several cases, that a man may be civilly incompetent, but sufficiently sane to be made criminally responsible. The proofs required in the two cases are essentially distinct. It has been objected to this legal test, that it is insufficient for the purpose intended: it cannot, in a large majority of cases, enable us to distinguish the insane homicide from the sane criminal. Many insane persons have committed acts which they knew to be wrong, and of the criminality of which they were at the time perfectly conscious. They have been known to murder others, in order to receive the punishment of death at the hands of the law; and therefore they must have been conscious of the wrongfulness or rather of the illegality of the act which they were perpetrating, and have known that they were committing an offence against the law of man. In short, the criminal nature of the act has often been the sole motive for its perpetration! (See the case of Touchett, p. 931;
also another case, Ann. d’Hyg. 1842, i. 363.) It has been suggested with some truth, that it is rather the imperfect or defective appreciation of the motives to right or against wrong action, which leads to crime among the insane, and not the mere ignorance of right and wrong. Most lunatics have an abstract knowledge that right is right and wrong wrong, but in true insanity the voluntary power to control thought and actions and to regulate conduct by this standard, is impaired, limited, or overruled by insane motives. A lunatic may have the power of distinguishing right from wrong, but he has not the power of choosing right from wrong. A criminal is punishable not merely because he has the power of distinguishing right from wrong, but because he voluntarily does the wrong, having the power to choose the right. (Jamieson’s Lectures on Insanity, Med. Gaz. xlvi. p. 827.) The case of Hudfield, who was tried for shooting at George III. and acquitted on the ground of insanity, furnishes an example of the existence of insane delusion, coupled with a knowledge of the consequences of the act which he was about to commit. He knew that in firing at the King he was doing what was contrary to law, and that the punishment of death was attached to the crime of assassination; but the motive for the crime was that he might be put to death by others,—he would not take his own life. Again, Martin, the incendiary, admitted that he knew he was doing wrong according to the law of man, when he set fire to York Cathedral: he was conscious that the act was illegal, but he said he had the command of God to do it. Thus, then, we find that a full consciousness of the illegality or wrongfulness of an act may exist in a man’s mind at the time of its perpetration, and yet in spite of this, he may be legally acquitted on the ground of insanity. But it may be said this is an insane or delusive consciousness, and part of the insanity under which he labours. Such an inference is not, however, justified by the facts.

Medical tests.—It will now be proper to examine the tests which have been proposed by medical jurists for detecting these cases of homicidal mania. 1. The acts of homicide have generally been preceded by other striking peculiari of conduct in the individual,—often by a total change of character. 2. They have in many instances previously or subsequently attempted suicide: they have expressed a wish to die or to be executed as criminals. These supposed criteria have been repeatedly and very properly rejected, when tendered as medical proofs of insanity in Courts of Law. They are of too vague a nature, and apply as much to cases of moral depravity as of actual insanity; in short, if these were admitted as proofs, they would serve as a convenient shelter from punishment for many sane criminals.

3. Motive for crime.—The acts are without motive; they are in opposition to all human motives. A man known to have
been tenderly attached to his wife and children, murders them: a fond mother destroys her infant. It is hereby assumed or implied that sane men never commit a crime without an apparent motive; and that an insane person never has a motive, or one of a delusive nature only, in the perpetration of a criminal act. If these positions were true, it would be very easy to distinguish a sane from an insane criminal; but the rule wholly fails in practice. In the first place, the non-discovery is here taken as a proof of the non-existence of a motive; while it is undoubtedly true that motives may exist for many atrocious criminal acts without our being able to discover them—a fact proved by the numerous recorded confessions of criminals before execution, in cases in which, until these confessions were made, no motive for the perpetration of the crime had appeared to the acutest minds. (Reg. v. Hatto, Bucks Lent Ass. 1854.) In the case of Courvoisier, who was convicted of the murder of Lord William Russell in June 1840, it was the undue reliance upon this alleged criterion, before the secret proofs of guilt accidentally came out, that led many to believe he could not have committed the crime; and the “absence of motive” was urged by his counsel as the strongest proof of the man’s innocence. It was ingeniously contended “that the most trifling action of human life had its spring from some motive or other.” This is undoubtedly true, but it is not always in the power of a man untainted with crime to detect and unravel the motives which influence criminals in the perpetration of murder. No reasonable motive was ever discovered for the atrocious murders and mutilations perpetrated by Greenacre and Good; yet these persons were very properly made responsible for their crimes! It would be a fatal error to infer insanity from what is termed the inadequacy of motive. In the inquiry whether a particular man committed the offence, this consideration may be of great weight,—of very little, however, when the inquiry is whether the man who did it, is insane. On the trial of Francis for shooting at the Queen, the main ground for the defence was, that the prisoner had no motive for the act, and therefore was irresponsible; but he was convicted. It is difficult to comprehend under what circumstances any motive for such an act as this could exist: and therefore the admission of such a defence would have been like laying down a rule, that evidence of the perpetration of so heinous a crime should in all cases be taken per se as a proof of the existence of an irresponsible state of mind! Crimes have been sometimes committed without any apparent motive by sane individuals, who were at the time perfectly aware of the criminality of their conduct. No mark of insanity or delusion could be discovered about them, and they had nothing to say in their defence. They have, however, been very properly held responsible. On the other hand, lunatics confined in a lunatic asylum have been
known to be influenced by motives in the perpetration of crimes. Thus they have often murdered their keepers in revenge for ill-treatment which they have experienced at their hands. (See the case of the Queen v. Farmer, York Spring Assizes, 1837.) This man was acquitted as insane, while the clear motive for the homicide was revenge and ill-feeling. In another case the act of murder was perpetrated from jealousy. (Reg. v. Goule, Durham Summer Ass. 1845.) On the whole, the conclusion with respect to this assumed criterion is, that an absence of motive may, when there are other strong proofs of insanity, favour the view of irresponsibility for crime; but the non-discovery of a motive for a criminal act cannot of itself be taken as a proof of the existence of insanity or homicidal mania in the perpetrator. It is right to state, however, that the law invariably acts on the humane principle — that the absence of a sufficient, or reasonable, motive is a presumption in favour of insanity. The acts of the insane are generally the results of motives based on delusion. In cases of idiocy an act of homicide has been committed merely as a result of imitation; and in imbecility, from motives of an absurd and unreasonable kind. I am indebted to Dr. Sutherland for some of the particulars of the case of a young man, affected with imbecility, upon whom an inquisition was held in 1843. He was a person of childish manners, and among the symptoms of imbecility there showed itself a strong propensity for windmills. He particularly wished to be tied to one of the arms of the mill when they were going round. He would go any distance to see a windmill, and would sit watching one for days together. His friends removed him to a place where there were no mills, in the hope that this strange propensity would wear away. He collected a number of lucifer matches and set fire to the house where Dr. Sutherland attended him, with a view that he might escape during the confusion to the land of windmills; and on another occasion he enticed a child into a wood, and in attempting to murder it, cut and mangled its limbs with a knife in a horrible manner. How would any sane person have connected this propensity for windmills with the attempts at arson and murder? Yet it turned out that he had taken the resolution to commit these crimes in the hope that he should be removed to some place where there would be a mill! (See also Report on Lunatics, Quart. Rev., 1844.)

4. Confession.—The subsequent conduct of the individual:—he seeks no escape, delivers himself up to justice, and acknowledges the crime laid to his charge. This is commonly characteristic of homicidal mania; for by the sane criminal every attempt is generally made to conceal all traces of the crime, and he denies it to the last. A case occurred in September, 1843, which, however, shows the fallacy of this criterion. A man named Dadd, murdered his father at Cobham, under circumstances
strongly indicative of homicidal mania; he fled to France after
the perpetration of the crime, and was subsequently tried and
acquitted on the ground of insanity. (See also another case.
Ann. d’Hyg. 1829, ii. 392.) On the other hand, it must be re-
membered that sane persons who destroy the lives of others
through revenge or anger, often perpetrate murder openly, and
do not attempt to deny or conceal the crime; for they know
that denial or attempt at concealment would be hopeless. Again,
a morbid love of notoriety will often induce sane criminals to
attempt assassination under circumstances where the attempt may
necessarily be witnessed by hundreds, and there can be no pos-
sibility of escape. The attacks made some years since upon the
life of the Queen are sufficient to bear out this statement.

5. Accomplices.—The sane murderer has generally accomplices
in vice or crime; the homicidal monomaniac has not. Upon
this it may be observed that some of the most atrocious murders
committed in modern times, as those perpetrated by Greenacre,
Good, Courvoisier, and others, were the acts of solitary indivi-
duals, who had neither accomplices nor any assignable inducements
leading to the commission of the crimes. It is, however, a fact
so far in favour of the existence of homicidal insanity, that the
insane never have accomplices in the acts which they perpetrate.
These criteria can hardly be described as medical; they are cir-
cumstances upon which a non-professional man may form just
as safe a judgment, as one who has made insanity a special study.

6. Delusion in the act.—The presence of delusion has been said to
characterise an act of homicidal monomania, while premeditation,
precaution, and concealment, have been considered the essential
features of the act of a sane criminal. With respect to delusion,
it has been decided that the mere proof of the existence of this
does not excuse the act: if the delusion be partial, the party ac-
cused is still responsible; — and if the crime were committed for
an imaginary injury, he would be held equally responsible. (See
ante, p. 918.) Much stress was formerly laid upon the delusion
being connected with the act in cases of alleged insanity; but it
must be remembered that, except by the confessions of insane
persons during convalescence, it is not commonly easy for a sane
mind to connect their most simple acts with the delusions under
which they labour. Every act of homicide perpetrated by a really
insane person is doubtless connected with some delusion with
which he is affected; but it by no means follows, that one who is
sane should always be able to make out this connection; and it
would be therefore unjust to rest the irresponsibility of the ac-
cused upon an accidental discovery of this kind. Let the following
cases show how little a sane person is able to connect the delusions
of the insane with their acts. Marc mentions that a patient of
his was continually in the habit of licking the plaster from the
walls of his cell,—in some places they had been licked quite bare
by this disgusting practice. It was only accidentally discovered that the act was connected with a delusion, under which the man laboured, that he was licking and tasting the most delicious fruits! Another patient was in the habit of running up and down the ward, beating his own shadow with a stick. It turned out that he fancied this shadow to be an army of rats in constant pursuit of him! Lord Erakine’s doctrine in Hadfield’s case is, therefore, medically speaking, wholly untenable. The connection of a delusion with an act where it can be really traced, may serve to exculpate an accused party; but the non-establishment of this connection proves nothing.

It may be further observed, that premeditation and precaution are met with in crimes committed both by sane and insane criminals; although these, with subsequent concealment, are certainly strong characteristics of sanity. It should be a question for a jury, whether, when they are proved to have existed in any criminal act, there might not have been such a power of self-control in the person, although in some degree insane, as to justify the application of punishment. It is not the presence of a slight degree of mental aberration which necessarily indicates the loss of power of controlling actions. Are such individuals less beyond the influence of example than one-half of the sane criminals who are punished?

Summary.—The foregoing considerations lead to the inference, that there are no certain legal or medical tests, whereby homicidal mania can be proved to exist. Each case must be determined by the circumstances attending it: but the true test for irresponsibility in the ambiguous cases appears to be, whether the person, at the time of the commission of the crime, had or had not a sufficient power of control to govern his actions. This involves the consideration, not only whether insanity existed, but whether it had reached a degree to destroy (not consciousness of the act but) volition. If from circumstances it can be inferred that an accused person had this power, whether his case may fall within the above rules or not, he should be made responsible, and rendered liable to punishment. If, however, he was led to the perpetration of the act by an insane impulse, or, in other words, by an impulse which his mental condition did not allow him to control (lésion de volonté, Esquirol), he is entitled to an acquittal as an irresponsible agent. The power of controlling an act appears to me to imply the existence of such a state of sanity as to render the party responsible: and when there is this want of control, it may be fairly concluded that the person is irresponsible. (Reg. v. Brixey, C. C. C., May 1845, p. 926.) A test somewhat similar to this is constantly applied by juries, under the direction of our judges, to distinguish murder from manslaughter; and it is quite certain that sanity and homicidal mania are not more nicely blended, than are occasionally the shades of
guilt whereby manslaughter passes into murder. The manner and circumstances under which a crime is committed will often allow a fair inference to be drawn as to how far a power of self-control existed or was exercised. A man in a violent fit of mania or delirium rushes with a drawn sword into an open street and stabs the first person whom he meets; — another, worn out by poverty and destitution, destroys his wife and children to prevent them from starving, and then probably attempts to murder himself; these are cases in which there is fair ground to entertain a plea of irresponsibility; but when we find a man (Reg. v. M'Naughten) lurking for many days together in a particular locality, having about him a loaded weapon, — watching a particular individual who frequents that locality, — a man who does not face the individual and shoot him, but who coolly waits until he has an opportunity of discharging the weapon unobserved by his victim or others,—the circumstances appear to show such a perfect adaptation of means to ends, and such a power of controlling his actions, that one is quite at a loss to understand why a plea of irresponsibility should have been admitted. The acquittal was the more remarkable because there was no proof of general insanity and the crime was committed for a supposed injury. According to the rules laid down by the fifteen judges (ante, p. 918) arising out of this case, he should have been convicted.

**Test of irresponsibility.** — The test here proposed is more or less advocated by Esquirol, Marc, Ray, Pagan, Jamieson, and other writers on the medical jurisprudence of insanity. (Esquirol, Maladies Mentales, ii. 842.) M. Marc adopts throughout the opinions of Esquirol. (De la Folie, ii. 71.) Dr. Ray, an intelligent American writer, considers that all forms of homicidal monomania are characterised by an "irresistible motiveless impulse to destroy life;" (Med. Jur. of Insanity, 268;) and Dr. Pagan properly observes—"The very loss of the control over our actions which insanity infers, is that which renders the acts which are committed during its continuance undeserving of punishment." (Med. Jur. of Insanity, 211.) The test should be, according to Dr. Jamieson, "had the lunatic at the time of committing the deed a knowledge that it was criminal, and such a control over his actions, as ought, if exerted, to have hindered him from committing it?" (Med. Gaz. xlvi. p. 827.) Was his mind so disordered that he had lost the power of control which is possessed by a person in a sane state? Thus, then, it would appear, from the concurrent views of medico-legal writers and of experienced practical observers of the habits and conduct of the insane, that we have here a criterion whereby the responsibility or irresponsibility of an accused party ought to be tested; and although there will be some difficulty in determining how far an individual did or did not possess control over his act; — whether the im-
pulse was or was not insane and irresistible (impuissance de la volonté); yet it must be borne in mind that the same objection applies with equal force not only to the present legal test (the existence or non-existence of a sane consciousness of right or wrong under which persons are yearly acquitted or executed), but to every test or rule, medical or legal, that has hitherto been proposed by physician or jurist. There is as great (if not greater) difficulty in distinguishing sane from insane consciousness of right and wrong as in distinguishing a sane from an insane impulse in the perpetration of murder.

Cases in illustration. — It is well known that persons seized with a desire to kill, have been able, in some instances, to exercise a certain degree of control over their feelings, and have thus saved the lives of their intended victims, and themselves from the imputation of a heinous crime. Esquirol has recorded several instances of this kind. (Maladies Mentales, ii. 807.) The following case has been reported by Mr. Daniell. A patient labouring under disordered liver, without any sign of intellectual aberration, was found by him to be on one occasion in a state of great excitement. He confessed that whilst talking with his wife and family his eye caught the poker, — a desire to shed blood came upon him which he felt he could not control. He shut his eyes and tried to think of something else, but it was of no use. At last, he could bear it no longer, and with a voice of thunder he ordered them out of the room. Had they opposed him, he felt he must have murdered them all. (Proe. Med. Jour. Nov. 12, 1845.) This appears to have been a sudden fit of homicidal mania; and as such it presents a fearful picture of the contending feelings which agitate an individual labouring under it. There was here, it will be observed, not an entire deprivation of self-control, or he would have attacked his wife and children without giving them any warning.

The works of Marc, Esquirol, and Prichard, abound in illustrations of this form of monomania; but I prefer selecting some of those which have occurred in England. The following case was tried on the Midland Circuit, July 1837 (Reg. v. Greensmith). The prisoner in this case was charged with the murder of four of his children. The facts here to be related were partly brought out in evidence, and partly by his own confession. He was a person of industrious habits, and an affectionate father; but having fallen into distressed circumstances, he destroyed his children by strangling them, in order, as he said, that they might not be turned into the streets. The idea only came to him on the night of his perpetrating the crime. After he had strangled two of his children in bed, he went down stairs, where he remained some time; but thinking he might as well suffer for all as for two, he returned to the bed-room, and destroyed the two whom he had left alive. He shook hands with them before he
strangled them. He left the house and went to a neighbour, but said nothing of the murder, until he was apprehended the next day and taken before the coroner, when he made a full confession. Not one of the witnesses had ever observed the slightest indication of (intellectual) insanity about him. He made no defence; but several medical practitioners came forward to depose that he was insane. The surgeon of the gaol said that the man was feverish, complained of headache, and had been subject to disturbed sleep and sudden starts since the death of his wife a short time before. He spoke of the crime he had committed without the slightest excitement, and the medical witness said he had heard enough of the evidence to satisfy him that the prisoner could not have committed such a crime as this, and be in a sane state of mind. Dr. Blake, physician to the Nottingham Lunatic Asylum, said he was satisfied that the prisoner laboured under a delusion of mind. The prisoner’s grandmother and sister had been under his care, the latter for entertaining a similar delusion—namely, a desire to destroy herself and her children. The prisoner was found guilty, and sentence of death was passed upon him. By the active interference of Dr. Blake and others, he was subsequently reprieved on the ground of insanity. (See Med. Chir. Rev. xxviii. 84.)

The case of Reg. v. Brixey was tried at the Central Criminal Court, in June 1845. The prisoner was a quiet, inoffensive girl, a maid-servant in a respectable family. She had laboured under disordered menstruation, and, a short time before the occurrence, had shown violence of temper about trivial domestic matters. This was all the evidence of her alleged (intellectual) insanity— if we except that which was furnished by the act of murder. She procured a knife from the kitchen on some trivial pretext, and while the nurse was out of the room, cut the throat of her master’s infant child. She then went down stairs and told her master what she had done. She was perfectly conscious of the crime she had committed, she appeared to treat the act as a crime, and showed much anxiety to know whether she would be hanged or transported. There was not the slightest evidence that, at the time of the act or at any time previously, she had laboured under any delusion, or any intellectual aberration. The prisoner was acquitted on the ground of insanity, probably caused by obstructed menstruation. (Med. Gaz. xxxvi. 166, 167.) In trying this case by the medical rules laid down for detecting homicidal monomania (ante, p 919), we shall see that it falls under the 3rd, 4th, and 5th only; i.e. absence of motive,—no attempt to escape,—no accomplices. Admitting the probability of a connection existing between suppressed menstruation and insanity in the abstract, there was no proof of the existence of intellectual insanity in the case of this girl,—yet she was acquitted! The existence of insanity was a pure legal fiction
based on the act committed and on the mode in which it was
committed. In the defence of Brixy, the late Mr. Clarkson
uttered a plain medical and legal truth, in stating that “no
general rules can be applied to cases of this sort. Each case
must be decided by the peculiar facts which accompany it.”
Notwithstanding the precedent furnished by this case, and
another of a similar kind, Reg. v. Stowell (Med. Gaz. xlvii.
p. 569), a Court of Law will no doubt commonly look for
some clear and distinct proof of mental delusion or intellectual
aberration existing previously to or at the time of the perpe-
tration of the crime. If there be no proof of delusion or of failure
of intellect on the part of the accused, the plea of homicidal
insanity from irresistible impulse may still be rejected. In the
case of Reg. v. Burton (Huntingdon Summer Assizes, 1848),
the prisoner was indicted for the murder of his wife, by cutting
her throat. It appeared that he had no motive for killing her,
—that he had been previously unwell, and restless at night,
—that he did not attempt to conceal or deny the commission
of the crime, and that he expressed no sorrow or remorse
for it when perpetrated. The medical witness attributed the
act to a sudden homicidal impulse: the prisoner's reason
was not affected, and he had not laboured under delusions.
This appears to have been a proper view of the case. The
learned judge dissented from the medical opinion, because the
excuse of an irresistible impulse, coexisting with the full (?)
possession of reason, would justify any crime whatever. It is
highly probable that there was not a full possession of reason in
this case. No reasonable being would commit an act of this
nature under the circumstances mentioned. As in Greensmith's
case, there may have been delusion springing up in the mind
suddenly, and not revealed by the previous conduct or conver-
sation of the accused. There appears to have been no stronger
reason for convicting this prisoner than for convicting Brixy.
He was, nevertheless, found guilty, while Brixy was acquitted.

Among other cases, there are those of Reg. v. Frost, Norwich
Summer Ass. 1844; and Reg. v. Dickenson, C. C. C., March
1844. There are also the cases of Nicholas Steinberg, who cut
the throats of his wife and four children, and then destroyed him-
selves, in Sept. 1834; of Lucas, who destroyed his three children, in
March 1842; of Giles, who cut the throats of two of his infant
children at Hoxton, in Jan. 1843. In these instances, the un-
expected act of murder was accompanied by suicide. In the
case of Mrs. Brough (Guilford Summer Ass. 1854), it was
proved that the accused destroyed six of her children by cutting
their throats, and then attempted to destroy herself. She was
acquitted on the ground of insanity although there was no
proof of mental derangement. These cases may be regarded as
presenting fearful examples of that state which has been called
homicidal mania, in which there were no previous symptoms of intellectual aberration amounting to insanity in the common meaning of the term, or of any irregularity of conduct on the part of the homicides to justify the least interference with their civil liberty. A uniform feature of these cases is, that the murderous act was directed against those who were most closely connected with the homicides in blood, and to whom they were attached by the tenderest ties.

It appears to me that such crimes as these cannot be fairly or reasonably regarded as the acts of sane and responsible persons; and even those who deny the existence of such a form of insanity as homicidal monomania, are in general compelled to admit that these dreadful motiveless murders are the acts of insane and irresponsible agents. Thus a high legal authority remarks of Greensmith's case, that the "man's mind was clearly deranged — the motive — the mode of committing the acts, and his conduct all show an entire perversion of the understanding. Moral insanity is a term or a notion inapplicable to such a case." On this, it may be remarked, that the absence of the very conditions here relied on as so clear and obvious led to the man's conviction for murder, and it was only with some difficulty, and after an appeal from medical men, that the Secretary of State was induced to interfere. There was not the slightest proof of the existence of derangement of mind, except in so far as it was inferred from the nature of the crime committed. It may be a dangerous doctrine, to adduce the crime, or the mode of perpetrating it, as evidence of insanity, but such cases as these incontrovertibly prove that there are some instances in which this is almost the only procurable evidence. My friend Mr. Warren, who denies the existence of "moral insanity," quotes from a former edition of this work the cases of Greensmith and Brixey, in some remarks which he has made on the plea of insanity (Blackwood's Edinburgh Magazine, No. 421, p. 547), but he leaves it quite uncertain whether, in his judgment, the accused should have been executed for the murders as sane persons, or whether the acquittals on the ground of insanity were right and proper. It is desirable that questions of this kind should be resolved on principles susceptible of some practical application. If Greensmith and Brixey were not labouring under moral insanity, —homicidal mania, —or an uncontrollable impulse to murder, —it is clear by the result that their mental condition at the time of perpetrating these acts of murder was such as to justify their acquittal on the ground of insanity; and medical jurists do not ask for more than this, although the means by which they seek to obtain acquittals in such cases, appear objectionable and unsuited to legal dicta. To assert that there was an unconsciousness of the nature or criminality of the acts in either of these cases, would be conflicting with all the facts proved, and to con-
tend that consciousness of right and wrong, if it existed, was itself of an insane kind, would be a mere ex post facto assumption. The occasional existence of a state of homicidal mania appears to me to be fairly established by these two cases, for there was not, in either, the least evidence of previous intellectual aberration or of insane conduct, if we except the act perpetrated and the mode of perpetrating it. The acquittals produced no shock to public feeling, like certain acquittals of a really doubtful kind. Had not the homicides in some of the instances above mentioned destroyed themselves, it is most probable that they would have been acquitted on the ground of insanity. In the case of Staninought, an acquittal actually took place: this man, who had attempted suicide, recovered, was tried, acquitted on the ground of insanity, and he afterwards destroyed himself.

A great difference of opinion existed relative to the case of McNaughten, who was tried for the murder of Mr. Drummond (Jan. 7, 1843), and acquitted on the ground of insanity. There is hardly a doubt that, had the deceased given any personal offence to this individual before the perpetration of the act, he would have been convicted; if the deceased, from feeling annoyed at his following him, had struck him or pushed him away before the pistol was fired, it is most probable that the plea of insanity would not have been received. In the acquittal of this man, it is evident that considerable importance was attached to the non-discovery of a motive; for had any kind of motive been apparent, it is certain that an alleged "homicidal climax," occurring at the particular moment when the deceased's back was turned, and after several days' watching on the part of the assailant, would not have been admitted as a sufficient exculpatory plea! If we except the case of Oxford, tried for shooting at the Queen, there is perhaps no case on record in English jurisprudence in which the facts in support of the plea of insanity were so slight; and when the cases of Bellingham, Lees, and Cooper are considered, the two latter tried and executed within the last few years, it must be evident that great uncertainty prevails in the operation of this branch of our criminal law. Either some individuals are most improperly acquitted on the plea of insanity, or others are most unjustly executed. If the punishment of death were abolished, there is no doubt that less would be heard of this plea; but in the meantime, it is unfortunate that there is no other way of avoiding capital punishment, than by striving to make it appear that a criminal is insane! (See Prichard, 399.) It is on this point that medical witnesses seem to me to lose sight of their true position. In giving an opinion of the mental condition of an offender, it is no part of their province to modify that opinion according to the punishment which may follow if the plea be rejected, but solely according to the facts of the case. The Legislature
only is responsible for the punishment adjudged to crimes. Dr. Mayo has justly observed, that a medical witness is summoned to a Court of Justice in order to enable the judge and jury to arrive at certain practical conclusions. The question proposed to him involves a simple fact, and not its consequences, and if the latter consideration be entertained by him, it will be liable to bias his evidence on the fact, which is his legitimate topic. The definition of insanity becomes very expansive, when its expansion may become protective to a criminal with whom we may happen to sympathise. The question whether the accused is a responsible agent, is of a judicial nature: our evidence should be confined to the question whether the accused is insane in a certain sense or meaning in which it is understood, and defined by the law. (Medical Testimony and Evidence in cases of Lunacy, 1854, p. 9.)

A medical witness in these cases generally moulds his evidence to a foregone conclusion on the criminal responsibility of the accused, and he thus lays himself open to a remark from the judge, that he must not encroach on the functions of the jury.

It is certainly a great evil, that under the present mode of laying this question before a jury, the law operates most unequally. One case becomes a subject of prominent public interest, and every exertion is made to construe the most trivial eccentricities of character into proofs of insanity: an acquittal follows. Another case tried at the Assises, may excite no interest,—it is left to itself,—the accused is convicted, and either executed or otherwise punished; although the evidence of insanity, had it been as carefully sought for and brought out, would have been as strong in this as in the former instance (Reg. v. Stolzer, Cent. Crim. Court, Nov. 1843).

The case of Reg. v. Laurence (Lewes Lent Ass. 1844), affords a remarkable contrast to that of McNaughten. The prisoner had been arrested by a constable for a petty theft: he was taken to the police-station, where the inspector, who was an utter stranger to him, was at the time engaged in talking to some friends, his back being turned to the prisoner. The man suddenly seized a poker and struck the inspector a violent blow on the skull, from which he speedily died. The prisoner admitted that he struck the blow; that he had no motive for the act; and that he would have struck any one else who had been standing there at the time. He also said he hoped the deceased would die; he was glad he had done it, and he wished to be hanged. The evidence at the trial showed that there was no cause of quarrel between the parties, but that the prisoner appeared to be actuated by some sudden impulse, for which not the slightest reason could be assigned. This man was left to a chance defence, for the Court was actually obliged to assign counsel to him. There was no eloquent advocate, to make a brilliant and touching speech in his favour; there were no medical witnesses profoundly versed in psychology.
THE PLEA OF INSANITY.

931

to contend for the existence of a “homicidal climax,” or of impulsive homicidal monomania; but there was simply a formal plea of insanity, resting upon the fact of the deceased being a stranger to the prisoner, and of there being, consequently, no motive for the act of murder. The jury negatived this plea, and the prisoner was convicted and executed! The differences between this case and that of *McNaughten*, were, that there was in *Lawrence* less evidence of deliberation, with stronger evidence of sudden and irrational impulse; and there was not sufficient interest about the deceased, the prisoner or his crime, to attract any great public attention!

This case had not long occurred, when another of a similar kind was the subject of a trial at the Central Criminal Court (*Reg. v. Hon. Ross Touchett*, October 1844). The prisoner, a young man, entered a shooting gallery in Holborn, took up a pistol, and deliberately fired at the proprietor of the gallery while his back was turned, thereby inflicting a wound which ultimately led to his death after the long period of eleven months. The prisoner was tried for shooting with intent to murder. The defence was insanity, founded on the absence of motive for the act and on the presumption of hereditary taint. After having fired the pistol the prisoner said he did it on purpose, for he wished to be hanged. This was no evidence of *intellecutal aberration*: his landlord said he was a very regular and quiet person, and that he had complained of a sensation of boiling at the top of his head! Dr. Monro considered that at the time of the act the prisoner was labouring under mental derangement. The prisoner admitted to him that he had no knowledge of Mr. Smith (the person whom he shot), but that he wished to be hanged, and had been brooding over suicide for some years. He referred to the case of *Lawrence*, who had killed a man at Brighton (supra), and said that he wished to do something of the same kind, in order to get himself hanged. He was acquitted on the ground of insanity. What distinction can possibly be made by physician or jurist between these two cases,—or how is it possible to lay down rules for the future guidance of medical witnesses under such capricious verdicts as these? The acquittal of *Touchett* may have been perfectly right; but then the conviction and the execution of *Lawrence* was a public wrong. Again, it would be difficult to reconcile, upon medical, moral, or legal grounds, the conviction of *Francis* with the acquittal of *Oxford*, both of them tried for the same crime (shooting at the Queen), committed under similar circumstances. In the case of *Reg. v. Stolzer* (Cent. Crim. Court, Oct. 1843), where the charge was one of murder by stabbing, the plea was rejected, although no motive appeared, and there were some indications of insanity. In another case (*Reg. v. Rowe*), tried at the same time, the prisoner an old man, deliberately fired a loaded pistol at his master,
because he had did not take him back. the act or in the matter as insane, on the law under the imbecility.

When the punishment it would appear that to establish a plea of This will be seen by the Ford Lent Assizes, 1 considerably stronger than yet the prisoner was closely to each other upon the reception of it.

That this kind of was apparent from an observe of Rex. v. Reynolds in defence of insanity life security of the public also Mr. Justice Con marked, “that the be watched with constant slight deviation from case under a given is such a line of defence to simply because appear in the evidence.”

It cannot be denied it has been strained in justifiable distrust of It is obviously easy to infer of all kinds of crim thus medical wit
perfect justification of every crime that was committed. What
was the meaning of not being able to resist an impulse? Every
crime was committed under an impulse, and the object of the
law was to compel persons to control these impulses. If it was
made an excuse for a person who had committed a crime, that
he had been goaded to it by some impulse, which medical men
might choose to say he could not control, he must observe that
such a doctrine would be fraught with very great danger to
society."

Among recent cases deserving of notice are the following:—
In Reg. v. Adams (Maidstone Summer Assizes, 1856), the pri-
soner was indicted for cutting and wounding her infant child
aged four months. It was proved that she was a quiet, harm-
less woman: there was no motive for the act, and when asked
why she had done it, she said she had had an intention to do
it for a fortnight, and that for three or four nights she had been
unable to sleep in consequence of thinking about it; and at last
she had done it. She was out of health at the time, and the
medical evidence was to the effect that she was probably suffering
from some morbid action of the brain when she committed the
act. There was no evidence of intellectual insanity. Erle J.
considered that the prisoner was not criminally responsible on
account of the state of her mind, and a verdict of Not Guilty
was returned on the ground of insanity. The case of Dedea
Redanies (Maidstone Winter Assizes, 1856) called forth this plea,
appearently because there was no other point on which a defence
could possibly turn. The prisoner inveigled two girls from their
home under false pretences, and murdered them, by stabbing
them deliberately, one after the other, on the high road. He had
admitted that he had destroyed them, and no motive could be
suggested but a morbid and unfounded feeling of jealousy. The
acts and correspondence of this man before and subsequently to
his conviction were such as to convey an idea that he was in
some degree insane. Still there was no evidence that his insanity
had reached a degree to justify his acquittal on this ground, and
his conviction and punishment may fairly operate by preventing
others, labouring under like morbid feelings, from indulging in a
propensity to destroy life. The case of Buranelli (Reg. v. Buranelli,
Cent. Crim. Court, April 1855), also a charge of deliberate assas-
sination, created some difference of opinion in reference to this
plea. Dr. Conolly considered the prisoner's mind to be in an
unsound state, while Drs. Mayo and Sutherland deposed that
there was no unsoundness, and that the man was a hypochond-
driac rather than a lunatic. The crime was committed under
circumstances which in my opinion fully warranted a conviction
for murder. Absurdities of conduct or conversation are not of
themselves sufficient to justify an acquittal on the ground of in-
sanity. Even admitting that the acts adduced in evidence were
not those of a person of reasonable mind, this, as it has been else-
where stated, is not legally sufficient to justify an acquittal. The
insanity must have reached such a degree as to overpower the
mind or will, and when this is not proved, no case is made out
for exculpation.

The legal test of a knowledge of the nature of the crime, or of
right and wrong, is undoubtedly (see ante p. 918) the principal
cause of inconsistent and even conflicting verdicts. The case
of Reg. v Westron, (Cent. Crim. Court, Feb. 1856,) furnishes
a curious illustration of this. The prisoner was charged with
the murder of a Mr. Waugh, a solicitor. On some provoca-
tion partly real, and partly based on an exaggerated view of
his rights, the prisoner shot the deceased in open day in a public
thoroughfare. The only question therefore for the jury was
the state of mind of the prisoner. It was proved that he
was ill-tempered and violent about trifles; but he had an acute
knowledge of business, and lived by himself in various lodg-
ings. The persons with whom he had lived, deposed that his
conduct was so strange and unreasonable at times, that they
were glad to get rid of him as a lodger. Evidence was also
given to the effect that several members of his family had been
insane, and that the prisoner himself three years before had
suffered from mental excitement, but it was not such as to render restraint necessary. The medical witnesses declined to
say in answer to questions put by the learned judge and counsel
—that the prisoner was in such a state of mind as to be incapable
of knowing that the act of killing a man was wrong. Dr. Synnot
properly observed, that many lunatics would be aware, perfectly
well, that the act was a wrong one. On this it was contended
for the prosecution, that as the prisoner was perfectly aware of
what he was doing, he was therefore fully responsible. The
jury were as usual directed to decide whether the prisoner was
proved to have been in such a state of mind at the time the act
was committed, that he did not know the nature and quality of
the act, or of the distinction between right and wrong. Of
course upon the medical evidence the jury had no option but to
find the prisoner guilty of wilful murder, but they recommended
him to mercy on account of his strong predisposition to insanity.
This verdict was tantamount to Not Guilty on the ground of
insanity. Sentence of death was therefore simply recorded.
With such a verdict the learned judges appear to have felt that
the usual punishment of death for wilful murder could not be
carried out. The jury were bewildered by the test submitted
to them. They appear to have considered the man insane, but
that his insanity had not reached the legal standard of an
absence of knowledge of right and wrong. The general history
of the prisoner and his crime tended to show insanity: but
there was no reason to believe that it had reached that point
at which there is a loss of all knowledge of the nature and quality of the act perpetrated. On the contrary, the deceased was deliberately shot by the prisoner, out of revenge for a supposed injury. His whole conduct showed that he knew the act was illegal, but he set the law at defiance. A man actuated by mere brutal recklessness could have done no more.

The theory of the law as laid down by the judges in McNaughten's case is, that notwithstanding a person labours under delusions, if he commits an act which he knows to be contrary to law, he is liable to punishment (ante, page 918). But as Dr. Mayo observes, the very case which elicited this answer (Reg. v. McNaughten), proves that the practice is not in accordance with the theory. "The adequacy of McNaughten to comprehend the criminal nature of the homicidal act for which he was tried was unquestionable, yet he was acquitted on the plea of insanity, without the smallest reference to the conditions on which alone it is exculpatory, although they had been distinctly set forth as not complied with, in the opening speech of the Attorney-General. The prisoner was pronounced to be insane by several medical witnesses, and on this evidence the learned judge stopped the case, and directed an acquittal, without going into the question whether the prisoner was, or was not, ignorant of the illegal nature of the act. In his address to the jury, he used the ambiguous expressions of knowledge of "right and wrong"—not "legal and illegal," as absent in McNaughten's mind. (Medical Testimony, p. 86) The terms "right and wrong," thus used, are certainly vague and undefined. If that which is legal is right, and that which is illegal is wrong, it would be only proper to discard the words, "of a knowledge of right and wrong," and place the question before the jury in accordance with the answers given by the judges in McNaughten's case—namely: whether the prisoner knew at the time of committing the act that it was illegal. But the verdicts in this and other cases, prove that the law does not and cannot act rigorously upon this doctrine.

The following cases may be consulted with interest in reference to this subject. Reg. v. Johnstone (Med. Gaz. xxxvii. p. 421); Reg. v. Ovenston (Journal of Psychol. Med. 1848, p. 169); Reg. v. Allnutt (Journal Psychol. Med. 1848, p. 193); and Reg. v. Brough, Guilford Summer Assizes, 1854. (Journal Psychological Medicine, 1854, p. 609.) In the two first the prisoners were acquitted on the ground of insanity; although I quite agree with Dr. Mayo, in thinking that in Johnstone's case there was not the slightest proof of insanity. (Clinical Facts, 208.) The reader will find other cases in Med. Gaz. xlii. p. 255; and Reg. v. Clarke, Norfolk Lent Assizes, 1851; Reg. v. Monkhouse, Cent. Crim. Court. Dec. 1849; Reg. v. Arnold, Aylesbury Lent Assizes, 1850; and Reg. v. Butter, Shrewsbury Summer Assizes, 1853. In
SUICIDAL MANIA.

Mayo's Clinical Facts, 1847, p. 193; Croonian Lectures, Med. Times and Gaz. 1853; also Medical Testimony, 1854: in the Lec-
somian Lectures of Dr. F. Winslow, Lancet, June 1853; Med.
in essays on Unsoundness of Mind in reference to Responsi-
bility, by Mr. Knaggs, 1854, by Dr. Bucknill on Unsoundness of
Mind in relation to Criminal Acts, 1854, and by Mr. F. Stepon the Criminal Responsibility of Madmen (Juridical Papers,
vol. i. p. 67).

The principles of the English law have been closely scrutinised
by men who have had long experience in the management of the
insane, and who have made themselves well acquainted with their
habits; and it has been abundantly proved, that the test of re-
sponsibility assumed by it is of a purely theoretical kind, and
cannot be carried into practice. With this admission it appears
to me unnecessary to occupy space with metaphysical discus-
sions regarding criminal responsibility; for however defective the rules
if the practice of the law be in any one case in conformity with
that which has been advised by writers on the medical jurispru-
dence of insanity, although it may be adverse to the theory on
which it is professedly based, this is all with which we have to
concern ourselves:—the principle is admitted. The great defect
in the English law is, not that it will not go even to the full
extent of exculpating a person who has committed a crime under
what is called an "uncontrollable impulse," or an impulse which
his reason was not sufficient to control (cases of Greensmith, ante.
p. 925, Touchett, ante, p. 931), but the uncertainty of its applica-
tion (case of Laurence, ante, p. 930). The cases referred to show,
that an acquittal on the plea of insanity is on some occasions a
mere matter of accident.

CHAPTER LXX.

AND CRIMINAL LIABILITIES OF THE DEAF AND DUMB.

SUICIDAL MANIA.

Suicide not necessarily indicative of insanity. — In monomania,
especially in that form which is called melancholia or lypemania,
there is often a strong propensity to the commission of suicide.
This may proceed from sudden impulse or delusive reasoning.
Suicidal mania is susceptible of being spread by imitation,
especially when the mode of self-destruction adopted is accom-
panied by circumstances of a horrible kind, or exciting great
notoriety. The sight of a weapon or of a particular spot where a
previous suicide has been committed, will often induce a person,
who may hitherto have been unsuspected of any such disposition,
at once to destroy himself. In some instances an individual
fancies that he is oppressed and persecuted, that his prospects in
life are ruined, when, on the contrary, his affairs are known to be
flourishing. He destroys himself under this delusion. In cases
of this description, whether arising from a momentary insane
impulse or from delusive reasoning, there cannot be a doubt that
the act is one of insanity. It is very different, however, where a
real motive is obviously present,—as when an individual destroys
himself to avoid disgrace or impending ruin, because here the
results are clearly foreseen, and the suicide calculates that the loss
of life would be a smaller evil to him than the loss of honour and
fortune. It may be urged that a motive of this kind will appear
insufficient to the minds of most men;—but what known motive
is there sufficient to account for parricide, infanticide, or any other
crime of the like horrible nature? It appears to me, we must al-
low either that all crime is the offspring of insanity, or that suicide
is occasionally the deliberate act of a sane person. To say that
suicide is always per se evidence of insanity, is to say substantially
that there is no criminality in self-murder; for it is impossible to
regard that act as a crime, which is committed under a really
insane delusion. (See Ann. d’Hyg. 1831, i. 225.) For some
remarks on this subject, see Lectures by Dr. Jamieson, Med. Gaz.

Suicide a felony.—The law of England very properly treats
suicide as a felony; those who have attempted and failed in its
perpetration are held to be sane and responsible agents, unless
there should be clear evidence of their (intellectual) insanity
from other circumstances; and it is pretty certain, that the evidence
required to establish this must be much stronger than that
sometimes admitted in cases of homicide. Thus, had Oxford and
McNaughten attempted to destroy themselves and failed, and in
making the attempt on their own lives by a pistol or otherwise,
had accidentally led to the death of a bystander, and had after-
wards been tried for the felony, it is highly probable that they
would have been convicted. The hypothesis of a suicidal climax
would have been rejected. The facts adduced at their trials
would, under these circumstances, have been deemed insufficient
to establish their insanity and consequent irresponsibility for the
attempts on their own lives.

Some singular medico-legal cases have occurred, involving the
question—how far the act of attempting suicide is indicative of
insanity. In the case of the Queen v. Rumball, (Cent. Crim. Court,
May 1843,) the prisoner was charged with attempting to drown
her child. It appeared in evidence, that she fastened her child to her dress, and threw herself into a canal with the intention of destroying herself. She was rescued, and was subsequently tried and convicted of the felony of attempting to murder her child by drowning. Had she not been rescued, and had she succeeded in her purpose of self-destruction, it is probable that the verdict of a jury would have been, as it so frequently is on these occasions,—“Temporary insanity.” In the case of Reg. v. Furley, (Cent. Crim. Court, April 1844,) the prisoner was convicted of murder under similar circumstances, but the sentence was subsequently commuted. In the case of Reg. v. Gathercole, 1833, a man was charged with the manslaughter of the deceased, under the following singular circumstances. The prisoner threw himself into a canal for the purpose of drowning himself; the deceased, who was passing, jumped in and rescued him; but by some accident he was himself drowned in the humane attempt. The defence was, that the prisoner was at the time insane, and therefore not responsible for the death of the person who attempted to save him; but this was negatived, and the prisoner was convicted. So if a man intending to shoot himself, fails, and by accident shoots a bystander, he will be held responsible, unless there be clear proof of insanity:—the act—the attempt itself, taken alone, will not be admitted as evidence.

Suicide in relation to life-insurance.—It is well known that according to the rules of many English Offices a policy of life-insurance is forfeited by the act of suicide; but supposing it to have been really an act of insanity, it has been doubted whether the policy would be legally forfeited. In an equitable view, the policy should not be forfeited under these circumstances, any more than if the party had died accidentally by his own hand. The condition truly implies that the party puts himself to death deliberately, and not unconscious, while labouring under a fit of delirium or insanity. The question was raised in the case of Borradaile v. Hunter (Dec. 1841). This was an action brought to recover the amount of a policy of insurance effected on the life of a clergyman who threw himself into the Thames from Vauxhall Bridge, and was drowned. The whole case turned upon the legal meaning of the words “die by his own hand,” which formed the exception in the proviso to the payment of the policy. At the trial of the case, Erskine J. directed the jury, that if the deceased threw himself into the river, knowing that he should destroy himself and intending to do so, the policy would be void:—they had further to consider whether the deceased was capable of distinguishing between right and wrong at the time, or, in other words, whether he had a sufficient knowledge of the consequences of the act to make him a felo-de-se. The jury found that the deceased threw himself into the water intending to destroy himself, and that previously to that time there was no
evidence of insanity. They were then directed to take the act itself, with the previous conduct of the deceased, into consideration, and say whether they thought, at the time, he was capable of knowing right from wrong. They then found that he threw himself from the bridge with the intention of destroying himself, but that he was not then capable of judging between right and wrong.

The jury were here evidently perplexed with the strict meaning of the words right and wrong:—the first part of the verdict made the case one of felo-de-se, the last part made it one of insanity.

The verdict was entered for the defendants; i.e. that the deceased was a felo-de-se, and that the policy was therefore void.

The case was subsequently argued before the four judges in the Common Pleas (May 1843): it was contended for the plaintiff that according to the terms of the policy there must have been an intention by the party assured, to "die by his own hands;" and that an insane person could have no controllable intention. The judges differed:—three thought that there was no ground for saying that the deceased was affected by an uncontrollable impulse,—on the contrary, the jury had found that he threw himself into the river, knowing that he should destroy himself and intending to do so. In their opinion, the act was one of felo-de-se, and the policy was void. Tindal C. J. considered, that the verdict should be for the plaintiff, thereby leading to the inference that the act of suicide was in this case the result of insanity, and not of a felonious killing, to which alone he considered the exception in the proviso should apply. It is probable that if the term "suicide" had been inserted in the policy, instead of "die by his own hand," the decision would have been in favour of the plaintiffs; for to vitiate a policy from an accidental result depending on an attack of insanity, and flowing directly from that attack, is virtually vitiating it for the insanity itself! In this respect, it appears that the learned Chief Justice took a most sound and equitable view of this question, so important to the interests of those who have insured their lives. It is impossible for a man to enter into a contract against an attack of insanity, any more than against an attack of apoplexy! The jury found that the deceased was irresponsible for the act, and it is clear that the insurers and insured intended no more by using the terms "die by his own hand," than the act of suicide. By this decision, therefore, the insurers received the benefit of a wider interpretation of the terms than that which either party could have foreseen.

The question was again raised in the case of Schwabe v. Clift, Liverpool Summer Assizes, 1845. (Med. Gaz. xxxvi. 826.) The deceased, whose life was insured, destroyed himself by taking sulphuric acid. There was clear evidence of his being at the time in a state of insanity. The jury here, under the direction of Cresswell J., took a proper view of the subject, and re-
turned a verdict for the plaintiffs, thereby deciding that the policy was not vitiated by the mere act of suicide. The learned judge held that to bring the case within the terms of the exception, the party taking his own life must have been an accurate moral agent, and able to distinguish right from wrong. In this case, the term "suicide" was used in the policy, which the learned judge held to imply "a felonious killing." Supposing that the insured party was killed by voluntarily precipitating himself from a window while in a fit of delirium from fever, this would be an act of suicide or dying by his own hand; but it surely cannot be equitably contended that his heirs should lose the benefit of the insurance in consequence of an event depending on an accidental attack of a disease which no one could have foreseen, and against which no one could guard. If this principle be not admitted, the decision which must necessarily follow would appear to be against all equity; if it be admitted, then it must apply equally to every case of mental disorder, the proof of the existence of this resting with those who would benefit by the policy. On an appeal, the judgment in this case was, however, reversed, the judges again differing. It was argued for the insurers, that if a man retained just enough of intelligence to produce death by competent means, but was deprived of all moral sense, the policy was void. Against this view, it was urged by one of the judges, that whether the intellect was destroyed altogether, or only partially, it could make no difference. If death was the result of disease, whether by affecting the senses or by affecting the reason (thus leading to suicide), the Insurance-office was liable under the policy. If the act was not the act of a sane and reasonable creature, it was not an act of suicide within the meaning of the proviso. Those judges who adopted the opposite view held that the meaning of the words, as introduced into the exception, was—if the party should kill himself intentionally. The words were considered to include all cases of voluntary self-destruction. If a party voluntarily killed himself, it was of no consequence whether he was sane or not. The majority of the Court held this view, and a new trial was granted. Had all the judges been present to give their opinions, the decision might have been different, for five had expressed themselves, at various times, in favour of the view that the term "suicide" in policies, applies, as it ought to do, only to cases in which there is no evidence of insanity; while four had declared their opinion to be, that it includes all cases of "intentional" self-killing, whether the person be sane or insane. It is difficult to understand how a man in a fit of delirium or insanity can be said to kill himself voluntarily or intentionally. Will and intention imply the judgment of a sane man in regard to all civil and criminal acts; but a delirious or really insane person acts under a delusion, and as the law would hold him
irresponsible in regard to others, his representatives should not suffer for an act which he was himself incapable of controlling. (Law Times, July 18, 1845, p. 342.)

The decision in this case is of great importance to persons whose lives are insured; for it may be made to govern others; and on this principle, a man attacked with delirium, and who during the fit precipitated himself from a window, and was killed, would be declared a suicide within the meaning of the proviso, and a policy of insurance on his life would be ipso facto void. It will be perceived from this decision, that the law, as at present interpreted by the majority of the judges, is, that whenever a person destroys himself intentionally, whatever may be the state of his mind, the policy becomes void. It also appears that according to this legal view of the question, a person may have and exercise this intention although undoubtedly insane. Whether he have been so found under a commission, or a verdict to this effect have been returned by a coroner’s jury, is therefore unimportant. It must be proved by those who would benefit by the policy that the party died from his own act without intending to destroy himself. If a man take poison, or shoot himself, or commit any other act leading to his own death, it must be shown that it was the result of accident, and not of design on his part. Some Insurance-offices now insert in the contract a proviso by which, whether the person be found felo-de-se or not, the policy shall be forfeited: but they reserve to themselves a power of returning a part or the whole value of the policy, calculated up to the day of death. In the meantime, they have the power of taking the full benefit of an act of suicide committed during a fit of delirium or insanity, in which, as medical men know, there can exist no controllable intention, no freedom of judgment, and no real exercise of will. (See case, Prov. Med. Jour. Aug. 9, 1848, 428.) There is a form of suicide not unlikely to present itself for consideration, namely, where a man in the habit of taking a powerful drug for medicinal purposes, takes a large dose while in a state of intoxication and dies. In May 1857 a Mr. George Fife died from an overdose of morphia, and it was proved, to the satisfaction of the jury, that this must have been taken while he was intoxicated. In such a case a man may have no sane intention of destroying himself, yet he dies by his own hands. As drunkenness does not excuse or justify any act of homicide, so it would not probably be allowed to affect the question of suicide, and death under such circumstances would probably be held to be a felonious killing.

From these cases one point is clear,—the act of suicide is not treated by the law, as a necessary proof of insanity; and, therefore, the ingenious arguments which have been held on this subject have but little interest for a medical jurist in a practical view. It has been elsewhere stated, that acts of suicide have been mis-
A homicidal propensity towards their offspring sometimes manifests itself in women soon after parturition. It seldom appears before the third day, often not for a fortnight, and in some instances not until several weeks after delivery. The most frequent period is at or about the commencement of lactation, and between that and the cessation of the discharges (lochia). According to Esquiriel, it is generally attended by a suppression of the lochia and milk. The late Dr. Ashwell remarked, that undue lactation may give rise to an attack of mania, under which the murder of the offspring may be also perpetrated. (Diseases of Women, 732.) The symptoms do not differ from those of mania generally; but it may assume any of the other forms of insanity; and in one half of the cases it may be traced to hereditary tendency. According to Dr. Burrows, there is delirium, with a childish disposition for harmless mischief. The woman is gay and joyous, laughing, singing, loquacious, inclined to talk obscenely, and careless of everything around. She imagines that her food is poisoned; she may conceal the suspicion, and merely avoid taking what is offered to her. She can recognise persons and things, and can, though perhaps will not, answer direct questions. Occasionally there is great depression of spirits with melancholia. These facts are of some importance in cases of alleged child-murder. This state may last a few hours, or for some days or weeks. The murder of the child is generally either the result of a sudden fit of delirium, or a sudden impulse, with a full knowledge of the wickedness and illegality of the act,—so that the legal test of responsibility of a knowledge of right and wrong cannot be applied to such cases, except on the assumption that insanity already exists, and taints the consciousness of the individual. Mothers have been known, before the perpetration of the murder, to request their attendants to remove the child. Such cases are commonly distinguished from deliberate infanticide, by there being no attempt at concealment, nor any denial of the crime on detection. Several trials involving a question of puerperal mania, have been decided, generally in favour of the plea, within the last few years. Among the latest of these is that of Reg. v. Ryder, C. C. C., March 1856. There was an entire absence of motive in this as in most other cases of a similar kind. The mother was much attached to the child, and had been singing and playing with it on the morning of its death. She destroyed the child by placing it in a pan of water in her bedroom. The medical evidence proved that she had been delivered about a fortnight previously; that she had had an attack of fever, and that she had probably committed this act while in a state of delirium. She was acquitted on the ground of insanity, and Erle J. remarked that, as it was evidently a case where the insanity
was only temporary, the prisoner might be restored to her friends on a representation being made in the proper quarter. In most of these cases it will be found that the females are fully aware of the nature of the act, and that it is contrary to the laws of God and man; but they are unable to control their actions like sane persons.

Females in the pregnant state have been known to perpetrate murder apparently from some sudden perversion of their moral feelings: there has no doubt been latent intellectual disturbance, but not sufficient to attract the notice of friends. I am not aware that a plea of exculpation on the ground of insanity has been admitted in this country under these circumstances. (See case, Am. d'Hyg. 1831, i. 374.) For an able analysis of the present state of our knowledge on the subject of Puerperal Insanity, by Dr. Reid, see Jour. Psychol. Med. 1848, pp. 128, 284.

PYROMANIA.

Propensity to incendiarism.—This is described as a variety of monomania in which there is a morbid disposition of mind, leading to acts of incendiarism without any motive. It is a condition not specially recognised by the law of England. We are informed by the advocates of its independent existence, that it proceeds from sudden impulse, or from delusive reasoning, but most commonly the latter. It has been chiefly remarked in females about the age of puberty, and is supposed to be connected with disordered menstruation. The case of Jonathan Martin has been frequently quoted as an instance of pyromania. He had, however, merely a delusion that he was deputed by God to burn down the cathedral of York, in order to do away with the heresies which he supposed to exist in the church. The defence, as in most of these cases, was insanity at the time of perpetrating the act, and not specially Pyromania. This so-called mania is said to be not uncommon in young persons of both sexes, about the age of puberty. Assuming that a morbid impulse of the kind may exist, it should be very cautiously received as an exculpatory plea, since otherwise it might be easily converted into a means for withdrawing real criminals from all legal control: and I would here especially direct the attention of the reader to an essay on this subject by Professor Casper, of Berlin, in which he denies, with great probability, the existence of such a propensity as having any connection with insanity. He believes that incendiarism is always a criminal act, and unless there be clear evidence of a perverted mind, that it should be always punished as such. (Dankwürdigkeiten zur Med. Stat. Berlin, 1846, 255.) The plea has been admitted in English law (see cases, Med. Gaz. xii. 80), but only in those instances in which there was strong reason to suspect intellectual aberration. In one case (Reg. v. White, Wilts Sum. Ass. 1846), the prisoner was convicted on the principle that,
although of weak intellect, she had reason enough to know right from wrong. (See Ann. d’Hyg. 1833, ii. 357; 1834, ii. 94). Among several important trials in which a plea of insanity has been urged in defence in cases of arson, is that of James Gibson, tried before the High Court of Justiciary, Edinburgh (Dec. 23, 1844), and of which a full report will be found in Vol. Pt. 4, of Brown’s Reports of Cases before the High Court, 1845, p. 332. The prisoner was charged with setting fire to certain premises and the defence chiefly rested upon the allegation, that he was in a state of mind which rendered him irresponsible for the act. Medical evidence was adduced in support of this proposition; but it failed to show that the insanity, if it existed, had reached such a degree as to render the accused irresponsible, and it did not appear that the circumstances on which the medical witnesses relied as proofs of insanity, had manifested themselves until after the perpetration of the crime with which he was charged. The prisoner was very properly convicted, and sentenced to transportation for fourteen years. There was nothing in his case to justify a remission of the usual punishment assigned to this crime. Although this case is here noticed under the section of Pyromania, yet strictly speaking the defence turned rather upon the alleged existence of general insanity than upon that form of it in which the insanity is supposed to be attended with a propensity to incendiaryism. The Lord Justice Clerk Hope directed the jury to deal with this case according to the views laid down by the judges of England, and elsewhere quoted (ante, p. 918). He considered that the insanity to be proved as a ground of exemption must be total; i.e. “the disorder must amount to an absolute alienation of reason. * * * No such principle is recognised in law as that a man allowing a fancy or morbid feeling to get possession of his mind and temper, although it disturbs reason, while it does not overthrow it, will escape punishment, because, instead of resisting the temptations of such ill regulated, morbid, dis tempered, and ungovernable feelings and prejudices (whether called delusions or not), he gives way to them and indulges in their gratification and satisfaction.” These remarks, it will be seen, apply to the plea of insanity in general, and the learned judge further remarks, with respect to the knowledge of right and wrong: “A man must believe not that the crime is wrong in the abstract (for most madmen do admit murder to be wrong and punishable in the abstract,) but that the particular act, committed under the influence of the motive which seems to have prompted it, was not an offence against the law. One may know that in the abstract the act is punishable, and yet believe that his particular act is not in law a crime and not punishable.” From these extracts it will be perceived, that the law of Scotland, in reference to the plea of insanity in criminal cases, is substantially the same as that of England. In the case of Reg. v. Eldersfield, (Guildford
Summer Ass. 1844,) the prisoner was charged with arson, and Gurney, B., left it to the jury to say, not whether the prisoner had a weak or silly mind, but whether, at the time he committed the act, he was in such a state of mind as to know what he was about, and to be capable of distinguishing between right and wrong. The prisoner was acquitted on the ground of insanity. In another case (Reg. v. Watts, Norwich Winter Ass. 1844), the plea was negatived under the direction of the judge.

**KLEPTOMANIA.**

*Propensity for theft.*—This term has been applied by Marx to that form of monomania which is said to manifest itself by a propensity to acts of theft. It is alleged by him and others that this propensity has often shown itself in females labouring under disordered menstruation, or among those who were far advanced in pregnancy, the motive being the mere wish of possession. Pregnancy, according to him, should be a good exculpatory plea, when a well-educated woman, of strictly moral conduct, steals some unimportant article of no value compared with her worldly means and position in society. There are several instances on record showing that well-educated persons moving in a respectable sphere of society have been guilty of petty acts of theft. The articles taken have been valueless compared with their means. Instances of this kind have been brought before our Police-courts: and this motiveless impulse to theft has been occasionally pleaded: but in most of them the following facts have been clearly established by evidence:—1. A perfect consciousness of the act and of its illegality. 2. The article, though of trifling value, has still been of some use to the person,—thus these females have stolen articles only adapted to female use. 3. There have been art and precaution in endeavouring to conceal the theft; and 4. either a denial of the act when detected, or some evasive excuse. When circumstances of this kind are proved, either the parties should be made responsible, or theft should be openly tolerated. The evidence of a disordered state of the mind should not here be allowed to depend on the nature of the act, or every morally depraved person might bring forward a plea of insanity for any crime or offence. (See case, Ann. d'Hyg. 1838, ii. 435.) When the plea of insanity is raised in respect to other cases of theft, the rule appears to be, per Tindal C. J., that there should be proof that the prisoner was incompetent to know that the particular act in question was a wrong one. (Reg. v. Vaughan, Monmouth Summer Ass. 1844.) In one instance, an acquittal took place apparently on the ground of insanity (kleptomania) from amenorrhœa. (Carlisle Summ. Ass. 1843, Reg. v. Shepherd.) Cormack's Ed. J. Aug. 1845, p. 632.
Responsibility of Drunkards.

Dipsomania. Drunkenness.

Civil responsibility of drunkards.—This state, which is called in law, frenzy, or "dementia affectata," is regarded as a temporary form of insanity. Jurists and legislators have differed widely respecting the degree to which drunkards should be made responsible for their acts. When the mind of a man is completely weakened by habitual drunkenness, then the law infers irresponsibility, unless it plainly appear that the person was at the time of the act, whether of a civil or of a criminal nature, endowed with full consciousness and reason to know its good or evil tendency. Any deed or agreement made by a party when drunk is not invalidated by our law, except in the case in which the intoxication has proceeded so far as to deprive him of all consciousness of what he is doing; and a court of equity will not interfere in other cases, unless the drunkenness were the result of collusion by others for the purposes of fraud. When the drunkenness has occasioned a temporary loss of the reasoning powers, the party is incapable of giving a valid consent, and, therefore, cannot enter into a contract or agreement, for this implies aggregatio mentium, i.e. a mutual assent of the parties. Partial drunkenness, therefore, provided the person knew what he was about, does not vitiate a contract or agreement into which he may have entered. Thus the law appears to create two states in drunkenness:—one in which it has proceeded to but a slight extent, and it is considered that there is still a power of rational consent; another in which it has proceeded so far that the person has no consciousness of the transaction, and therefore can give no rational consent. The proof of the existence of this last state would vitiate all the civil acts of a party. A confession made by a man while in a state of drunkenness, is legally admissible as evidence against him and others, provided it be corroborated by circumstances. In a case tried a few years since, the prisoner confessed, while drunk, that he had committed a robbery and murder which had taken place some time before, but of which he had not been suspected. He mentioned a spot where the property of the murdered person had been concealed by him, and the whole of the circumstances of the murder. The property was found as he had described it, and the case was clearly brought home to him, chiefly by collateral evidence from his own confession. He was convicted. In a case tried at the Central Criminal Court, in Oct. 1849, a man pleaded his drunkenness at the time of his first marriage, as a defence to a charge of bigamy. There was some evidence to show that he was drunk when the ceremony was performed. He was, however, convicted. (Med. Gaz. xliv. p. 762.)

Criminal responsibility of drunkards.—When homicide is committed by a man in a state of drunkenness, this is held to be no
excuse for the crime. If voluntarily induced, whatever may be its degree, it is not admitted as a ground of irresponsibility, even although the party might not have contemplated the crime when sober. (Reg. v. Reeves, Derby Winter Assizes, 1844.) Thus it appears that when the state of drunkenness is such that any civil act of the person would be void, he may still be held legally responsible for a crime like murder. Some judges have admitted a plea of exculpation, when the crime has been committed in a state of frenzy arising from habitual drunkenness; but even that is not general. The question, whether the person was or was not drunk at the time of committing a crime, may be, however, occasionally of some importance. It was held by Patterson J., that although drunkenness is no excuse for any crime whatever, yet it is of very great importance in cases in which there is a question of intention. A person may be so drunk as to be utterly unable to form any intention at all, and yet he may be guilty of very great violence. (Reg. v. Cruse, 8 C. & P. 546.) Again, when it is a question whether the accused was actuated by malice or not, the jury may under certain circumstances be required to take the fact of drunkenness into consideration, and this may have an influence upon their verdict. While, then, drunkenness does not furnish any excuse for a crime, it may become material with reference to the intent with which an act has been perpetrated. (Law Times, Sept. 27, 1845, p. 542.) It is obvious that if drunkenness were to be readily admitted as a plea of irresponsibility, three-fourths of the whole of the crimes in the country would go unpunished. In those cases in which the body has sustained any physical injury, as it often happens with soldiers and sailors, drunkenness, even when existing to a slight extent, produces sometimes a fit of temporary insanity, leaving the mind clear when the drunken fit is over. The law makes no distinction between this state and ordinary drunkenness, although juries occasionally show by their verdicts that some difference ought to be made. (See cases in Alison, 653.)

Illusions.—Hallucinations and illusions are a very common effect of drunkenness, and often lead to the commission of criminal acts. More relates a case, where two friends being intoxicated, the one killed the other under an illusion that he was an evil spirit. The drunkenness of the accused was held to have been voluntary; and he was condemned to ten years' imprisonment with hard labour. A case of this description was tried at the Norfolk Lent Assizes, 1840. (Reg. v. Patterson.) A man while intoxicated killed his friend, who was also intoxicated, under the illusion that he was some other person who had come to attack him. The judge made the guilt of the prisoner to rest upon whether, had he been sober, he would have perpetrated the act under a similar illusion! As he had voluntarily brought himself into a state of intoxication, this was no justification. He
was found guilty of manslaughter, and sentenced to two months' imprisonment.

The proof of drunkenness may fail, but still, if the party charged with the death, acted under an illusion he will be acquitted. In the case of Reg. v. Price (Maidstone Summer Ass. 1846), it was proved that the prisoner who had been on friendly terms with the deceased, was going home at night, having previously been in company with the deceased, at a public-house, when, according to his statement, a man sprang upon him from the hedge by the road-side, and demanded his money and his watch, or else he said he would have his life: the prisoner closed with and beat him severely, inflicting such injuries that he died very shortly afterwards. The supposed robber turned out to be the deceased, and it was believed that he had made an attempt to rob the prisoner jokingly, which, however, ended in this fatal manner. The prisoner throughout told the same story, and there did not appear to be the slightest ground for believing that it was untrue. Coltman J., after hearing the evidence of the witnesses, said it appeared to be quite clear that the prisoner had acted under the impression that he was protecting his own life from the attack of a robber, and under such circumstances he could not be held to be criminally responsible. The jury accordingly returned a verdict of not guilty, and the prisoner was discharged.

Restraint — Interdiction. — Drunkenness, even when habitual, is not a sufficient ground for the imposition of restraint or interdiction in the English law. Thus, on a commission in Nov. 1836, (In re Holden,) a jury returned that the party was of weak mind and given to habits of drunkenness, but that he was not of unsound mind. On application, the Lord Chancellor refused to interfere. This part of our law requires serious revision.

The case of Mrs. Armstrong, (Queen's Bench, February 1858,) presents some features of interest in reference to the alleged mental unsoundness of drunkards. The defendant, a lady, at 58, had been declared of unsound mind by a commission in August 1857. In September she escaped, and went to France: she returned to this country in January 1858, and endeavoured to set aside the verdict of unsoundness by these proceedings. It appeared that her father had bequeathed to her by his will, two thousands pounds per annum, to be paid to her monthly by trustees. The evidence at the trial showed that she was ill-educated — ignorant, and naturally of weak mind, amounting, according to some of the witnesses, to imbecility. For about ten years she had given way to habits of excessive drinking, and these habits, according to the evidence for the Crown, had still further weakened her intellect. She had been confined four times in lunatic asylums, and her unsoundness had been testified by Drs. Arnott, Conolly, Forbes Winslow, and others.
On the part of defendant, it was contended that her mind was sound, except when she gave way to drunkenness, and that by the cessation of this habit she would be perfectly sane and competent to manage herself and property. Further, that a mere drunkard could not, and ought not, to be deprived of his civil rights, unless it was proved that his mind had become permanently disturbed by his vicious habits, and this, it was urged, had not been proved of the defendant. Dr. Conolly, however, testified that although she was a year under his supervision, without any access to drink, her mind was still unsound. It appeared also that she had no control over herself in this respect: for when she escaped to France, it was proved that she still drank brandy to excess, and for a month was drunk almost daily.

Drs. Monro, Baly, Wood, and myself, saw this lady on several occasions previous to the trial, for the purpose of testing her state of mind. We found her weak-minded,—evasive,—untruthful, and although sober at the time of our visits, it was clear from her admissions, that she still drank wine and spirits in excess. She denied that she had ever been insane; and admitted that although she had hoarded £3200 in sixteen months, she had not paid her tradesmen’s bills, and had incurred a large debt at an hotel, for which an action had been brought against her husband. She refused to give any account of the disposal of her money, or to furnish any explanation in reference to the large sum accumulated.

Having heard at the trial the evidence respecting her unsoundness previous to the inquisition, and having remarked an entire absence of proof that this had been removed when she was left to her own control, Drs. Monro, Baly, and myself, came to the conclusion that from original weakness of intellect, aggravated by habits of drinking, she was of unsound mind, and incapable of taking care of herself or her property. Upon this declaration no witnesses were called for the defence; and the jury, who had had an interview with the lady, returned a verdict that she was of unsound mind,—two, out of the twelve, stating that her mind was sound, but that she was incompetent to manage her affairs on account of her habitual drunkenness. These two jurors therefore considered that she was a dipsomaniac. If this view were correct, she ought to have been discharged, as such persons are not subject to restraint or interdiction by the English law. There was no evidence to show that she had recovered, while there was evidence that abstinence from drink at a former period had not led to recovery. These dissentients must have based their opinion on their own personal judgment of her condition after a short interview.

An excessive indulgence in habits of drinking does not necessarily derange the mind: but it practically renders a person unfit for the government of himself and his property; and it is
therefore a question whether it would not be for the benefit of such persons, and those dependent on them, if the law interfered and placed them under the same restraint as those whose minds had been actually rendered unsound by this pernicious habit.

DELIRIUM TREMENS.

This is a disordered state of mind which proceeds from an abuse of intoxicating liquids. Habitual drunkenness appears to be the predisposing, while abstinence from drink is the immediately exciting cause. Thus, the disorder frequently does not show itself until the accustomed stimulus has been withdrawn for a certain period. It commences with tremors of the hands, by which it is known from ordinary delirium, and restlessness; and the individual is subject to hallucinations and illusions, sometimes of a horrible kind, referring to past occupations or events. The patients are often violent, and prone to commit suicide or murder, more commonly the former; hence they require close superintendence. Persons labouring under this disorder are incompetent to the performance of any civil act, unless the mind should clear up before death. They are not responsible for criminal acts committed while they are labouring under an attack. Acquittals have even taken place on charges of murder, when there was deliberation as well as an apparent motive for the act. Thus, then, although this disorder may have been voluntarily brought on by habitual drunkenness, the law admits it as a sufficient plea for irresponsibility; while in a case of confirmed drunkenness, it rejects the plea. In delirium there is a formed disease of the brain, while voluntary drunkenness merely produces a temporary disturbance of its functions. A trial has taken place in which the evidence showed that the homicide had been committed by an individual while labouring under an attack of delirium tremens (Reg. v. Simpson, Appleby Sum. Ass. 1845). The prisoner’s mind had become unsettled from an attack of this disorder brought on by habitual drunkenness. In another case the plea was also admitted without difficulty (Reg. v. Watson, York Winter Ass. 1845).

SOMNAMBULISM.

It has been a contested question among medical jurists, how far a person should be held responsible for a criminal act, perpetrated in that half-conscious state which exists when a person is suddenly roused from sleep. There is no doubt that the mind is at this time subject to hallucinations and illusions which may be more persistent in some persons than in others; but it is difficult to suppose, unless we imagine that there is a sudden access of insanity, that an individual should not recover from his delusion, before he could perpetrate an act like murder. A remarkable case of this description, that of Bernard Schedmaizy, will be found
in Marc (i. 56); and a trial involving this question occurred in England a few years since. A pedlar who was in the habit of walking about the country armed with a sword-stick, was awakened one evening, while lying asleep on the high road, by a man, who was accidentally passing, seizing and shaking him by the shoulders. The pedlar suddenly awoke, drew his sword, and stabbed the man, who soon afterwards died. He was tried for manslaughter. His irresponsibility was strongly urged by his counsel, on the ground that he could not have been conscious of an act perpetrated in a half-waking state. This was strengthened by the opinion of a medical witness. The prisoner was, however, found guilty. Under such circumstances, it was not unlikely that an idea had arisen in the prisoner's mind that he had been attacked by robbers, and therefore had stabbed the man in self-defence. (Reg. v. Milligan, Lincoln Aut. Assizes, 1836) The following remarkable case is quoted by Mr. Best. Two persons who had been hunting during the day slept together at night. One of them was renewing the chase in his dream, and imagining himself present at the death of the stag cried out, "I'll kill him! I'll kill him!" The other, awakened by the noise, got out of bed, and by the light of the moon, beheld the sleeper give several deadly stabs with a knife on that part of the bed which his companion had just quitted. Suppose a blow, given in this way, had proved fatal, and the two men had been shown to have quarrelled previously to retiring to rest! (Presumptions of Law and Fact.) A defence of this kind may, however, be sagaciously strained. Thus, where there is enmity, with a motive for the act of homicide, the murderer, while sleeping in the same room, may select the night for an assault, and perpetrate the act in darkness, in order the more effectually to screen himself. In the case of Reg. v. Jackson (Liverpool Autumn Ass. 1847), it was urged in defence that the prisoner who slept in the same room with the prosecutor, had stabbed him in the throat, owing to some sudden impulse, during sleep; and the case of Milligan above given was quoted by the learned counsel, in support of the view that the prisoner was irresponsible for the act. It was proved, however, that the prisoner had shown malicious feelings against the prosecutor, and that she had wished him dead. The knife with which the wound had been inflicted bore the appearance of having been recently sharpened, and the prisoner must have reached over her daughter (the prosecutor's wife), who was sleeping in the same bed with him, in order to produce the wound. These facts were quite adverse to the supposition of the act having been perpetrated under an impulse from sleep, and the prisoner was convicted. In the case of Reg. v. Minchin (Cent Crim. Court, June 1853), in which a young woman was charged with having wounded the prosecutor during the night, the same plea was put forward, but rejected. There was nothing to
how that the prisoner was not aware of what she was doing. There was an absence of motive, but as it has been elsewhere stated, this does not create irresponsibility. In another case, Reg. v. French (Dorset Autumn Ass. 1846), it was proved that the prisoner, while sleeping in the same room, had killed the deceased, who was a stranger to him, under some delusion. There was, however, clear evidence that the prisoner was insane, and on this ground he was acquitted under the direction of the judge.

Sommambulism may become a subject of discussion under a contested policy of life-insurance, in which it may be provided that it shall be vitiated by suicide. If a man falls from a height, and is killed while in a state of somnambulism—would this be considered an act of suicide within the meaning of the policy? The proviso against suicide has been held to include only intentional killing. (See case, ante, Borradaile v. Hunter, p. 874; also, Med. Gaz. xxxvi. p. 826); and in death under these circumstances the killing cannot be said to be intentional: it can only be regarded as an accident. Therefore it is reasonable to infer that the policy would not be void. It is impossible, however, to lay down any general rules relative to cases of this description; since the circumstances attending each case will sufficiently explain how far it was likely that the act of murder or suicide had been committed during a state of somnambulism, or under an illusion continuing from a state of sleep.

THE DEAF AND DUMB.

It was formerly laid down in the old law books, that a person born deaf and dumb was by presumption of law an idiot; but in modern practice, want of speech and hearing does not imply want of capacity either in the understanding or memory, but only a difficulty in the means of communicating knowledge; and when it can be shown that such a person has understanding, which many in this condition discover by signs, he may be tried, and suffer judgment and execution. (Archbold.) A deaf and dumb person is not incompetent to give evidence unless he be also blind. He may be examined through the medium of a sworn interpreter who understands his signs. This condition does not justify restraint or interdiction, unless there be at the same time mental deficiency. A deaf and dumb person who has never been instructed, is altogether irresponsible for any action, civil or criminal. Such a person cannot even be called on to plead to a charge, when there is reason to suppose the nature of the proceedings cannot be understood. A deaf and dumb female was charged with cutting off the head of her child. By signs she pleaded not guilty, but she could not be made to understand the nature of the other proceedings against her. Upon this she was discharged, and subsequently confined as a criminal lunatic. In Reg. v. Goodman (Stafford Summer Ass. 1841), a deaf and dumb
man was convicted of theft and sentenced to imprisonment. He was made to comprehend the proceedings by signs and talking with the fingers. In *Reg. v. Brook* (Buckingham Summer Ass. 1842), the prisoner could read and write well. He was charged with feloniously cutting and stabbing. The proceedings were reported to him in writing. He was convicted, and the judge (Alderson, B.) having sentenced him to a year’s imprisonment, handed down his judgment in writing, which he recommended him to read and ponder over in prison! In *Reg. v. Jackson* (Bedford Summer Ass. 1844), Alderson, B., held, that before the evidence of a dumb witness can be received, the Court must be satisfied that he understands the obligation of an oath. It has been decided in the Ecclesiastical Courts, that the consent of a deaf and dumb person given by signs, renders a matrimonial contract valid, provided the individual have a full and proper understanding of their meaning. An incompetency to enter into contracts, or unsoundness of mind, must not be inferred to exist merely in consequence of a person’s being deaf and dumb: the case of *Harrod v. Harrod* (Vice-Chancellor’s Court, Jan. 1854), an attempt was made to deprive the plaintiff of his rights on the ground that he was an illegitimate child. The marriage of his parents took place, thirty years previously, but the marriage was said to be void, by reason of the alleged incapacity of his mother, to enter into the contract. The mother was deaf and dumb, and of more than ordinarily dull intellect. Sir W. P. Wood said there was an important difference, between “unsoundness of mind” and “dulness of intellect.” The presumption in such cases was always in favour of sanity, and the fact of a person being deaf and dumb, did not raise a presumption the other way. Experience showed, in asylums, that the deaf and dumb were not necessarily unsound. The woman had assented to the marriage in form and substance, and with a perfect knowledge of what she was doing. In the ceremony of marriage it had never been held that the repetition of the words was necessary. The woman conducted herself with great propriety before and after the marriage, and a child was born in due course. There was no ground for an issue.

**Feigned deafness and dumbness.** — From these statements it will be perceived that medical evidence is but of little importance in relation to the deaf and dumb. Indeed, there are only two cases in which this kind of evidence is likely to be called for: 1st, when there is accompanying mental deficiency, in which case the general rules, given under insanity, are applicable; and 2ndly, when there is a suspicion that the deafness and dumbness are feigned. There can be commonly no great difficulty in detecting an imposition of this kind. It will be found that the alleged deafness and dumbness did not come on until a motive existed, and that there was no apparent cause, but the very suspicious one of evading re-
sponsibility for some offence committed. The use of ether or chloroform vapour may be occasionally resorted to with advantage for the detection of an imposition. It requires great skill to maintain an imposture of this kind. Such persons are immediately thrown off their guard by addressing them in a voice a little above or a little below the common conversational tone. A change in the eye or the features will at once indicate that they hear and understand what is said. The ignorant impostor may be dealt with on the principle of "artis est celare artem," by seriously proposing in a low voice to a medical friend who may be present, the necessity for the performance of some formidable surgical operation. The production of amputating instruments has been known to have a wonderful effect! In _Reg. v. Yaquierdo_ (Herts Summer Ass. 1854), the prisoner, who was charged with wilful murder, was found by the jury to be wilfully mute. The man refused to plead, although it was obvious that he was well aware of the nature of the proceedings. No counsel could be assigned to him, as this could not be done, without prisoner's consent. He was convicted and sentenced. If the impostor can write, he may perhaps be detected by the ingenious plan adopted by the Abbé Sicard. When the deaf and dumb are taught to write they are taught by the eye. The letters are only known to them by their form, and their value in any word can be understood only by their exact relative position with respect to each other. A half-educated impostor will spell his words, or divide them incorrectly, and the errors in spelling will always have reference to sound, — thereby indicating that his knowledge has been acquired through the ear, and not alone through the eye. A man who had defied all other means of detection, wrote down several sentences, in which the misspelling was obviously due to errors produced by the sound of the words. The Abbé pronounced the man to be an impostor without seeing him, and he subsequently confessed the imposition.
INDEX.

[The principal subjects are in capitals, the cases in italics.]

ABDOMEN.
Abdomen, wounds of the, 372; sudden death from blows on the, 300.
Abortion, 570; criminal causes of, 571; from drugs, 574; appearances of, 551. 580; feigned, 580; law relative to, 581; from local applications, 579; medical responsibility in cases of, 582; proofs required, 584.
Abortives, specific, 575.
Absorbed arsenic, detection of, 89; mercury, 109.
Abstinence, long, effects of, 861.
Acceleration of death in wounds, 333.
Accidental wounds, 267.
Acephalous monsters, 604.
Acetate of lead, 114; of copper, 124; of morphia, 167.
Acetic Acid, 56.
Acid, sulphuric, 38; nitric, 45; muriatic, 50; oxalic, 50; tartaric, 57; acetic, 57; arsenious, 64; meconic, 171; prussic, 173; carbonic, 834; sulphurous, 837; hydrosulphuric, 843.
Acid poisons, 38.
Aconite, poisoning by, 212.
Aconitina, 215.
Adams, Reg. v., 933.
Adipocere, production of, in the drowned, 754.
Affiliation, 645.
Age, of the new-born child, rules for determining, 423; medical questions concerning.

ANIMAL.
601; for procreative power in the male, 666; in the female, 678; its effect on the crime of rape in relation to consent, 693; impotency depending on, 668.
Air, confined, suffocation from, 840; of drains and sewers, composition of, 847.
Alcohol, poisoning by, 194.
Alexander, Dr., case of, 74. 89.
Algaroth, powder of, 185.
Alienation, mental. (See Insanity, 866.)
Alkalies, poisoning by, 56.
Allnutt, case of, 912. 932.
Almonds, bitter, oil of, 185.
Almond flavour, 188.
Aloes, poisoning by, 144.
Ambidextrous persons, wounds produced by, 267.
Amenorrhoea, a cause of sterility, 685; of insanity, 926.
Amentia, 867.
Ammonia, poisoning by, 61; analysis, 63.
Ammonio-chloride of mercury, 110.
Amylene, noxious effects of, 200.
Analysis, articles preserved for, 32; rules for, 33. 36.
Anderson, case of, 499.
Androgyni and androgynae, 655.
Angus, Mr., case of, 565.
Animals, microscopical and chemical analysis of blood of, 317.
Animal food, poisonous effects of, 155.
Animal irritants, 152.

Asher, case of, 255.

Antimony, tartarised, poisoning by, 130; chloride of, 136. 

Aorta, wounds of the, 369.

Apnea, 720.

Aqua fortis, 45.

Aram, Euyen, case of, 384.

Armstrong, cases of the, 845.

Armstrong, Mrs., case of, 949.

Arseniates, alkaline, poisoning by, 95.

Arsenic, white, taste and solubility of, 64; symptoms caused by, 65; narcism from, 10; chronic poisoning by, 67; appearances caused, 69; death from external application of, 74; fatal doses, 72; period at which death occurs, 73; analysis as a solid, 74; in solution, 76; Marsh's process, 78; Reinsch's process, 79; analysis in organic mixtures, 81; in the tissues, 85; absorption and detection of, 88; in the soil of cemeteries, 91; sulphures of, 95.

Arsenic-eaters, 6.

Arsenic, chloride of, 93.

Arsenic acid, 95.

Arsenic, yellow and red, 95; green, 125.

Arsenious acid (see Arsenic), 64.

Arsenites, alkaline, poisoning by, 92.

Arsenite of copper, 125; in paper-hanging, 126.

Arseniuretted hydrogen, fatal effects of, 96.

Arteries, wounds of, 369.

Arterial and venous blood, 286.

Artificial inflation of the lungs, 455.

Ashford, case of, 743.

Asiatic cholera mistaken for poisoning, 16.

Asphyxia, various forms of, 720; cause of death in, 721; from gases, 831.

Atavism in insanity, 874.

Atelectasis of the lungs, 445.

Atropa belladonna, 215.

Atropine, atropia, 216.

Bacon, poisoning by, 157.

Bacon, Reg. v., 4. 86. 109.

Bagster, Miss, case of, 895.

Bainbrigge v. Bainbrigge, 906.

Baldry v. Ellis, 899.

Ball, Reg. v., 878.

Ballottement in pregnancy, 339.

Balsam, case of, 378.

Banbury peerage case, 670.

Barker, case of, 737.

Barton, case of, 903.

Bastardy, adulterine, law regarding, 608.

Battley's sedative solution, 168.

Bayley, Reg. v. 231.

Bearfoot (hellebore), 209.

Belladonna, 215.

Berri, Duke de, case of, 350.

Berryman, Reg. v. 568.

Bestiality, 718.

Bichloride of mercury, 98.

Bichromate of potash, 142.

Bicyanide of mercury, 112.

Binoxalate of potash, 56.

Birth, proof of, in criminal law, 471; in civil law, 588; concealment of, 566; date of, 588.

Births, plural, 602; posthumous, 601; premature, 615; protracted, 685.

Birchisile v. Vardell, 608.

Bishop and Williams, case of, 766. 880.

Bismuth, poisoning by, 142.

Bitter Almonds, 185.

Bitter-sweet, effects of, 192.

Black drop, 168.

Bladder, ruptures of the, 348. 375.
Blandy, case of, 21.
Blewitt, case of, 413.
Blight, case of, 275.
Blistering fly, poisoning by, 152. (See Cantharides.)
Blood, on weapons, 278; marks of, in death from wounds, 282; arterial and venous, 286; tests for, 306; human and animal, 315; microscopical examination of, 317; in cases of abortion, 587.
Blood-stains, chemical examination of, 304; on linen, 306; distinguished from rust and fruit stains, 309; removal of, 311; on weapons, 312; date of, on articles of dress, 306; microscopical examination of, 317; in cases of rape, 659.
Blows or falls, injuries produced by, 256.
Blue-rocket, poisoning by, 212.
Blue vitriol, 122.
Bocarne, Count, case of, 217.
Body, examination of the, in poisoning, 29; exhumation of the, 31; combustibility of the, 416; length and weight of the, in new-born children, 426; buoyancy of the, in drowning, 749; evidence from the position of the, in hanging, 794.
Bolam, case of, 291.
Bolton, case of, 227.
Bones, fractures of the, 357; of the foetus, analysis of, 567.
Born alive, signification of, in civil and criminal law, 471.
588.
Borradaile v. Hunter, 938.
Boughton, Sir T., case of, 15.
Bouyer, case of, 209.
Brain, extravasation of blood on the, 356; locomotion after severe injury to the, 344.

Brain, case of, 430.
Bread, mouldy, 149.
Breasts, changes in the, in pregnancy, 534.
Brick-kilns, the vapour of, 839.
Brixy, case of, 926.
Brough, Reg. v., 927.
Brown, Reg. v., 851.
Bryant, case of, 255.
Buoyancy of the body in drowning, 749.
Buranelli, Reg. v., 933.
Burgess, case of, 353.
Burke and McDougall, case of, 830.
Burnett’s fluid, 138.
Burning, homicidal, 415.
Burns, Miss, case of, 565.
Burns and scalds, 403; by corrosive liquids, 418; from lightning, 853.
Burrows, Reg. v., 175.
Burton, case of, 88.
Bury, case of, 690.
Butcher, case of, 334.
Butler, case of, 231.
Butter of antimony, 136.
Butterfield, case of, 21.
Byrne, case of, 805.
Byron, case of, 523.

Cadaveric lividity, 248; spasm in drowning, 733, 741.
Caesarean extraction, 599.
Cairns v. Murienski, 908.
Calamine, 139.
Calder, case of, 575.
Calomel, poisoning by, 110; salivation from small doses of, 101.
Camphor, poisoning by, 193.
Camplin, case of, 710.
Canalis venosus, 479.
Cancre of the leg, 102.
Canker of the mouth, 102.
Cantharides, symptoms and appearances, 152; fatal doses, 154.
Capacity, testimonial, 888; testamentary, 900; test of, 901.
Carbonate of potash and soda, 60; of ammonia, 62; of lead, 118; of copper, 124; of zinc, 139.
Carbonic acid, symptoms and appearances, caused by, 833; analysis, 835; death from evolution of, by acids, 834.
Carburetted hydrogen, 841.
Carbonic oxide, 841.
Carminative, Dalby's, 166.
Carinal knowledge, 692.
Carnt, case of, 744, 757.
Carob-beans, 150.
Carotid arteries, locomotion after wounds of the, 347.
Cashin, Miss, case of, 419.
Castor seeds, poisoning by, 147.
Catamenia, (See Menstruation,) 678.
Catsup, poisoning by, 220. (See Mushrooms.)
Caustic alkalies, poisoning by, 58.
Cowley, case of, 379.
Cemeteries, 404.
COLICA.

Colica pictorum, 119.
Colier, case of, 398.
Colocyth, action of 144.
Combustion, human, alleged, 413.
Commissions of lunacy, 889.
Compos mentis, 889.
Concealed sex, 663.
Concealment of birth, 566.
Concealment of pregnancy, 545.
Concealment of delivery, 550.
Conception, date of, 613.
Concussion of the brain, 353; of the spinal marrow, 362.
Condé, Prince de, case of the, 798.
Confectionery, poisonous, 126.
Confined air, effects of, 840.
Conium, poisoning by, 209.
Contusions on the living and dead, 243.
Cook, case of, 410.
Copper, poisoning by, 122; salts of, 124; in articles of food, 128.
Copperas, poisoning by, 140.
Copper, sulphate of, poisoning by, 122.
Cord, umbilical, death from laceration and compression of the, 489; strangulation by the, 514.
Cord, mark of the, in hanging, 777.
Corpora lutea, 558.
Corrosive liquids, burns from, 418.
Corrosive poisons, 9.
Corrosive Sublimate, solubility, taste, and symptoms, 96; salivation an effect of, 100; appearances caused by, 103; fatal dose, period of death, 104; chemical analysis, 105.

DELAFOSSE.

Courtesy, tenancy by, 595.
Courvoisier, case of, 284, 920.
Cowper, Spencer, case of 746. 750.
Cox, case of, 829.

Deformities, evidence from, 644.
Delafosse v. Fortescue, case of, 707.
Delirium, mistaken for insanity, 869. 902; suicide in, 941.
Delirium tremens, 337. 951.
Delivery, protracted, death of the child from, 489; sudden, in the erect posture, 498. 505; locomotion and exertion after, 499; signs of, in the living, 550; at a remote period, 552; feigned and unconscious, 553; during sleep, 555; signs of, in the dead, 557; of moles and hydatids, 563; premature, 582.
Delusion the main character of insanity, 866. 905; connection of, with the acts of the insane, 920; in reference to testamentary capacity, 903.
De lunatico inquirendo, 889.
Dementia, 871; senile, 907.
D'Eon Chvalier, case of, 660.
Depilatories, arsenical, 96.
De ventre inspiciendo, writ of, 541.
Destructive thing, meaning of, in law, 5.
Devonald v. Hope, 540.
Diaphragm, ruptures of the, 347; wounds of the, 370.
Dicephalous monsters, 604.
Digitalis, poisoning by, 208.
Dipsomania, 947.
Direction of wounds, evidence from, 266.
Discharge of lunatics, 886.
Disease, action of poisons influenced by, 12; mistaken for poisoning, 16; latent, death from, in wounds, 323; accelerating death from personal injuries, 333.
Disfigured flesh, poisonous, 157.
Dislocations, 227. 384.
Disomatosus monsters, 604.
Distinction of sex, 655.
Divorce, evidence in suits of, 689.

Dixon, case of, 377.
Docimasia pulmonaris, 441.
(See Hydostatic Test.)
Dolcets, circulationis, 474.
Dodd, Reg. v., 257.
Dolley, case of, 868.
Dore and Spry, case of, 70.
Doubtful sex, 657.
Douglas peerage case, 642.
Dover's powder, 167.
Drains and sewers, effluvia of, 847.
Drory, case of, 812.
Drowning — in child-murder, 496; cause of death in, 722. 724; period at which death occurs, 726; treatment, 729; appearances, 732; was death caused by, 740; buoyancy of the body, 749; presumption of survivorship, 753; summary of proofs, 755; origin of marks of violence in cases of, 758; homicidal or suicidal, 762; accidental, in shallow water, 764; from partial immersion, 765; weights attached to the body in, 767.
Drunkenness, civil and criminal responsibility in cases of, 947; restraint in cases of, 949.
Dryden v. Fryer, 907.
Ductus arteriosus, closure of, 475.
Dulcamara, 192.
Dumb, responsibility of the, 953.
Durnell v. Corfield, 907.
Dyce Sombre's case, 896.
Dyes, mistaken for blood, 309.
Dyer's spirit, poisoning by, 140.
Dying declarations, rules respecting the reception of, 230.
Eager v. Grimwood, 624.
Effluvia of drains and sewers, 847; mephitic, 850.
Eccentricity.

Eccentricity mistaken for insanity, 869; in wills, 905.

Ecchymosis, nature of, 240; seat of, and change of colour in, 242; evidence from, 243; production of, after death, 244; various causes of, in the living, 246; spontaneous, in the dead, 248; not always a result of contusion, 251; in strangulation by the umbilical cord, 514; in hanging, 779; in death from lightning, 854.

Edwarda, case of, 663. 903.

Effluvia of drains and sewers, 847.

Elder, case of, 945.

Electric fluid, action of, 851.

(See Lightning.)

Elkington, Dr., case of, 167.

Ellison, case of, 278.

Embryo, characters of, to the sixth month, 562.

Emerald green, poisoning by, 195.

Emetic tartar, poisoning by, 130.

Epispadias, 674.

Ergot of rye, 575.

Erysipelas following wounds, 337.

Essex, Earl of, case of, 278.

Ether, poisoning by, 195.

Evidence, identity of articles for analysis, 32; notes, when and how used in, 34; of poisoning in the living, 11; in the dead, 18; circumstantial and presumptive, in wounds, 273.

Exhalations from the dead, 849.

Exhumation of bodies, 31.

Extra quatuor maria, rule of, 607.

Extra-uterine pregnancy, 586.

Extravassation of blood on the brain, 356.

Face, wounds of the, 361.

Fama clamosa, 620.

Farmer, case of, 921.

Fasting, long, effects of, 861.

Featherston, Reg. v., 544.

Features, evidence from, 642.

Feigned poisoning, 17; wounds, 291; pregnancy, 540; menstruation, 533; delivery, 553; insanity, 876; abortion, 580; deafness and dumbness, 954.

F:Jo de se, 937.

Fife, Mr., case of, 941.

Fire-arms, examination, 401.

Fire, wounds caused by, 411.

Fish-poison, 156.

Fish v. Palmer, 590.

Flesh, diseased, poisoning by, 157.

Flogging, death from, 301.

Fly-powder and water, death from, 94.

Fumicide, 570. (See Abortion.)

Fustus, characters of, from conception to the sixth month, 562; from the sixth to the ninth month, 423.

Food, poisonous, 154.

Fool's parsley, poisoning by, 210.

Foramen ovale, closure of the, 479.

Foster, case of, 66.

Fowler's mineral solution, 92.

Fox, case of, 541.

Foxglove, poisoning by, 208.

Fractures, 357, 504; of the skull, 380; of the spine, 362; accidental, in the drowned, 760.

Fragilitas ossium, 381.

Franck, Dr., case of, 818.
Gall-bladder, ruptures of the, 373.
Gallip, case of, 912.

Harvey, Reg. v., 232.
Hartshorn, poisoning by, 62.
Hatton, case of, 417. 283.
Haydon, case of, 5. 63.
Haynes, case of, 234. 584.
Haywood, Mr., case of, 46.
Hazell, case of, 282.
Head, wounds of the, 344. 352.
Heart, wounds of the, 345. 366.
Heathcote, case of, 624.
Hellebore, poisoning by, 4. 208.
Hemiplegia, its effect on the mind, 900; its influence on virile power, 675.
Hemlock, poisoning by, 209.
Hembane, poisoning by, 191.
Henderson, case of, 292.
Hereditary transmission of insanity, 873; of suicide, 942.
Hermaphroditism, 654.
Hernia, phrenic, 371.
Haywood, case of, 277. 824.
Hierapica, 145.
Hill v. Philip, case of, 880.
Hill, Reg. v., 888.
Hobbs, case of, 350.
Hoffman's liquor, analysis of, 196.
Holden, case of, 949.
Holloway's pills, 145.
Homicidal wounds, characters of, 258; homicidal burning mistaken for spontaneous, 415.

HOMICIDAL MONOMANIA, 913; causes of, and symptoms of, 914; legal tests of, 917; medical tests of, 916; summary of characters, 923.
Hooper, case of, 638.
Horder, case of, 512.
Hornshaw, case of, 775.
Howell, Reg. v., 230.
Hull, case of, 353.
Hulme, case of, 332.
Hume, case of, 697.
Human combustion, 413.

IMPOTENCY. 965

Hunger, death from, 861. (See Starvation.)
Hunt, case of, 543.
Hutchins, case of, 654.
Hydatids, uterine, 563.
Hydrochloric acid, 50. (See Muriatic Acid.)
Hydrocyanic acid, poisoning by, 173. (Prussic Acid.)
Hydrogen arseniureted, 96.
Hydrogen test for arsenic, 78.
HYDROSTATIC TEST, 441; objections to the, from sinking of the lungs, 449; from putrefaction and artificial inflation, 452; erroneous notions respecting the, 462; general conclusions respecting the employment of, 469.
Hydrosulphuret of ammonia, action of vapour of, 849.
Hydrosulphuric acid gas, 843.
Hymen, evidence derived from the, in rape, 694; as a sign of virginity, 706.
Hyoscyamus, poisoning by, 191.
Hypospadias, 674.
Identity, of substances for analysis, 32; from the flash of gunpowder, 400.
Idiocy, 871.
Idiosyncrasy in poisoning, 7.
Illusions in insanity, 868; in drunkenness, 948.
Imbecility, 871; senile, 907.
Immaturity, death of the child from, 489; evidence from, in cases of legitimacy, 622.
Impediments, canonical, to marriage, 687.
Impotency, 665; from age, 668; from local disease and malformation, 671; from general disease, 674; from moral causes, 678; as a ground of divorce, 689.

3 Q 3
Incompetency, mental, medical tests of, 892.

Indigo, sulphate of, poisoning by, 44.

Infanticide, 421; proofs of, life before respiration, 422; after respiration, 434; statistical tests in, 437; Ploucquet's tests in, 441; legal proofs of, 463; proofs of live birth in, 471; survivorship of the child in cases of, 483; natural causes of death in, 487; violent causes of death, 493; summary of medical proofs in, 527.

Infants, action of opium on, 163.

Inflation, artificial, 455.

Inheritance, questions relating to, 588, 642.

Insane, responsibility of the, in civil cases, 898; in criminal cases, 908; effects of cold on the, 868.
